Economic problems continued to challenge Nixon in 1973. In January, he ended most of the government-required limits that had been placed on wage and price increases in 1971. But prices soared, and another brief use of controls resulted in a shortage of beef and other foods. By the end of 1973, inflation had risen 8.8 percent, the largest increase in any year since 1947.

Also in 1973, a fuel shortage led to reduced supplies of oil for home heating and industry and to gasoline rationing in a number of states. In 1974, Congress approved Nixon's proposal to set up a Federal Energy Administration to deal with the energy shortage.

The Watergate scandal hit the Nixon administration during 1973. It arose from a break-in at the Democratic Party headquarters in the Watergate building complex in Washington, D.C., on June 17, 1972. Employees of Nixon's 1972 reelection committee were arrested in the break-in and convicted of burglary. Early in 1973, evidence was uncovered that linked several top White House aides with either the break-in or later attempts to hide information related to it.

Nixon insisted that he did not participate in the Watergate break-in or the cover-up. In addition, he promised a full investigation of the case. In May, Archibald Cox, a Harvard Law School professor, was named to head the investigation as the special prosecutor.

In July, a Senate investigating committee learned that Nixon had secretly made tape recordings of conversations in his White House offices since 1971. The president said that he taped the conversations to preserve ar accurate record of his administration. Cox and the Senate committee asked Nixon to give them certain tapes that they believed could aid their investigations. Nixon refused. He argued that the Constitution gives a president the implied right to maintain the confidentiality of private presidential conversations. Nixon said the loss o that right would endanger the presidency.

In August, Cox and the committee filed petitions in court to obtain the tapes. U.S. District Court Judge John Sirica decided to review the tapes himself and ordered Nixon to give them to him. Nixon appealed the order, but a U.S. court of appeals supported Sirica.

On October 19, Nixon offered to supply summaries o the tapes to the Senate committee and to Cox. Cox refused, arguing that summaries would not be regarded as proper evidence in court. Nixon ordered Attorney General Elliot L. Richardson to fire Cox, but Richardson refused and resigned, as did Deputy Attorney General William G. Ruckelshaus. Nixon named Robert H. Bork acting attorney general, and Bork fired Cox. Leon Jaworski, a noted Texas attorney, later succeeded Cox. Bu Nixon's actions resulted in a move for his impeachment

The resignation of Agnew on Oct. 10, 1973, further stunned the nation. Earlier that year, federal officials ha begun to investigate Agnew in connection with charge of graft in Maryland. They uncovered evidence he had accepted illegal payments as an officeholder in Maryland and as vice president. After he resigned, Agnew pleaded *nolo contendere* (no contest) to a charge that h had cheated on his federal income tax payment for 196

National Archives

During the Watergate scandal, Nixon appeared on TV with transcripts of tape recordings of White House conversations. He refused to give the actual tapes to investigators.

Quotations from Nixon

The following quotations come from some of Richard Nixon's speeches and writings.

Crises can indeed be agony. But it is the exquisite agony which a man might not want to experience again—yet would not for the world have missed.

Introduction to *Six Crises*, published in 1962

We have found ourselves rich in goods, but ragged in spirit; reaching with magnificent precision for the moon, but falling into raucous discord on earth. We are caught in war, wanting peace. We are torn by divisions, wanting unity.

First Inaugural Address, Jan. 20, 1969

If when the chips are down, the world's most powerful nation ... acts like a pitiful, helpless giant, the forces of totalitarianism and anarchy will threaten free nations ...throughout the world.

Speech announcing invasion of Cambodia, April 30, 1970

Let us reject the narrow visions of those who would tell us that we are evil because we are not yet perfect ... that all the sweat and toil and sacrifice that have gone into the building of America were for naught because the building is not yet done. Let us see that the path we are traveling is wide, with room in it for all of us, and that its direction is toward a better nation in a more peaceful world.

State of the Union Address to Congress, Jan. 20, 1972

Always give your best, never get discouraged, never be petty; always remember, others may hate you. Those who hate you don't win unless you hate them. And then you destroy yourself.

Final speech before leaving office, Aug. 9, 1974

Gerald Ford became vice president in 1973, after Spiro Agnew resigned. Nixon and Mrs. Ford watched as Chief Justice Warren Burger administered the oath of office.

J.P. Laffont, Sygma

'ears later, in 1981, a Maryland court ordered Agnew to ›ay the state the amount of the bribes it declared he had ccepted, plus interest. In 1983, Agnew paid $268,482.

Nixon became the first president to appoint a vice ›resident under procedures established by the 25th ımendment to the Constitution. He named House Mi›ority Leader Gerald R. Ford as Agnew's successor, and ord became vice president on Dec. 6, 1973.

The impeachment hearings began before the House ɹdiciary Committee in October 1973. The committee ad obtained from the president several tapes and editd transcripts of many tapes of White House conversaons. The committee issued *subpoenas* (legal demands) ɔr additional tapes, but the president resisted and took is case to the Supreme Court.

In July 1974, before the court made its decision, a maɔrity of the committee members voted to recommend ıree articles of impeachment against Nixon. The first arcle charged that the president obstructed justice by ʋithholding evidence, counseling his aides to give false ɜstimony, and otherwise interfering with the Watergate ıvestigation. The second impeachment article charged ıat Nixon abused presidential powers, and the third acused him of refusing to obey subpoenas.

In late July, the Supreme Court ruled that Nixon had to ırn over the tapes. Nixon made the tapes public on Auust 5. One tape revealed that he had spoken of a coverp as early as June 23, 1972, six days after the burglary. epublican congressional leaders warned Nixon that he ıced almost certain impeachment by the House of Repɜsentatives and removal from office by the Senate.

Resignation and pardon. Nixon told his family on Auust 7 that he planned to resign. He announced his deciion to the American people in a nationwide television ddress the next evening. On August 9, with about 2 $\frac{1}{2}$ ɜars remaining in his second term, Nixon submitted his ɜsignation as president. At noon that day, Vice Presient Gerald R. Ford was sworn in as the 38th president.

Nixon's resignation ended the prospect of a struggle ʋer impeachment. But many Americans continued to ɜbate whether he should be prosecuted for his role in e cover-up. On September 8, Ford granted Nixon a ırdon for all federal crimes Nixon may have committed hile president. Ford said he made the decision to "reconcile divisions in our country and heal the wounds that had festered too long."

Later years

After leaving office, Nixon returned to San Clemente. He avoided active participation in politics and spent much of his time playing golf and writing. Nixon maintained a strong interest in international affairs, and his opinions on U.S. foreign policy were highly regarded by many people, including both Democratic and Republican presidents who served after him.

In 1978, Nixon published *RN: The Memoirs of Richard Nixon.* In 1980, he moved to New York City and published *The Real War,* a book on U.S. foreign policy. Nixon moved to Saddle River, New Jersey, in 1981 and to Park Ridge, New Jersey, in 1991. He also wrote *Leaders* (1982), *Real Peace: A Strategy for the West* (1983), *No More Vietnams* (1985), *1999: Victory Without War* (1988), *In the Arena* (1990), *Seize the Moment* (1992), and *Beyond Peace* (1994).

In 1990, the Richard Nixon Library and Birthplace opened in Yorba Linda, California. It includes a museum. Nixon's wife, Pat, died of lung cancer on June 22, 1993, at their home in Park Ridge. On April 18, 1994, Nixon suffered a stroke at home just before dinner and was taken by ambulance to a hospital in New York City. Three days later, he lapsed into a coma. He died the following day, April 22. Nixon and his wife are buried on the grounds of the Richard Nixon Library and Birthplace, near the house he was born in. Melvin Small

Nizhniy Novgorod, *NIHZH nee NAHV guh RAHD,* (pop. 1,361,500), is an industrial center in Russia. It lies at the fork of the Volga and Oka rivers (see **Russia** [political map]). Nizhniy Novgorod is one of the oldest cities in Russia and is known as the *Cradle of the Russian Empire.* The city's upper part contains a fortress and historic cathedrals. The lower town is the industrial section. One of Russia's largest automobile factories is in Nizhniy Novgorod. Other products include locomotives, airplanes, machine tools, and chemicals.

Nizhniy Novgorod was an important commercial center in the Middle Ages, a period in history that lasted from about the 400's through the 1400's. In this period, west-east travel along the Oka River and through a low pass in the Ural Mountains met north-south travel on the Volga River. In 1932, when Russia was a republic of the Soviet Union, the city was renamed Gorki in honor of the Russian writer Maxim Gorki. The city was renamed Nizhniy Novgorod in 1990, about a year before the Soviet republics became independent. Roman Szporluk

Nkrumah, *ehn KROO muh,* **Kwame,** *KWAH mee* (1909-1972), was president of Ghana from 1960 to 1966. Army leaders ousted him in 1966, and Nkrumah went into exile in nearby Guinea. President Sékou Touré of Guinea made Nkrumah Guinea's honorary president.

As president of Ghana, Nkrumah worked to develop the economy and improve living conditions. He promoted industrialization, introduced health and welfare programs, and expanded the educational system. But Nkrumah made enemies with the methods he used to achieve these goals. He imprisoned his opponents. Ghana's economy began to weaken, and corruption became widespread. Army leaders took over the government while Nkrumah was visiting China.

Nkrumah was born in Nkroful, Ghana. He led his country's drive for independence from the British in the 1950's. He was prime minister of the Gold Coast and kept that office when the colony became Ghana, an independent country, in 1957. Immanuel Wallerstein

NLRB. See National Labor Relations Board.

No-fault divorce. See Divorce.

No-fault insurance is a type of automobile accident insurance that was first proposed in the 1960's. It provides that if a driver, passenger, or pedestrian is injured an insurance company—usually the driver's company—must pay, no matter who caused the accident. Injured people receive payment for medical costs and loss of income. However, many no-fault plans restrict a victim's right to sue for pain and suffering or other nonfinancial damage. Such restrictions forbid a suit for nonfinancial damage unless the medical expenses exceed a certain amount or the victim was disfigured, disabled, or killed. Many other types of insurance, including fire, health, and life insurance, have always been no-fault.

Supporters of no-fault automobile insurance believe it corrects flaws in the older system, which requires that blame be determined before claims are settled. Many victims of automobile accidents go through costly legal battles and wait for years before receiving payment. Insurance companies fight large claims more vigorously than small ones. As a result, many seriously injured victims collect little or nothing, while many with minor injuries get relatively large settlements. People who favor no-fault insurance say it brings quicker settlements and fairer distribution of payments. They also believe motorists pay less for insurance because there are fewer large damage suits and expensive court battles.

Opponents of no-fault insurance argue that it is unfa[ir] to release careless drivers from the responsibility for i[n]juries they cause. They also say that no-fault plans do n[ot] reduce insurance costs because more injured people receive benefits.

In 1970, Massachusetts became the first state to adopt no-fault insurance plan. A number of other states later dopted no-fault plans. Some had modified plans, withut restricted suits. Dan R. Anderson

lo play. See **Drama** (Asian drama); **Japanese literature** The medieval period).

loah, *NOH uh,* according to the Bible, was the only ghteous, God-fearing man of his time. Genesis 6-9 tells nat he was chosen by God to keep some people and nimals alive during the Deluge, or great Flood. Noah varned people for 120 years that the Flood was coming. uring that time, he built a ship, called the ark, which vas 450 feet (137 meters) long. He took into the ark his imily, and enough birds and animals to repopulate the arth. The rain poured for 40 days and 40 nights (Gen. :12, 24).

The waters dropped enough 150 days after the Flood tarted that the ark was able to rest on the mountains of rarat (see **Ararat**). Noah let loose a raven that did not eturn. Then he sent out a dove, and it returned because could find no place to perch. He sent out the dove two nore times. On the second flight, it returned with an live branch in its mouth.

Noah and the animals left the ark later to begin a new fe. Noah offered sacrifice to God for deliverance, and od promised him that He would never send another ood to destroy the earth. He made the rainbow a sign f that promise. He commanded Noah and his descendnts to respect human life and to punish murder with ne death penalty.

Noah's sons were Shem, Ham, and Japheth. Shem beame father of the *Semitic* peoples, including the Jews nd the Arabs. Ham was the father of the Hamitic peoles. Japheth became the father of peoples of Asia Mior and Europe. In traditions originally unrelated to the ood, Noah is pictured as a gardener and is credited ith the discovery of wine (Gen. 9:18-27).

Carole R. Fontaine

obel, *noh BEHL,* **Alfred Bernhard** (1833-1896), a wedish chemist and industrialist, invented dynamite. e established the Nobel Prizes, using profits from the nanufacture of chemical explosives to provide funds for ne prizes (see **Nobel Prizes**).

Nobel began experimenting with nitroglycerin in his ther's factory. Liquid nitroglycerin is a powerful explove that is dangerous because of its tendency to exode when handled roughly. Nobel tried many ways of aking nitroglycerin safe to use. The best way, he disvered, was to mix it with a fine, porous powder called *eselguhr.* Nobel named e resulting powdery ixture dynamite (see **Dynamite**). He received a tent for it in 1867. Conruction and mining comnies and the military orered large quantities of ynamite because of its lative safety and explove power. Nobel set up ctories around the orld, and sales of dynaite and other explosives ought him great wealth.

Amer. Swedish News Exch., Inc.
Alfred Nobel

His other chemical research provided valuable information on the preparation of artificial forms of rubber, leather, silk, and precious stones.

Nobel was born on Oct. 21, 1833, in Stockholm and was educated in St. Petersburg, Russia, where his family had moved in 1842. He traveled widely as a young man and became fluent in five languages. Nobel was greatly interested in literature and wrote poetry, novels, and plays in his spare time. In his will, Nobel set up a fund of about $9 million. The interest from the money was to be used to award annual prizes to people whose work most benefited humanity. Nobel wanted the profits from explosives to be used to reward human ingenuity. The Nobel Prizes, first awarded in 1901, remain the most honored prizes in the world. Melvyn C. Usselman

Halasz, Nicholas. *Nobel: A Biography of Alfred Nobel.* Orion Pr., 1959.

Nobel Prizes, *noh BEHL,* are awarded each year to people, regardless of nationality, who have made valuable contributions to the "good of humanity." In his will, the Swedish inventor Alfred Nobel directed that the income from his $9-million estate be used to fund five annual prizes. The awards are given for the most important discoveries or inventions in the fields of physics, chemistry, and physiology or medicine; the most distinguished literary work of an idealistic nature; and the most effective work in the interest of international peace. The prizes were first presented in 1901. A sixth prize—the Bank of Sweden Prize in Economic Sciences in Memory of Alfred Nobel—was first awarded in 1969. This prize was established by the Bank of Sweden and is funded by the bank. The value of each of the six prizes is about $1 million.

The Royal Swedish Academy of Sciences in Stockholm, Sweden, chooses the physics, chemistry, and economics winners. The Nobel Assembly at the Karolinska Institute in Stockholm awards the prize for medicine. The Swedish Academy in Stockholm awards the prize for literature. The Norwegian Nobel Committee elected by the Norwegian *Storting* (parliament) awards the prize for peace.

A candidate may not apply directly for a prize. A qualified person must submit each name in writing. For the literary prize, the Swedish Academy considers only works that have appeared in print. The academy usually selects an author for his or her complete work rather than for one book.

The organizations that award the prizes appoint 15 deputies who elect a board of directors. The board holds office for two years and administers the funds. Prizewinners receive their awards on December 10, the anniversary of the death of Alfred Nobel. The peace prize is awarded in Oslo, Norway. The other prizes are presented in Stockholm. Two or three people may share a prize. Sometimes, prizes are not awarded or are awarded in a later year.

Critically reviewed by the Nobel Foundation

There is a biography in *World Book* of each prizewinner whose name is marked with an asterisk in the tables on the following pages.

Literature

Nobel Prizes consist of a medal and a cash award. Prizes are awarded for achievement in chemistry, physics, physiology or medicine, literature, world peace, and economics. The front side of each medal has a bust of Alfred Nobel, a Swedish chemist who established most of the prizes in the late 1800's. The bust is the same on the physics and chemistry, physiology or medicine, and literature medals, *shown here.* The physics and chemistry medals have identical back sides. The front and back sides of the peace and economics medals are shown at the far right.

Nobel Prizes in physics

1901 *Wilhelm C. Roentgen (German) for discovering X rays.
1902 *Hendrik Antoon Lorentz and *Pieter Zeeman (Dutch) for discovering the Zeeman effect of magnetism on light.
1903 *Antoine Henri Becquerel (French) for discovering natural radioactivity and *Pierre and Marie Curie (French) for their research on radiation.
1904 Baron Rayleigh (British) for studying the density of gases and discovering argon.
1905 Philipp Lenard (German) for studying the properties of cathode rays.
1906 *Sir Joseph John Thomson (British) for studying electrical discharge through gases.
1907 *Albert A. Michelson (American) for his design of precise optical instruments and for the accurate measurements he obtained with them.
1908 Gabriel Lippmann (French) for his method of color photography.
1909 *Guglielmo Marconi (Italian) and Karl Ferdinand Braun (German) for developing the wireless telegraph.
1910 Johannes D. van der Waals (Dutch) for studying the relationships of liquids and gases.
1911 Wilhelm Wien (German) for his discoveries on the heat radiated by black objects.
1912 Nils Dalén (Swedish) for inventing automatic gas regulators for lighthouses.
1913 Heike Kamerlingh Onnes (Dutch) for experimenting with low temperatures and liquefying helium.
1914 Max T. F. von Laue (German) for using crystals to measure X rays.
1915 *Sir William Henry Bragg and Sir William L. Bragg (British) for using X rays to study crystal structure.
1916 No award
1917 Charles Barkla (British) for studying the diffusion of light and the radiation of X rays from elements.
1918 *Max Planck (German) for stating the quantum theory of light.
1919 Johannes Stark (German) for discovering the Stark effect of spectra in electric fields.
1920 Charles E. Guillaume (French) for discovering nickel-steel alloys with slight expansion, and the alloy invar.
1921 *Albert Einstein (German) for contributing to mathematical physics and stating the law of the photoelectric effect.
1922 *Niels Bohr (Danish) for studying the structure of atoms and their radiations.
1923 *Robert A. Millikan (American) for measuring the charge on electrons and working on the photoelectric effect.
1924 *Karl M. G. Siegbahn (Swedish) for working with the X-ray spectroscope.
1925 James Franck and *Gustav Hertz (German) for stating laws on the collision of an electron with an atom.
1926 Jean Baptiste Perrin (French) for studying the discontinuous structure of matter and measuring the sizes of atoms
1927 Arthur H. Compton (American) for discovering the Compton effect on X rays reflected from atoms, and Charles T. R. Wilson (British) for discovering a method fo tracing the paths of ions.
1928 Owen W. Richardson (British) for studying thermionic effect and electrons sent off by hot metals.
1929 *Louis Victor de Broglie (French) for discovering the wave character of electrons.
1930 *Sir Chandrasekhara Venkata Raman (Indian) for discovering a new effect in radiation from elements.
1931 No award
1932 *Werner Heisenberg (German) for founding quantum mechanics, which led to discoveries in hydrogen.
1933 *Paul Dirac (British) and *Erwin Schrödinger (Austrian) for discovering new forms of atomic theory.
1934 No award
1935 *Sir James Chadwick (British) for discovering the neutron.
1936 *Carl David Anderson (American) for discovering the positron, and Victor F. Hess (Austrian) for discovering cosmic rays.
1937 Clinton Davisson (American) and George Thomson (British) for discovering the diffraction of electrons by crystals.
1938 *Enrico Fermi (Italian) for discovering new radioactive elements beyond uranium.
1939 *Ernest O. Lawrence (American) for inventing the cyclotr and working on artificial radioactivity.
1940-1942 No award
1943 Otto Stern (American) for discovering the molecular be method of studying the atom.
1944 Isidor Isaac Rabi (American) for recording the magnetic properties of atomic nuclei.
1945 *Wolfgang Pauli (Austrian) for discovering the exclusion principle (Pauli principle) of electrons.
1946 *Percy Williams Bridgman (American) for his work in the field of very high pressures.
1947 *Sir Edward V. Appleton (British) for exploring the ionosphere.
1948 Patrick M. S. Blackett (British) for his discoveries in cosm radiation.
1949 *Hideki Yukawa (Japanese) for his prediction of the existence of mesons.
1950 Cecil Frank Powell (British) for his photographic metho of studying atomic nuclei and his discoveries concerni mesons.
1951 *Sir John D. Cockcroft (British) and *Ernest T. S. Walton (Irish) for work on the transmutation of atomic nuclei b artificially accelerated atomic particles.

Nobel Prizes in physics (continued)

1952 *Felix Bloch and *Edward Mills Purcell (American) for developing magnetic measurement methods for atomic nuclei.

1953 Frits Zernike (Dutch) for inventing the phase contrast microscope for cancer research.

1954 *Max Born (German) for research in quantum mechanics, and Walther Bothe (German) for discoveries he made with his coincidence method.

1955 *Willis E. Lamb, Jr. (American), for discoveries on the structure of the hydrogen spectrum, and Polykarp Kusch (American) for determining the magnetic moment of the electron.

1956 *John Bardeen, *Walter H. Brattain, and *William Shockley (American) for inventing the transistor.

1957 *Tsung Dao Lee and *Chen Ning Yang (American) for work disproving the law of conservation of parity.

1958 Pavel A. Cherenkov, Ilya M. Frank, and Igor Y. Tamm (Soviet) for discovering and interpreting the Cherenkov effect in studying high-energy particles.

1959 Emilio Segrè and Owen Chamberlain (American) for their work in demonstrating the existence of the antiproton.

1960 Donald A. Glaser (American) for inventing the bubble chamber to study subatomic particles.

1961 Robert Hofstadter (American) for his studies of nucleons, and *Rudolf L. Mössbauer (German) for his research on gamma rays.

1962 Lev Davidovich Landau (Soviet) for his research on liquid helium.

1963 *Eugene Paul Wigner (American) for his contributions to the understanding of atomic nuclei and the elementary particles, and *Maria Goeppert Mayer (American) and *J. Hans Jensen (German) for their work on the structure of atomic nuclei.

1964 Charles H. Townes (American) and *Nikolai G. Basov and *Alexander M. Prokhorov (Soviet) for developing *masers* and *lasers*.

1965 Sin-itiro Tomonaga (Japanese) and Julian S. Schwinger and *Richard P. Feynman (American) for basic work in quantum electrodynamics.

1966 Alfred Kastler (French) for his work on the energy levels of atoms.

1967 Hans Albrecht Bethe (American) for his contributions to the theory of nuclear reactions, especially his discoveries on the energy production in stars.

1968 Luis W. Alvarez (American) for his contributions to the knowledge of subatomic particles.

1969 *Murray Gell-Mann (American) for his discoveries concerning the classification of nuclear particles and their interactions.

1970 *Hannes Olof Gösta Alfvén (Swedish) for his work in *magnetohydrodynamics*, the study of electrical and magnetic effects in fluids that conduct electricity, and Louis Eugène Félix Néel (French) for his discoveries of magnetic properties that applied to computer memories.

1971 *Dennis Gabor (British) for his work in *holography*, a method of making a three-dimensional photograph with coherent light produced by a laser.

1972 *John Bardeen, Leon N. Cooper, and John Robert Schrieffer (American) for their work on *superconductivity*, the disappearance of electrical resistance.

1973 Ivar Giaever (American), Leo Esaki (Japanese), and Brian Josephson (British) for their work on the phenomena of electron "tunneling" through semiconductor and superconductor materials.

1974 Antony Hewish (British) for his decisive role in the discovery of pulsars, and Sir Martin Ryle (British) for his use of small radio telescopes to "see" into space with great accuracy.

1975 L. James Rainwater (American) and Aage N. Bohr and Ben R. Mottelson (Danish) for their work on the structure of the atomic nucleus.

1976 Burton Richter and Samuel Chao Chung Ting (American) for their discovery of an elementary nuclear particle called the *psi*, or *J, particle*.

1977 Philip W. Anderson and John H. Van Vleck (American) and Sir Nevill F. Mott (British) for helping develop semiconductor devices.

1978 Pyotr Kapitsa (Soviet) for his research in low-temperature physics, and Arno Penzias and Robert Wilson (American) for their discovery and study of cosmic microwave background radiation.

1979 Sheldon L. Glashow and Steven Weinberg (American) and Abdus Salam (Pakistani) for developing a principle that unifies the weak nuclear force and the force of electromagnetism.

1980 James W. Cronin and Val L. Fitch (American) for their research on subatomic particles revealing that the fundamental laws of symmetry in nature could be violated.

1981 Nicolaas Bloembergen and Arthur L. Schawlow (American) for their contribution to the development of laser spectroscopy, and Kai Siegbahn (Swedish) for his contribution to the development of high-resolution electron spectroscopy.

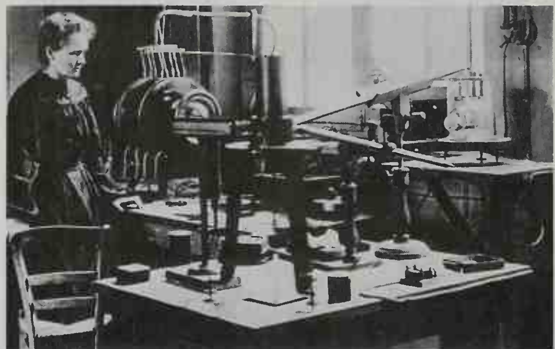
1982 Kenneth G. Wilson (American) for his method of analyzing the behavior of matter when it changes form—for example, from water to steam.

1983 *Subrahmanyan Chandrasekhar and William A. Fowler (American) for work on the evolution and death of stars.

1984 Carlo Rubbia (Italian) and Simon van der Meer (Dutch) for contributions to the discovery of two subatomic particles—the *W particle* and the *Z particle*.

1985 Klaus von Klitzing (West German) for developing a precise way of measuring electrical resistance.

1986 Ernst Ruska (West German) for his invention of the electron microscope and Gerd Binning (West German) and Heinrich Rohrer (Swiss) for their invention of the scanning tunneling microscope.



1987 J. Georg Bednorz (West German) and K. Alex Müller (Swiss) for their discovery of superconductivity in a ceramic material.

1988 Leon M. Lederman, Melvin Schwartz, and Jack Steinberger (American) for their work on subatomic particles called *neutrinos*.

1989 Hans G. Dehmelt (American) and Wolfgang Paul (German) for isolating and measuring single atoms, and Norman F. Ramsey (American) for work that led to the atomic clock.

*Has a biography in *World Book*.

Nobel Prizes in physics (continued)

Bettmann Archive

Marie Curie shared the 1903 physics prize with her husband, Pierre, for their study of radiation and with Antoine Henri Becquerel for his discovery of natural radioactivity. Marie Curie also won the 1911 chemistry prize for her discovery of and work with the elements radium and polonium.

1990 Jerome Friedman and *Henry Kendall (American) and Richard Taylor (Canadian) for experiments that proved the existence of subatomic particles called *quarks.*
1991 Pierre-Gilles de Gennes (French) for his analyses of alignments and other orderly arrangements of molecules in certain substances.
1992 Georges Charpak (French) for the invention of devices that detect subatomic particles in particle accelerators.
1993 Russell A. Hulse and Joseph H. Taylor, Jr. (American), for their discovery of extremely dense pairs of stars called *binary pulsars.*
1994 Clifford G. Shull (American) and Bertram N. Brockhouse (Canadian) for using neutrons to probe the atomic structure of solids.
1995 Martin Perl (American) for research on a subatomic particle called the *tau,* and Frederick Reines (American) for his discovery of a subatomic particle called the *neutrino.*
1996 David M. Lee, Robert C. Richardson, and Douglas D. Osheroff (American) for discovering that a type of helium called *helium-3* becomes a *superfluid,* a rare form of matter, at an extremely low temperature.
1997 Steven Chu and William D. Phillips (Americans) and Claude Cohen-Tannoudji (French) for developing a way to trap atoms with laser light.
1998 Robert B. Laughlin (American), Horst L. Störmer (German-born American), and Daniel C. Tsui (Chinese-born American) for discovering a magnetic phenomenon called the *fractional quantum Hall effect.*
1999 Gerardus 't Hooft and Martinus J. G. Veltman (Dutch) for developing calculation methods used with the *electroweak theory,* a description of the behavior of subatomic particles.
2000 Zhores I. Alferov (Russian) and Herbert Kroemer (German-born American) for developing certain layered structures that are used in electronic devices, and *Jack Kilby (American) for his part in the invention of the integrated circuit.
2001 Eric A. Cornell (American), Wolfgang Ketterle (German), and Carl E. Wieman (American) for the discovery and study of a state of matter known as a *Bose-Einstein condensate.*

Nobel Prizes in chemistry

1901 Jacobus Henricus Van't Hoff (Dutch) for discovering laws of chemical dynamics and osmotic pressure.
1902 Emil Fischer (German) for synthesizing sugars, purine derivatives, and peptides.
1903 Svante August Arrhenius (Swedish) for his dissociation theory of ionization in electrolytes.
1904 *Sir William Ramsay (British) for discovering helium, neon, xenon, and krypton, and determining their place in the periodic system.
1905 Adolph von Baeyer (German) for his work on dyes and organic compounds, and for synthesizing indigo and arsenicals.
1906 Henri Moissan (French) for preparing pure fluorine and developing the electric furnace.
1907 Eduard Buchner (German) for his biochemical researches and for discovering cell-less fermentation.
1908 *Ernest Rutherford (New Zealand-born) for discovering that radioactive elements change into other elements.
1909 *Wilhelm Ostwald (German) for his work on catalysis, chemical equilibrium, and the rate of chemical reactions.
1910 Otto Wallach (German) for work on alicyclic substances.
1911 *Marie Curie (French) for discovering radium and polonium, isolating radium, and studying radium's compounds.
1912 François A. V. Grignard (French) for discovering the Grignard reagent to synthesize organic compounds, and Paul Sabatier (French) for his method of using nickel as a hydrogenation catalyst.
1913 Alfred Werner (Swiss) for his coordination theory on the arrangement of atoms.
1914 Theodore W. Richards (American) for determining the atomic weights of many elements.
1915 Richard Willstätter (German) for his research on chlorophyll and other coloring matter in plants.
1916-1917 No award
1918 Fritz Haber (German) for the Haber-Bosch process of synthesizing ammonia from nitrogen and hydrogen.
1919 No award
1920 Walther Nernst (German) for his discoveries concerning heat changes in chemical reactions.
1921 *Frederick Soddy (British) for studying radioactive substances and isotopes.
1922 Francis W. Aston (British) for finding many isotopes by means of the mass spectrograph and for discovering the whole number rule on the structure and weight of atoms.
1923 Fritz Pregl (Austrian) for inventing a method of microanalyzing organic substances.
1924 No award
1925 Richard Zsigmondy (Austrian) for his method of studying colloids.
1926 Theodor Svedberg (Swedish) for his work on dispersions and on colloid chemistry.
1927 Heinrich O. Wieland (German) for studying gall acids and related substances.
1928 Adolf Windaus (German) for studying sterols and their connection with vitamins.
1929 Sir Arthur Harden (British) and Hans August Simon von Euler-Chelpin (German) for their research on sugar fermentation and enzymes.
1930 Hans Fischer (German) for studying the coloring matter of blood and leaves and synthesizing hemin.
1931 Carl Bosch and Friedrich Bergius (German) for inventing high-pressure methods of manufacturing ammonia and liquefying coal.
1932 Irving Langmuir (American) for his discoveries about molecular films absorbed on surfaces.
1933 No award
1934 *Harold Clayton Urey (American) for discovering deuterium (heavy hydrogen).
1935 Frédéric and *Irène Joliot-Curie (French) for synthesizing new radioactive elements.
1936 Peter J. W. Debye (Dutch) for his studies on dipole moments, the diffraction of electrons, and X rays in gases.
1937 Sir Walter N. Haworth (British) for his research on carbohydrates and vitamin C, and Paul Karrer (Swiss) for studying carotenoids, flavins, and vitamins A and B_2.
1938 Richard Kuhn (German) for his work on carotenoids and vitamins (declined).

*Has a biography in *World Book.*

obel Prizes in chemistry (continued)

39 Adolph Butenandt (German) for studying sex hormones (declined), and Leopold Ružička (Swiss) for his work on polymethylenes.

40-1942 No award

43 Georg von Hevesy (Hungarian) for using isotopes as indicators in chemistry.

44 *Otto Hahn (German) for his discoveries in fission.

45 Artturi Virtanen (Finnish) for inventing new methods in agricultural biochemistry.

46 James B. Sumner (American) for discovering that enzymes can be crystallized, and Wendell M. Stanley and *John H. Northrop (American) for preparing pure enzymes and virus proteins.

47 Sir Robert Robinson (British) for his research on biologically significant plant substances.

48 Arne Tiselius (Swedish) for his discoveries on the nature of the serum proteins.

49 William Francis Giauque (American) for studying reactions to extreme cold.

50 Otto Diels and Kurt Alder (German) for developing a method of synthesizing organic compounds of the diene group.

51 Edwin M. McMillan and *Glenn T. Seaborg (American) for their work in discovering plutonium and other elements.

52 Archer J. P. Martin and Richard Synge (British) for developing the partition chromatography process, a method of separating compounds.

53 Hermann Staudinger (German) for discovering a way to synthesize fiber.

54 *Linus Pauling (American) for his work on the forces that hold matter together.

55 Vincent Du Vigneaud (American) for discovering a process for making synthetic hormones.

56 Sir Cyril Hinshelwood (British) and Nikolai N. Semenov (Soviet) for their work on chemical chain reactions.

57 Lord Todd (British) for his work on the protein composition of cells.

58 *Frederick Sanger (British) for discovering the structure of the insulin molecule.

59 Jaroslav Heyrovský (Czech) for developing the polarographic method of analysis.

60 *Willard F. Libby (American) for developing a method of radiocarbon dating.

61 Melvin Calvin (American) for his research on photosynthesis.

62 *Sir John Cowdery Kendrew and *Max Ferdinand Perutz (British) for their studies on globular proteins.

63 Giulio Natta (Italian) for his contributions to the understanding of *polymers,* and Karl Ziegler (German) for his production of *organometallic compounds.* Their work resulted in improved plastics.

64 *Dorothy C. Hodgkin (British) for X-ray studies of compounds such as vitamin B_{12} and penicillin.

65 Robert Burns Woodward (American) for his contributions to organic synthesis.

66 *Robert S. Mulliken (American) for developing the *molecular-orbital* theory of chemical structure.

67 Manfred Eigen (German) and Ronald G. W. Norrish and George Porter (British) for developing techniques to measure rapid chemical reactions.

68 Lars Onsager (American) for developing the theory of reciprocal relations of various thermodynamic activity.

69 Derek H. R. Barton (British) and Odd Hassel (Norwegian) for studies relating chemical reactions with the three-dimensional shape of molecules.

70 Luis Federico Leloir (Argentine) for his discovery of chemical compounds that affect the storage of chemical energy in living things.

71 Gerhard Herzberg (Canadian) for his research in the structure of molecules, particularly for his work on molecular fragments called *free radicals.*

72 Christian B. Anfinsen, Stanford Moore, and William H. Stein (American) for fundamental contributions to the chemistry of *enzymes,* basic substances of living things.

1973 Geoffrey Wilkinson (British) and Ernst Fischer (German) for their work on *organometallic compounds,* which consist of organic compounds and metal atoms.

1974 Paul John Flory (American) for work in polymer chemistry.

1975 John Warcup Cornforth (Australian-born) and Vladimir Prelog (Swiss) for their work on the chemical synthesis of important organic compounds.

1976 William N. Lipscomb, Jr. (American), for his studies on the structure and bonding mechanisms of *boranes,* complex compounds of boron and hydrogen.

1977 Ilya Prigogine (Belgian) for his contributions to non-equilibrium thermodynamics.

1978 Peter Mitchell (British) for his studies of cellular energy transfer.

1979 Herbert C. Brown (American) and Georg Wittig (German) for developing compounds capable of producing chemical bonds useful in the manufacture of drugs and in other industrial processes.

1980 Paul Berg and Walter Gilbert (American) and *Frederick Sanger (British) for their studies of the chemical structure of nucleic acids.

1981 Kenichi Fukui (Japanese) and Roald Hoffmann (American) for applying the theories of quantum mechanics to predict the course of chemical reactions.

1982 Aaron Klug (British) for his work with the electron microscope and for his research into the structure of nucleic acid-protein complexes.

1983 Henry Taube (American) for his research on the transfer of electrons between molecules in chemical reactions.

1984 R. Bruce Merrifield (American) for developing a rapid, automated method for making *peptides,* the building blocks of proteins.

1985 Herbert A. Hauptman and Jerome Karle (American) for developing techniques for quickly determining the chemical structure of molecules vital to life.

1986 Dudley R. Herschbach and Yuan T. Lee (American) and John C. Polanyi (Canadian) for their pioneering research on basic chemical reactions.

1987 Jean-Marie Lehn (French) and Donald J. Cram and Charles J. Pedersen (American) for their development of, and work with, artificial molecules that function like natural organic molecules.

1988 Johann Deisenhofer, Robert Huber, and Hartmut Michel (West German) for revealing the structure of proteins that are essential to photosynthesis.

1989 Sidney Altman and Thomas R. Cech (American) for their discovery that ribonucleic acid (RNA) is able to assist chemical reactions in cells.

1990 Elias James Corey (American) for developing techniques for artificially duplicating such natural substances as compounds for use as drugs.

1991 Richard R. Ernst (Swiss) for improvements in the use of nuclear magnetic resonance (NMR) to analyze chemicals.

1992 Rudolph A. Marcus (American) for analyzing the transfer of electrons between molecules.

1993 Kary B. Mullis (American) for his method of copying genetic material, and Michael Smith (Canadian) for his method of altering DNA molecules.

1994 George A. Olah (Hungarian-born) for discovering ways to break up hydrocarbon molecules and stabilize the resulting parts.

1995 Mario Molina and F. Sherwood Rowland (American) and Paul Crutzen (Dutch) for work leading to the discovery of a "hole" in the earth's protective layer of ozone.

1996 Richard E. Smalley and Robert F. Curl, Jr. (American), and Sir Harold W. Kroto (British) for discovering carbon molecules called *fullerenes.*

1997 Paul D. Boyer (American), Jens C. Skou (Danish), and John E. Walker (British) for discoveries about adenosine triphosphate (ATP), a molecule living things use to store energy.

1998 Walter Kohn (Austrian-born American) for his mathematical analysis of chemical bonds, and John A. Pople (British)

*Has a biography in *World Book.*

Nobel Prizes in chemistry (continued)

for his computer techniques for determining the structure of molecules.

1999 Ahmed H. Zewail (Egyptian-born American) for his development of experimental techniques for detecting the individual steps of chemical reactions.

2000 Alan J. Heeger (American), Alan G. MacDiarmid (New Zealand-born American), and Hideki Shirakawa (Japanese) for the discovery and development of polymers that can conduct electric current.

2001 William S. Knowles (American), Ryoji Noyori (Japanese), and K. Barry Sharpless (American) for their development of molecules that are used to produce a number of drugs.

Nobel Prizes in physiology or medicine

1901 Emil von Behring (German) for discovering the diphtheria antitoxin.

1902 Sir Ronald Ross (British) for working on malaria and discovering how malaria is transmitted.

1903 Niels Ryberg Finsen (Danish) for treating diseases, especially *lupus vulgaris,* with concentrated light rays.

1904 *Ivan Petrovich Pavlov (Russian) for his work on the physiology of digestion.

1905 *Robert Koch (German) for working on tuberculosis and discovering the tubercule bacillus and tuberculin.

1906 *Camillo Golgi (Italian) and Santiago Ramon y Cajal (Spanish) for their studies of nerve tissue.

1907 *Charles Louis Alphonse Laveran (French) for studying diseases caused by protozoans.

1908 *Paul Ehrlich (German) and *Elie Metchnikoff (Russian) for their work on immunity.

1909 Emil Theodor Kocher (Swiss) for his work on the physiology, pathology, and surgery of the thyroid gland.

1910 Albrecht Kossel (German) for studying cell chemistry, proteins, and nucleic substances.

1911 Allvar Gullstrand (Swedish) for his work on dioptrics, the refraction of light through the eye.

1912 Alexis Carrel (French) for suturing blood vessels and grafting vessels and organs.

1913 Charles Robert Richet (French) for studying allergies caused by foreign substances, as in hay fever.

1914 Robert Bárány (Austrian) for work on function and diseases of equilibrium organs in the inner ear.

1915-1918 No award

1919 Jules Bordet (Belgian) for discoveries on immunity.

1920 August Krogh (Danish) for discovering the system of action of blood capillaries.

1921 No award

1922 Archibald V. Hill (British) for his discovery on heat production in the muscles, and Otto Meyerhof (German) for his theory on the production of lactic acid in the muscles.

1923 *Sir Frederick G. Banting (Canadian) and John J. R. Macleod (Scottish) for discovering insulin.

1924 *Willem Einthoven (Dutch) for his discovery of the way in which electrocardiography works.

1925 No award

1926 Johannes Fibiger (Danish) for discovering a parasite that causes cancer.

*Has a biography in *World Book.*

Bettmann Archive

Ivan Petrovich Pavlov, a Russian physiologist, won the 1904 prize in physiology or medicine. Pavlov and his staff experimented with dogs to learn how nerves affect the process of digestion.

1927 Julius Wagner von Jauregg (Austrian) for discovering the fever treatment for paralysis.

1928 Charles Nicolle (French) for his work on typhus.

1929 Christiaan Eijkman (Dutch) for discovering vitamins that prevent beriberi, and Sir Frederick Hopkins (British) for finding vitamins that aid growth.

1930 *Karl Landsteiner (American) for discovering the four main human blood types.

1931 Otto H. Warburg (German) for discovering that enzymes aid in respiration by tissues.

1932 Edgar D. Adrian and Sir Charles S. Sherrington (British) for their discoveries on the function of neurons.

1933 *Thomas H. Morgan (American) for studying the function o chromosomes in heredity.

1934 George R. Minot, William P. Murphy, and George H. Whipple (American) for their discoveries on liver treatment for anemia.

1935 Hans Spemann (German) for discovering the organizer-effect in the growth of an embryo.

1936 Sir Henry H. Dale (British) and Otto Loewi (German-born) for their discoveries on the chemical transmission of nerv impulses.

1937 *Albert Szent-Györgyi (Hungarian) for his discoveries in connection with oxidation in tissues, vitamin C, and fumaric acid.

1938 Corneille Heymans (Belgian) for his discoveries concerning the regulation of respiration.

1939 *Gerhard Domagk (German) for discovering Prontosil, the first sulfa drug (declined).

1940-1942 No award

1943 Henrik Dam (Danish) for discovering vitamin K, and Edward Doisy (American) for synthesizing it.

1944 Joseph Erlanger and Herbert Gasser (American) for their work on single nerve fibers.

1945 *Alexander Fleming (British) for discovering penicillin, and *Howard W. Florey and *Ernst B. Chain (British) for developing its use as an antibiotic.

1946 Hermann Joseph Muller (American) for discovering that X rays can produce mutations.

1947 Carl F. and Gerty Cori (American) for their work on insulin and Bernardo Houssay (Argentine) for studying the pancreas and the pituitary gland.

1948 Paul H. Müller (Swiss) for discovering the insect-killing properties of DDT.

1949 Walter R. Hess (Swiss) for discovering how certain parts the brain control organs of the body, and Antônio Egas Moniz (Portuguese) for originating prefrontal lobotomy.

1950 Philip S. Hench, Edward C. Kendall (American), and Tadei Reichstein (Swiss) for discoveries on cortisone and ACTH.

1951 Max Theiler (South African who worked in the United States) for developing the yellow fever vaccine 17-D.

1952 *Selman A. Waksman (American) for his work in the discovery of streptomycin.

1953 Fritz Albert Lipmann (American) and *Hans Adolf Krebs (British) for discoveries in biosynthesis and metabolism.

1954 *John F. Enders, Thomas H. Weller, and Frederick C. Robbins (American) for discovering a simple method of growing polio virus in test tubes.

1955 Hugo Theorell (Swedish) for his discoveries on the natu and action of oxidation enzymes.

1956 André F. Cournand, Dickinson W. Richards (American), and Werner Forssmann (German) for using a catheter tc chart the interior of the heart.

1957 Daniel Bovet (Italian) for discovering antihistamines.

Nobel Prizes in physiology or medicine (continued)

1958 *George Wells Beadle and Edward Lawrie Tatum (American) for their work in biochemical genetics, and *Joshua Lederberg (American) for his studies of genetics in bacteria.

1959 Severo Ochoa and Arthur Kornberg (American) for producing nucleic acid by artificial means.

1960 *Sir Macfarlane Burnet (Australian) and Peter B. Medawar (British) for research in transplanting human organs.

1961 Georg von Békésy (American) for demonstrating how the ear distinguishes among various sounds.

1962 *James D. Watson (American) and *Francis H. C. Crick and *Maurice H. F. Wilkins (British) for work on nucleic acid.

1963 Sir John Carew Eccles (Australian) for his research on the transmission of nerve impulses, and Alan Lloyd Hodgkin (British) and Andrew Fielding Huxley (British) for their description of the behavior of nerve impulses.

1964 *Konrad E. Bloch (American) and *Feodor Lynen (German) for their work on cholesterol and fatty acid metabolism.

1965 François Jacob, André Lwoff, and Jacques Monod (French) for their discoveries concerning genetic control of enzyme and virus synthesis.

1966 *Francis Peyton Rous (American) for discovering a cancer-producing virus, and Charles B. Huggins (American) for discovering uses of hormones in treating cancer.

1967 Ragnar Granit (Swedish) and H. Keffer Hartline and *George Wald (American) for their findings about chemical and physiological processes that take place in the eye.

1968 Robert W. Holley, H. Gobind Khorana, and Marshall W. Nirenberg (American) for explaining how genes determine the function of cells.

1969 Max Delbrück, Alfred Hershey, and Salvador Luria (American) for their work with *bacteriophages* (viruses that attack bacteria).

1970 Julius Axelrod (American), Bernard Katz (British), and Ulf Svante von Euler (Swedish) for their discoveries of the role played by certain chemicals in the transmission of nerve impulses.

1971 Earl W. Sutherland, Jr. (American), for his discovery of the ways hormones act, including the discovery of cyclic AMP, a chemical that influences the actions of hormones on body processes.

1972 Gerald M. Edelman (American) and Rodney R. Porter (British) for their discovery of the chemical structure of antibodies.

1973 *Nikolaas Tinbergen (Dutch-born) and *Konrad Z. Lorenz and *Karl von Frisch (Austrian) for their studies on animal behavior.

1974 Christian de Duve (Belgian) and Albert Claude and George E. Palade (American) for their pioneer work in cell biology.

1975 David Baltimore, Renato Dulbecco, and Howard M. Temin (American) for their research on how certain viruses affect the genes of cancer cells.

1976 Baruch S. Blumberg and D. Carleton Gajdusek (American) for their discoveries concerning the origin and spread of infectious diseases.

1977 Roger Guillemin, Andrew Schally, and Rosalyn Yalow (American) for their research concerning the role of hormones in the chemistry of the body.

1978 Werner Arber (Swiss) and Daniel Nathans and Hamilton O. Smith (American) for discoveries in molecular genetics.

1979 Allan MacLeod Cormack (American) and Godfrey N. Hounsfield (British) for their contributions to development of the computerized tomographic (CT) scanner.

1980 Baruj Benacerraf and George D. Snell (American) and Jean Dausset (French) for their discoveries concerning the genetic regulation of the body's immune system.

1981 Roger W. Sperry and David H. Hubel (American) and Torsten N. Wiesel (Swedish) for their research on the organization and functioning of the brain.

1982 Sune K. Bergstrom and Bengt I. Samuelsson (Swedish) and John R. Vane (British) for their discoveries regarding prostaglandins and related substances.

1983 *Barbara McClintock (American) for her discovery that genes sometimes behave unexpectedly inside cells.

1984 Niels K. Jerne (British-born), Georges J. F. Köhler (German), and Cesar Milstein (Argentine) for their discoveries in immunology.

1985 Michael S. Brown and Joseph L. Goldstein (American) for explaining how high cholesterol causes heart disease.

1986 Stanley Cohen (American) and Rita Levi-Montalcini (Italian-born) for their research on cell and organ growth.

1987 Susumu Tonegawa (Japanese) for his discoveries on how genes change to produce antibodies against specific disease agents.

1988 *Gertrude B. Elion and George H. Hitchings (American) and Sir James Black (British) for their discoveries of important principles for drug treatment.

1989 J. Michael Bishop and Harold E. Varmus (American) for their research on cancer-causing genes called *oncogenes.*

1990 Joseph E. Murray and E. Donnall Thomas (American) for their work in transplanting human organs and bone marrow.

1991 Erwin Neher and Bert Sakmann (German) for discovering how cells communicate with one another.

1992 Edmond Fischer and Edwin Krebs (American) for discovering a chemical process in cells that is linked to cancer and to rejection of transplanted organs.

1993 Richard J. Roberts (British-born) and Phillip A. Sharp (American) for their discoveries regarding the structure and function of genes.

1994 Alfred G. Gilman and Martin Rodbell (American) for their research into signaling mechanisms in cells.

1995 Edward B. Lewis and Eric Wieschaus (American) and Christiane Nüsslein-Volhard (German) for their studies of how genes control early embryo development.

1996 Peter C. Doherty (Australian) and Rolf M. Zinkernagel (Swiss) for discovering the signals that alert white blood cells to kill virus-infected cells.

1997 Stanley B. Prusiner (American) for his discovery of prions, a new type of infectious particle that appears to consist only of protein.

1998 Robert F. Furchgott, Louis J. Ignarro, and Ferid Murad (American) for their discovery that the gas nitric oxide acts as an important signal molecule in the heart and blood vessels.

1999 Günter Blobel (German-born) for his discoveries on the movement of proteins within the cells of living organisms.

2000 Arvid Carlsson (Swedish) and Paul Greengard and Eric Kandel (American) for their research on the transmission of impulses between nerve cells.

2001 Leland H. Hartwell (American) and Timothy Hunt and Sir Paul Nurse (British) for their discoveries regarding genetic control of cell division in living organisms.

Nobel Prizes in literature

1901 *Sully Prudhomme (French) for his poems.

1902 Theodor Mommsen (German) for his historical narratives, particularly his history of Rome.

1903 *Bjørnstjerne Bjørnson (Norwegian) for his novels, poems, and dramas.

1904 *Frédéric Mistral (French) for his poems, and José Echegaray y Eizaguirre (Spanish) for his dramas.

1905 *Henryk Sienkiewicz (Polish) for his novels.

1906 *Giosuè Carducci (Italian) for his poems.

1907 *Rudyard Kipling (British) for his stories, novels, and poems.

1908 Rudolf Eucken (German) for his philosophic writings.

1909 *Selma Lagerlöf (Swedish) for her novels and poems.

*Has a biography in *World Book.*

Nobel Prizes in literature (continued)

1910 Paul von Heyse (German) for his poems, novels, and dramas.
1911 *Maurice Maeterlinck (Belgian) for his dramas.
1912 *Gerhart Hauptmann (German) for his dramas.
1913 *Rabindranath Tagore (Indian) for his poems.
1914 No award
1915 *Romain Rolland (French) for his novels.
1916 Verner von Heidenstam (Swedish) for his poems.
1917 Karl Gjellerup (Danish) for his poems and novels, and Henrik Pontoppidan (Danish) for his novels and short stories.
1918 No award
1919 Carl Spitteler (Swiss) for his epics, stories, and essays.
1920 *Knut Hamsun (Norwegian) for his novels.
1921 *Anatole France (French) for his novels, short stories, and essays.
1922 *Jacinto Benavente (Spanish) for his dramas.
1923 *William Butler Yeats (Irish) for his poems.
1924 Wladyslaw S. Reymont (Polish) for his novels.
1925 *George Bernard Shaw (Irish-born) for his plays.
1926 Grazia Deledda (Italian) for her novels.
1927 *Henri Bergson (French) for his philosophic writings.
1928 *Sigrid Undset (Norwegian) for her novels.
1929 *Thomas Mann (German) principally for his novel *Buddenbrooks.*
1930 *Sinclair Lewis (American) for his novels.
1931 Erik Axel Karlfeldt (Swedish) for his lyric poetry.
1932 *John Galsworthy (British) for his novels, plays, and short stories.
1933 *Ivan Bunin (Soviet) for his novels, short stories, and poems.
1934 *Luigi Pirandello (Italian) for his dramas.
1935 No award
1936 *Eugene O'Neill (American) for his dramas.
1937 Roger Martin du Gard (French) for his novels.
1938 *Pearl S. Buck (American) for her novels.
1939 Frans Eemil Sillanpää (Finnish) for his novels.
1940-1943 No award
1944 Johannes V. Jensen (Danish) for his poems and novels.
1945 *Gabriela Mistral (Chilean) for her poems.
1946 *Hermann Hesse (German) for his novels, poems, and essays.
1947 *André Gide (French) for his novels.
1948 *T. S. Eliot (British) for his poems, essays, and plays.
1949 *William Faulkner (American) for his novels. (Award delayed until 1950.)

*Has a biography in *World Book.*

United Press Int.

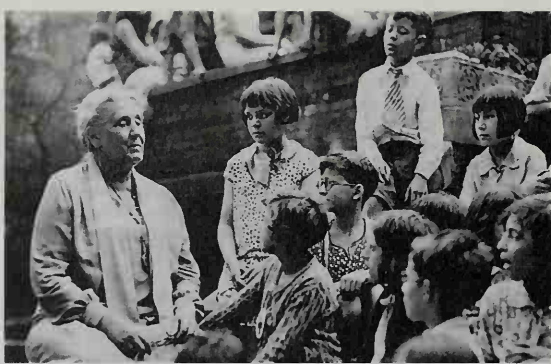
Sinclair Lewis became the first American to win the literature prize. He received the award in 1930 for his satirical novels.

1950 *Bertrand Russell (British) for his philosophic writings.
1951 *Pär Fabian Lagerkvist (Swedish) for his novels, particularly *Barabbas.*
1952 *François Mauriac (French) for his novels, essays, and poems.
1953 *Sir Winston Churchill (British) for his essays, speeches, and historical writings.
1954 *Ernest Hemingway (American) for his novels and short stories.
1955 Halldór K. Laxness (Icelandic) for his novels.
1956 *Juan Ramón Jiménez (Spanish) for his poems.
1957 *Albert Camus (French) for his novels.
1958 *Boris Pasternak (Soviet) for his novels, especially *Dr. Zhivago* (declined).
1959 *Salvatore Quasimodo (Italian) for his lyric poems.
1960 *Saint-John Perse (French) for his poems.
1961 Ivo Andrić (Yugoslav) for his novels, especially *The Bridge on the Drina.*
1962 *John Steinbeck (American) for his novels, especially *The Winter of Our Discontent.*
1963 George Seferis (Greek) for his lyric poetry.
1964 *Jean-Paul Sartre (French) for his philosophical works (declined).
1965 *Mikhail Sholokhov (Soviet) for his novels.
1966 *Shmuel Yosef Agnon (Israeli) for his stories of Eastern European Jewish life, and *Nelly Sachs (German-born) for her poetry and plays about the Jewish people.
1967 *Miguel Angel Asturias (Guatemalan) for his writings rooted in national individuality and Indian traditions.
1968 Yasunari Kawabata (Japanese) for his novels.
1969 *Samuel B. Beckett (Irish-born) for his novels and plays.
1970 *Alexander Solzhenitsyn (Soviet) for his novels.
1971 *Pablo Neruda (Chilean) for his poems.
1972 *Heinrich Böll (German) for his novels, short stories, and plays.
1973 *Patrick White (Australian) for his novels.
1974 Eyvind Johnson (Swedish) for his novels and short stories, and Harry Edmund Martinson (Swedish) for his essays, plays, novels, and poems.
1975 *Eugenio Montale (Italian) for his poems.
1976 *Saul Bellow (American) for his novels.
1977 *Vicente Aleixandre (Spanish) for his poems.
1978 *Isaac Bashevis Singer (Polish-born) for his novels and short stories.
1979 Odysseus Elytis (Greek) for his poems.
1980 Czesław Milosz (Polish-born) for his poems.
1981 Elias Canetti (Bulgarian-born) for his fiction and nonfiction.
1982 *Gabriel García Márquez (Colombian) for his novels and short stories.
1983 *William Golding (British) for his novels.
1984 Jaroslav Seifert (Czech) for his poems.
1985 Claude Simon (French) for his novels.
1986 *Wole Soyinka (Nigerian) for his plays, poems, and novels.
1987 *Joseph Brodsky (Soviet-born) for his poems.
1988 *Naguib Mahfouz (Egyptian) for his novels and short stories.
1989 Camilo José Cela (Spanish) for his novels.
1990 *Octavio Paz (Mexican) for his poems and essays.
1991 *Nadine Gordimer (South African) for her novels and short stories.
1992 *Derek Walcott (St. Lucian-born) for his poetry.
1993 *Toni Morrison (American) for her novels.
1994 Kenzaburo Oe (Japanese) for his novels.
1995 *Seamus Heaney (Irish) for his poetry.
1996 *Wislawa Szymborska (Poland) for her poetry.
1997 Dario Fo (Italian) for his plays.
1998 José Saramago (Portugal) for his novels.
1999 *Günter Grass (German) for his novels.
2000 Gao Xingjian (Chinese) for his plays, novels, and essays.
2001 *V. S. Naipaul (West Indian-born) for his novels.

Nobel Peace Prizes

1901 *Jean Henri Dunant (Swiss) for founding the Red Cross and originating the Geneva Convention, and Frédéric Passy (French) for founding a French peace society.
1902 Élie Ducommun (Swiss) for his work as honorary secretary of the International Peace Bureau, and Charles Albert Gobat (Swiss) for his work as administrator of the Inter-Parliamentary Union.
1903 Sir William Cremer (British) for his activities as founder and secretary of the International Arbitration League.
1904 The Institute of International Law for its studies on the laws of neutrality and other phases of international law.
1905 Baroness Bertha von Suttner (Austrian) for promoting pacifism and founding an Austrian peace society.
1906 *Theodore Roosevelt (American) for negotiating peace in the Russo-Japanese War.
1907 Ernesto T. Moneta (Italian) for his work as president of the Lombard League for Peace, and Louis Renault (French) for organizing international conferences and representing France at two peace conferences.
1908 Klas Pontus Arnoldson (Swedish) for founding the Swedish Society for Arbitration and Peace, and Fredrik Bajer (Danish) for his work on the International Peace Bureau.
1909 Auguste M. F. Beernaert (Belgian) for his work on the Permanent Court of Arbitration, and Paul d'Estournelles (French) for founding and directing the French Parliamentary Arbitration Committee and League of International Conciliation.
1910 The International Peace Bureau for promoting international arbitration and organizing peace conferences.
1911 Tobias M. C. Asser (Dutch) for organizing conferences on international law, and Alfred H. Fried (Austrian) for his writings on peace as editor of *Die Friedenswarte*.
1912 *Elihu Root (American) for settling the problem of Japanese immigration to California and organizing the Central American Peace Conference.
1913 Henri Lafontaine (Belgian) for his work as president of the International Peace Bureau.
1914-1916 No award
1917 The International Red Cross for doing relief work during World War I.
1918 No award
1919 *Woodrow Wilson (American) for attempting a just settlement of World War I and advocating the League of Nations. (Award delayed until 1920.)
1920 Léon Bourgeois (French) for his contribution as president of the Council of the League of Nations.
1921 Karl Hjalmar Branting (Swedish) for promoting social reforms in Sweden and serving as the Swedish delegate to the League of Nations, and Christian Louis Lange (Norwegian) for his contribution as secretary-general of the Inter-Parliamentary Union.
1922 *Fridtjof Nansen (Norwegian) for doing relief work among Russian prisoners of war and in famine areas in Russia.
1923-1924 No award
1925 Sir Austen Chamberlain (British) for helping work out the Locarno Peace Pact, and *Charles G. Dawes (American) for originating a plan for payment of German reparations.
1926 *Aristide Briand (French) for his part in forming the Locarno Peace Pact, and Gustav Stresemann (German) for persuading Germany to accept plans for reparations.
1927 Ferdinand Buisson (French) for his contribution as president of the League of Human Rights, and Ludwig Quidde (German) for his writings on peace and his work in international peace congresses.
1928 No award
1929 Frank Billings Kellogg (American) for negotiating the Kellogg-Briand Peace Pact.
1930 Nathan Söderblom (Swedish) for writing on and working for peace.
1931 *Jane Addams (American) for her work with the Women's International League for Peace and Freedom, and *Nicholas M. Butler (American) for his work with the Carnegie Endowment for International Peace.
1932 No award
1933 Sir Norman Angell (British) for his work with the Royal Institute of International Affairs, the League of Nations, and the National Peace Council.
1934 Arthur Henderson (British) for his contribution as president of the World Disarmament Conference.
1935 Carl von Ossietzky (German) for promoting world disarmament. (Award delayed until 1936.)
1936 Carlos Saavedra Lamas (Argentine) for negotiating a peace settlement between Bolivia and Paraguay in the Chaco War.
1937 Edgar Algernon Robert Gascoyne Cecil (British) for promoting the League of Nations and working with peace movements.
1938 The Nansen International Office for Refugees for directing relief work among refugees.
1939-1943 No award
1944 The International Red Cross for doing relief work during World War II.
1945 *Cordell Hull (American) for his peace efforts as secretary of state.
1946 John R. Mott (American) for his YMCA work and for aiding displaced persons, and *Emily Greene Balch (American) for her work with the Women's International League for Peace and Freedom.
1947 The Friends Service Council and the American Friends Service Committee for humanitarian work.
1948 No award
1949 John Boyd Orr (British) for directing the United Nations Food and Agriculture Organization.
1950 *Ralph J. Bunche (American) for his work as UN mediator in Palestine in 1948 and 1949.
1951 Léon Jouhaux (French) for his work helping to organize national and international labor unions.

*Has a biography in *World Book*.



Bettmann Archive

Elihu Root won the Nobel Peace Prize in 1912. As U.S. secretary of state, Root made important contributions to world peace.

Bettmann Archive

Woodrow Wilson won the 1919 peace prize, the second awarded to a U.S. president. Theodore Roosevelt won in 1906.

Hull House Association

Jane Addams, an American social worker, shared the 1931 peace prize for her work with an international peace group.

United Press Int.

Albert Schweitzer won the 1952 Nobel Peace Prize. He devoted most of his life to humanitarian work in Africa.

Nobel Peace Prizes (continued)

1952 *Albert Schweitzer (German-born) for his humanitarian work in Africa. (Award delayed until 1953.)
1953 *George C. Marshall (American) for promoting peace through the European Recovery Program.
1954 Office of the United Nations High Commissioner for Refugees for providing protection for millions of refugees and seeking permanent solutions to their problems.
1955-1956 No award
1957 *Lester B. Pearson (Canadian) for organizing a United Nations force in Egypt.
1958 Dominique Georges Pire (Belgian) for his work in resettling displaced persons.
1959 Philip Noel-Baker (British) for his work in promoting peace and disarmament.
1960 *Albert John Luthuli (African) for his peaceful campaign against racial restrictions in South Africa.
1961 *Dag Hammarskjöld (Swedish) for his efforts to bring peace to the Congo (awarded posthumously).
1962 *Linus Pauling (American) for efforts to ban nuclear weapons and nuclear testing.
1963 International Committee of the Red Cross and League of Red Cross Societies for humanitarian work.
1964 *Martin Luther King, Jr. (American), for leading the black struggle for equality in the United States through nonviolent means.
1965 United Nations Children's Fund for its aid to children.
1966-1967 No award
1968 René Cassin (French) for promoting human rights.
1969 *International Labour Organization (ILO) for its efforts to improve working conditions.
1970 *Norman E. Borlaug (American) for his role in developing high-yield grains that increased food production in developing countries.
1971 *Willy Brandt (German) for his efforts to improve relations between Communist and non-Communist nations.
1972 No award
1973 *Henry A. Kissinger (American) and Le Duc Tho (North Vietnamese) for their work in negotiating the Vietnam War cease-fire agreement (Le Duc Tho declined).
1974 Sean MacBride (Irish) for working to guarantee human rights through international law, and Eisaku Sato (Japanese) for his efforts to improve international relations and stop the spread of nuclear weapons.
1975 *Andrei D. Sakharov (Soviet) for his work in promoting peace and opposing violence and brutality.
1976 Mairead Corrigan and Betty Williams (Irish) for organizing a movement to end Protestant-Catholic fighting in Northern Ireland. (Award delayed until 1977.)
1977 Amnesty International for helping political prisoners.
1978 *Menachem Begin (Israeli) and *Anwar el-Sadat (Egyptian) for their efforts to bring about a settlement of the Arab-Israeli conflict.
1979 *Mother Teresa (Indian) for aiding India's poor.
1980 Adolfo Pérez Esquivel (Argentine) for his role in Service

*Has a biography in *World Book.*

Karsh, Ottawa, from Pix

Lester B. Pearson was the first Canadian to win the peace prize. He won the 1957 award for his work in the United Nations.

Wide World

Martin Luther King, Jr., won the 1964 peace prize for leading nonviolent civil rights demonstrations in the United States.

Nobel Peace Prizes (continued)

for Peace and Justice in Latin America, a group promoting the cause of human rights.

1981 Office of the United Nations High Commissioner for Refugees for protection of millions of Vietnamese and other refugees.

1982 *Alva R. Myrdal (Swedish) and Alfonso García Robles (Mexican) for their contributions to United Nations disarmament negotiations.

1983 *Lech Wałęsa (Polish) for his efforts to prevent violence while trying to gain workers' rights.

1984 *Desmond Tutu (South African) for leading a nonviolent campaign against racial segregation in his country.

1985 International Physicians for the Prevention of Nuclear War for educating the public on the effects of nuclear war.

1986 *Elie Wiesel (American) for his vigorous efforts to help victims of oppression and racial discrimination.

1987 *Oscar Arias Sánchez (Costa Rican) for authoring a plan to end civil wars in Central America.

1988 The United Nations peacekeeping forces for helping control military conflict in the Middle East and other areas.

1989 *The Dalai Lama (Tibetan) for his nonviolent struggle to end China's rule of Tibet.

1990 *Mikhail S. Gorbachev (Soviet) for his efforts to promote world peace, including his role in reducing tensions between Communist and non-Communist countries.

1991 *Aung San Suu Kyi (Burmese) for her nonviolent struggle for democracy and human rights in Myanmar.

1992 *Rigoberta Menchú (Guatemalan) for her work to gain respect for the rights of Guatemala's Indian peoples.

1993 *Nelson Mandela and *Frederik W. de Klerk (South African) for working to end apartheid in South Africa and to enable its nonwhites to fully participate in government.

1994 *Yasir Arafat (Palestinian), *Shimon Peres (Israeli), and *Yitzhak Rabin (Israeli) for their efforts to create peace in the Middle East.

1995 The organization known as the Pugwash Conferences on Science and World Affairs and its president, Joseph Rotblat (British), for efforts to eliminate nuclear weapons.

1996 Carlos Ximenes Belo (Timorese) and José Ramos-Horta (Timorese) for work on behalf of the people of East Timor.

1997 International Campaign to Ban Landmines and its coordinator, Jody Williams (American), for their work to end the use of land mines worldwide.

1998 John Hume (British) and David Trimble (British) for working to end Protestant-Catholic fighting in Northern Ireland.

1999 †Doctors Without Borders (French) for its pioneering work in providing medical care and humanitarian aid to victims of disasters on several continents.

2000 Kim Dae Jung (South Korean) for his efforts to end hostility between North Korea and South Korea.

2001 *Kofi Annan (Ghanaian) and the United Nations for their efforts to build peace and security throughout the world.

Bank of Sweden Prizes in Economic Sciences in Memory of Alfred Nobel

1969 *Ragnar Frisch (Norwegian) and *Jan Tinbergen (Dutch) for their work in *econometrics,* a method of analyzing economic activity.

1970 *Paul A. Samuelson (American) for raising the level of scientific analysis in economic theory.

1971 *Simon Kuznets (American) for his interpretation of economic growth.

1972 *Kenneth J. Arrow (American) and Sir John Hicks (British) for their pioneering contribution to general equilibrium theory and to welfare theory.

1973 Wassily Leontief (American) for his development of the input-output method of economic analysis.

1974 Friedrich von Hayek (Austrian) and *Gunnar Myrdal (Swedish) for their work in the theory of money and economic change and in the relationship between economic and social factors.

1975 Leonid V. Kantorovich (Soviet) and Tjalling C. Koopmans (American) for their work on how economic resources should be distributed and used.

1976 *Milton Friedman (American) for his work in the fields of economic consumption, monetary history and theory, and price stabilization policy.

1977 James Meade (British) and Bertil Ohlin (Swedish) for their studies of international trade and finance.

1978 *Herbert A. Simon (American) for his research on the decision-making process in business.

1979 *Sir Arthur Lewis (St. Lucian-born) and Theodore W. Schultz (American) for their research into the economic problems of developing countries.

1980 *Lawrence R. Klein (American) for using econometric models to analyze economic policies and the rise and fall in business activity.

1981 James Tobin (American) for his analyses of financial markets and their effect on how businesses and families spend and save money.

1982 George Stigler (American) for his research on industrial organization, markets, and regulation.

1983 Gerard Debreu (American) for developing a mathematical model that proved the theory of supply and demand.

1984 Sir Richard Stone (British) for developing methods of measuring the performance of national economies.

1985 Franco Modigliani (American) for his theories on personal savings and financial markets.

1986 James M. Buchanan (American) for developing methods of analyzing the decision-making process in government.

1987 *Robert Solow (American) for his development of a mathematical model that identified technology as the dominant factor in long-term economic growth.

1988 Maurice Allais (French) for his theories on economic markets and the efficient use of resources.

1989 Trygve Haavelmo (Norwegian) for his development of statistical techniques that led to the creation of mathematical models used in making economic predictions.

1990 Harry M. Markowitz, Merton H. Miller, and William F. Sharpe (American) for their theories in corporate finance.

1991 Ronald H. Coase (British-born) for his theories on the economic importance of property rights and of the costs of carrying out business transactions.

1992 Gary S. Becker (American) for extending economic theory to aspects of behavior that previously had been dealt with only by such fields as sociology and criminology.

1993 Robert W. Fogel and Douglass C. North (American) for their work in economic history.

1994 John F. Nash (American), John C. Harsanyi (American), and Reinhard Selten (German) for their work in game theory.

1995 Robert E. Lucas, Jr. (American), for his analysis of the impact of government economic policies on the economic decisions of individuals.

1996 William S. Vickrey (American) and James A. Mirrlees (British) for their contributions to the economic theory of incentives.

1997 Robert C. Merton and Myron S. Scholes (American) for devising a method of determining appropriate prices for financial options.

1998 Amartya Sen (Indian) for his studies of such problems as famine and poverty from an ethical point of view.

1999 Robert A. Mundell (Canadian-born) for his theories on how international factors affect governments' efforts to stabilize their economies.

2000 James Heckman and Daniel McFadden (American) for their work in the statistical analysis of the economic behavior of individuals and households.

2001 George A. Akerlof, A. Michael Spence, and Joseph E. Stiglitz (American) for their research on how buyers and sellers with different amounts of information affect market systems.

*Has a biography in *World Book.* †Has a separate article in *World Book.*

Nobelium is an artificially produced radioactive element. It has an *atomic number* (number of protons) of 102. Its chemical symbol is No. Scientists have discovered 11 *isotopes* of nobelium, forms of the element with the same number of protons but different numbers of neutrons. These isotopes have *atomic mass numbers* (total numbers of protons and neutrons) from 250 to 260. The most stable isotope has a mass number of 259 and a *half-life* of 58 minutes—that is, due to radioactive decay, only half the atoms in a sample of isotope 259 would still be atoms of that isotope after 58 minutes.

In 1957, scientists at the Nobel Institute for Physics in Stockholm, Sweden, claimed that they had produced an element whose atomic number was 102. They proposed to name the element *nobelium* in honor of Swedish inventor Alfred Nobel. However, no other laboratory could confirm their claim.

In 1958, scientists at Lawrence Radiation Laboratory (now Lawrence Berkeley National Laboratory) in Berkeley, California, published the first in a series of claims that they had created element 102. In addition, the Berkeley scientists proposed the name *nobelium*. The International Union of Pure and Applied Chemistry (IUPAC) accepted this name. The IUPAC is the recognized authority in crediting the discovery of elements and naming them.

In the 1950's and 1960's, the Joint Institute for Nuclear Research (JINR) in Dubna, Russia, near Moscow, claimed that its scientists had discovered element 102. In 1986, the IUPAC and the International Union of Pure and Applied Physics formed a working group to review the histories of the elements with atomic numbers from 101 to 109. In 1993, the IUPAC accepted the working group's conclusion that the discovery of element 102 was first proved in 1966 at the JINR. The JINR scientists had bombarded americium, whose atomic number is 95, with nitrogen, whose atomic number is 7. Richard L. Hahn

Nobility is a class of people who are considered to stand at the top of their society. They have special political and social status. Nobility is inherited, and it carries titles such as *duke* or *earl*. Some nobles are the descendants of lords of the Middle Ages and have inherited their property as well as their titles. Others trace their ancestry to a person who was awarded a title for service to a modern monarch.

In the United Kingdom

The British nobility is called the *peerage*, and noblemen are known as *peers*. There are five grades of peers. From the highest to the lowest, they are: (1) duke; (2) marquess, or marquis; (3) earl; (4) viscount; and (5) baron. The wives of noblemen, and women who hold titles in their own right, are called *peeresses*. The five grades of peeresses are: (1) duchess, (2) marchioness, (3) countess, (4) viscountess, and (5) baroness.

The title of earl is the oldest grade of peer. It dates back to the Danish nobles who ruled much of England from the 800's to the 1000's. The rank of baron was introduced by the Normans when they conquered England in 1066. King Edward III of England created the rank of duke in 1337, when he named his oldest son as Duke of Cornwall. The title of marquess was added to the peerage in 1385, and the first viscount was introduced in 1440.

The creation of peerages. The British monarch now grants peerages on the recommendation of the prime minister. The monarch issues documents called *letters patent*, which create the peerage and specify how it will be inherited. In most cases, a peer's title passes to his oldest son. If he has no son, it usually goes to his closest male relative. The other children are commoners. The title becomes extinct if there is no male heir.

Some medieval peerages were created by royal orders called *writs of summons*. These types of peerages may pass to a daughter if the holder leaves no male descendant. If the daughter then has a son, he usually inherits the title.

Today, the British monarch rarely grants hereditary peerages. Each year, however, the monarch may grant titles called *life peerages* to distinguished persons. A life peerage involves the same privileges as a hereditary peerage, but it does not descend to the holder's children. Life peerages may be awarded to both men and women, and the title given is baron or baroness. Today, there are about 1,300 peers, including about 750 hereditary peers and about 600 life peers.

Privileges of the peerage. Until 1999, all peers who were at least 21 years old—except peers of Ireland and individuals who had been declared bankrupt or insane—were summoned to the House of Lords. The House of Lords is the upper house of the British Parliament. In 1999, reforms began that limited the number of hereditary peers sitting in the House of Lords to about 90. Life peers continued to serve as members of the Lords.

Peers are summoned because of the feudal agreement that lords and vassals should consult on important business. Women who are peeresses in their own right may also serve in the House of Lords. Peers who are serving in the House of Lords may not also serve in the lower house of Parliament—the House of Commons—and they cannot vote in parliamentary elections. Until 1948, peers accused of a felony or of treason had the right to be tried in the House of Lords by their fellow peers.

Dukes, marquesses, and earls have lesser titles besides the one by which they are known. Traditionally, the oldest son of one of these peers uses the highest of his father's lesser titles as a *courtesy title*. For example, the oldest son of the Duke of St. Albans uses the courtesy title Earl of Burford, but he is not a peer. A younger son of a duke adds *Lord* to his name, as in Lord Peter Grey. His sister would be Lady Helen Grey.

In other countries

In most other countries, titles of nobility have been officially abolished. A person who inherits a title may use it as part of his or her name. But the individual has none of the privileges of the former nobility. Titles of nobility were abolished in France in 1871, in Russia in 1917, in Germany in 1918, and in Japan—except those of the imperial family—in 1946. The titles were often abolished as part of a revolution or a major social and political effort to modernize the country.

The Constitution of the United States forbids the government to give anyone a title of nobility. The Constitution also prohibits federal officials from accepting any title from a foreign country without the special consent of Congress. Joel T. Rosenthal

Noble gas refers to any of a group of six chemical elements. These elements are argon (Ar), helium (He), krypton (Kr), neon (Ne), radon (Rn), and xenon (Xe). They occur naturally and can be found in the atmosphere. The British scientists Lord Rayleigh and William Ramsay discovered the noble gases during the late 1890's.

Unlike most gaseous elements, the noble gases are *monatomic*—that is, they occur as single atoms instead of as molecules of two or more atoms. The atoms have stable *configurations* (arrangements) of electrons. Therefore, the atoms do not, under normal conditions, gain or lose electrons or share electrons with other elements. The six gases are called "noble gases" or *inert gases* because they do not readily react with other elements. But krypton, radon, and xenon do combine with fluorine and oxygen to form compounds.

The noble gases have various uses. Except for radon, which is highly radioactive, all of them are used as light sources in incandescent and gaseous-discharge lamps (see **Electric light**). Some also are used in devices called *gas lasers* (see **Laser** [Kinds of lasers]).

Argon and helium are used in a welding process called *arc welding*. They provide a chemically inactive atmosphere in which certain metals, such as aluminum, can be heated to their melting points without reacting chemically. Helium also is used in balloons that carry scientific instruments high into the atmosphere, and in low-temperature research. Each noble gas has a separate article in *World Book*. Frank C. Andrews

The Seed, left, Strange Bird, center, and *Metamorphosis, right,* in white marble and slate (Michio Noguchi, Isamu Noguchi Garden Museum)

Isamu Noguchi's sculptures typically portray abstract forms in arrangements of smooth, highly polished stone.

Noël. See Christmas.

Noguchi, Isamu (1904-1988), was an American sculptor whose work represents a wide variety of styles. Noguchi said that he was "suspicious of the whole business of style." He called style "a form of inhibition."

Noguchi worked in nearly every sculptural material. Almost all his work has no recognizable subject matter. Noguchi sought to preserve the nature of the sculptural material. He was intrigued by problems of weight, mass, and tension, which he used as themes.

Noguchi was born on Nov. 17, 1904, in Los Angeles. His mother was an American, and his father was a well-known Japanese poet and scholar. Noguchi lived in Japan from the age of 2 until he was 13. He gave up medical studies at Columbia University to return to sculpture, his earlier ambition. In the late 1920's, he studied in Paris with the Romanian-born sculptor Constantin Brancusi, who strongly influenced his work. Noguchi designed furniture and settings for ballets. He also collaborated with architects in planning gardens, playgrounds, and bridges. He died on Dec. 30, 1988.

George Gurney

Noise is random or unwanted sound. Unwanted signals, such as static that interferes with radio transmission, are also referred to as noise. The sound we hear is caused by vibrations of air molecules. A tuning fork produces an almost *pure tone,* with only one *frequency,* or rate of vibration (see **Tone**). Musical instruments produce *harmonic sound.* Such sound contains many frequencies, called *overtones,* that are harmonically related (see **Harmonics**). *Random sound* has many overtones that are not harmonically related.

Unwanted sound can be caused by any kind of sound—tones, harmonic sound, or random sound. Sound is unwanted if it is annoying or distracting, or if it damages the hearing mechanism. Thomas A. Griffy

See also **Acoustics; Decibel; Muffler; Sound.**

Nok, *nahk,* was a West African civilization that flourished from about 500 B.C. until around A.D. 200. Archaeologists became aware of Nok in the 1940's, when small clay statues were discovered along the Jos Plateau in central Nigeria. These statues are the oldest sculptures ever found in Africa south of the Sahara. Bernard Fagg, a British archaeologist, studied these sculptures and other objects to learn about Nok's people and culture. Fagg determined that Nok was spread along an area between the Niger and Benue rivers, southwest of the Jos Plateau. He named the culture Nok after the modern-day Nigerian village of Nok, where the statues were discovered.

The Nok sculptures are human and animal figures made of *terra cotta* (baked clay). Most stand no more than a foot (30 centimeters) high, but some are nearly life-sized. Distinctive features of Nok sculpture include a semicircular or triangular shape of the eyes. Most figures are hollow, with holes in the pupils, ears, noses, and mouths. Scholars are unsure what function the sculptures served. The figures may have been placed above the front doors of houses or displayed on altars.

Nok's people were among the earliest ironworkers in Africa. They used low, circular iron-smelting furnaces. They also worked with some stone tools, particularly polished stone axes.

Little is known about the details of Nok society. Ar-

chaeologists' efforts to learn more about Nok have been hindered by looting of the Jos region. Thieves have taken many of the terra-cotta sculptures and sold them on the international art market. Kevin C. MacDonald

Nomad is a person who moves from one place to another to make a living. The word *nomad* comes from a Greek word that means *one who wanders for pasture.* Most nomadic peoples move through a certain area according to a cycle based on their activities and the seasons. Nomads traditionally travel by animal or canoe or on foot. Today, however, some nomads travel by motor vehicle. Most live in tents or other portable shelters.

Nomads keep moving for different reasons. For example, *hunting and gathering nomads* move in search of game, edible vegetation, and water. The African Pygmies, Australian Aborigines, and Negritos of Southeast Asia camp in different places to hunt animals and gather wild plants. Some American Indians followed this way of life. *Pastoral nomads* travel to find water and pastures for their herds. Bedouin herders move camels, sheep, and goats through the deserts of Arabia and northern Africa. The Fulani and their cattle travel through the grasslands of Niger in western Africa. *Nomadic craftworkers* and *merchants,* such as the Lohar blacksmiths of India and the Gypsy traders, travel to serve their customers. Nomadic peoples, especially herders, may also move to attack settled communities or avoid enemies.

Most nomads travel in groups of families called bands or tribes. These groups are based on kinship and marriage ties or on formal agreements of cooperation. A council of adult males makes most of the decisions, though some tribes have chiefs. Philip Carl Salzman

Nome (pop. 3,505) is an important gold-mining center and port in Alaska. It lies along Norton Sound of the Bering Sea (see **Alaska** [political map]).

Gold mining is Nome's chief industry. The tourist and building industries and government agencies are also main sources of jobs. The port of Nome is open from June to October. Ice blocks it in winter. Eight airlines serve the region. The city has three radio stations and cable television. The *Nome Nugget,* first published in 1900, is Alaska's oldest newspaper.

Inuit (also called Eskimos) make up about half of Nome's people. Many Inuit hunt and fish to support themselves, and many also carve ivory ornaments and statues for sale. Nome is the finish for the Annual World-Classic Iditarod Trail Sled Dog Race, which begins in Anchorage, Alaska.

Nome sprang up suddenly in 1899, when gold was discovered nearby. Within a year, thousands of miners, merchants, and adventurers had set up a city of tents. The city got its name when a mapmaker misread the term *? name* on a chart and recorded it as *C. Nome,* or *Cape Nome.* Nome was incorporated in 1901. By that year, prospectors could no longer find significant gold deposits, and many began to leave Nome. The city has a council-manager government. Nancy L. McGuire

Nominative case. See Case.

Nonaggression pact is a treaty by which two or more nations agree to settle mutual disputes peacefully and not to attack each other. Between World War I (1914-1918) and World War II (1939-1945), many nations signed nonaggression pacts because there was no international force strong enough to prevent aggression.

Nonaggression pacts sometimes were not effective because they lacked enforcement procedures, and also because participating nations violated their agreements. For example, during the 1920's and 1930's, the Soviet Union signed pacts with many of its neighbors. But the Soviet Union violated its agreements with Estonia, Latvia, and Lithuania when it occupied them in 1939 and 1940. Germany signed a nonaggression pact with the Soviet Union in 1939 but attacked the Soviets in 1941.

Since the end of World War II, there have been fewer attempts to establish nonaggression pacts. Many nations feel that the United Nations Charter contains adequate provisions for the peaceful settlement of disputes.

A major problem with nonaggression pacts is to decide an acceptable definition of *aggression.* The UN has debated this question but has not reached any agreement. Some nations believe aggression includes only direct military attacks. Others feel that when one country aids revolution in another country through propaganda, subversion, or by taking over government posts, it constitutes indirect aggression. Robert J. Pranger

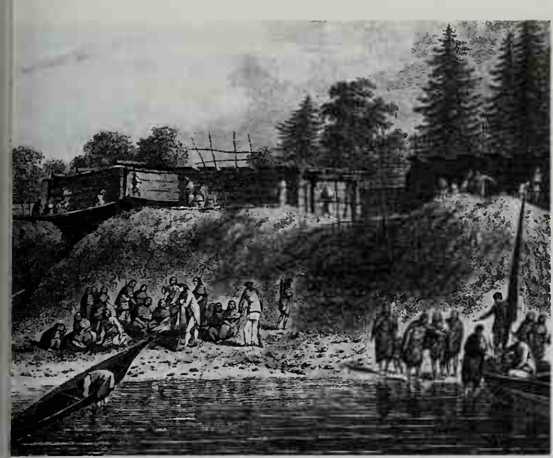
Nonpartisan League, *nahn PAHR tuh zuhn,* a political organization of farmers, was founded in North Dakota in 1915. It is sometimes called the NPL. From 1916 to 1921, the NPL dominated the government of North Dakota, where it enacted many socialistic policies. In 1919, the state legislature set up a state-owned bank, grain elevator, insurance fund, and other institutions important to farmers and workers. NPL candidates ran officially as Republicans. In Minnesota, the NPL helped create the Farmer-Labor Party (see **Farmer-Labor Party**).



During and after World War I (1914-1918), the NPL was criticized as unpatriotic because of its neutral position on the war and its socialist goals. Its power declined after 1921 but revived during the Great Depression of the 1930's. In 1956, the NPL aligned itself with the Democratic Party in North Dakota. Robert W. Cherny

Detail of *Habitations at Nootka Sound* (1784), an engraving after a drawing by John Weber; Royal British Columbia Museum, Victoria

The Nootka Indians fished and hunted whales off the Northwest Coast of North America. They built houses of cedar planks.

Nootka Indians, *NOOT kuh,* live along the west coast of Vancouver Island in British Columbia and at the tip of the Olympic Peninsula in Washington. Those on Vancouver Island call themselves the *Nuu-chah-nulth* or *West Coast natives.* Those living in Washington call themselves the *Makah.* There are more than 7,000 Nootka. They make their living mainly by fishing and lumbering in their traditional lands or by working in factories and offices in nearby cities. Many still speak dialects of the Nootkan language.

The Nootka were once noted for their skill in hunting whales from graceful dugout canoes. They lived in wooden plank houses on sheltered beaches and coves. Nootka artists carved and painted masks, large puppets, totem poles, and other objects used in religious ceremonies and in feasts called *potlatches.* The Nootka were first described in detail by the British navigator Captain James Cook in 1778. In the late 1700's and the 1800's, they were devastated by diseases introduced by Europeans, Americans, and Canadians. These peoples colonized most of the Nootka land. Robert S. Grumet

NORAD is a military alliance responsible for defending the United States and Canada against air attack. NORAD stands for *No*rth American *A*erospace *D*efense Command. It oversees a large network of radars and other sensing devices that can detect and track approaching enemy bombers and missiles, artificial satellites, and other objects from earth in space.

NORAD was established in 1957. It has headquarters at Peterson Air Force Base near Colorado Springs, Colorado, and an underground command center at nearby Cheyenne Mountain. The commander in chief of NORAD is traditionally a general in the U.S. Air Force, and the second in command is a Canadian general. In the event of an attack, NORAD would relay information to the U.S. president and the Canadian prime minister, who would decide on a response. NORAD can oppose a bomber or cruise missile attack with antiaircraft missiles and fighter aircraft. The U.S. Air Force, Army, and Navy support NORAD through a unified command known as U.S. Space Command. Wayne Thompson

Nordenskjöld, *NOOR duhn SHOOLD,* **Nils Adolf Erik,** *nihls AH dawlf AY rihk* (1832-1901), Baron Nordenskjöld, was a Swedish polar explorer, mineralogist, and map authority. In 1878 and 1879, he became the first person to sail through the Northeast Passage between the Atlantic and Pacific oceans. He sailed along the northern coast of Europe and Asia. He tells of this journey in his book, *Voyage of the Vega* (1881).

Nordenskjöld was born on Nov. 18, 1832, in Helsinki, Finland. He moved to Sweden in 1857 and became a Swedish citizen. He led two expeditions in an attempt to reach the North Pole. On the first one in 1868, he took his ship, the *Sofia,* to within about 575 miles (925 kilometers) of the Pole. Nordenskjöld studied the geology of Greenland in 1870. He returned there in 1883 and penetrated the ice barrier off the east coast. He determined that ice covered the island's interior. William Barr

Nordhoff and Hall were a team of American authors. Charles Bernard Nordhoff (1887-1947) and James Norman Hall (1887-1951) became famous for their three novels about an actual mutiny in the British Navy in 1789. These novels are *Mutiny on the Bounty* (1932), *Men Against the Sea* (1934), and *Pitcairn's Island* (1934). The first novel describes how the crew of the *Bounty* mutinied against their cruel captain, William Bligh. The second novel tells about the hardships of Bligh and his followers after they were set adrift in a small boat. The final novel follows the lives of the crew and their descendants after they settled on Pitcairn Island and Norfolk Island in the South Pacific Ocean.

Nordhoff was born on Feb. 1, 1887, in London, and Hall was born on April 22, 1887, in Colfax, Iowa. They met while serving as pilots in the *Lafayette Escadrille,* a French and American air squadron, during World War I (1914-1918). In 1920, they sailed for Tahiti, where they lived for many years. The men wrote several novels together as well as works individually. Samuel Chase Coale

Norfolk, *NAWR fuhk,* Virginia (pop. 234,403), is a leading United States port. It lies in southeastern Virginia (see **Virginia** [political map]). Norfolk is the state's second largest city. Only Virginia Beach has more people. Norfolk, Virginia Beach, and Newport News form a metropolitan area with 1,569,541 people.

Hampton Roads, one of the world's finest natural deepwater harbors, forms Norfolk's northwestern boundary. The Norfolk Naval Station employs more people and harbors more ships than any other naval base in the United States. It also serves as headquarters of the Allied Command Atlantic of the North Atlantic Treaty Organization (NATO).

In 1680, the Virginia General Assembly founded a port in Norfolk County to serve ships sailing to and from England and the West Indies. The port was later named Norfolk for the county. It became an independent borough in 1736 and an independent city in 1845.

Description. Norfolk covers 66 square miles (171 square kilometers). The Elizabeth River borders the city on the west. Chesapeake Bay is on the north.

Features of downtown Norfolk include a cultural and convention center called Scope. This complex includes

Chrysler Hall, where the Virginia Symphony performs. Norfolk's Chrysler Museum houses a large art collection. Nauticus, the National Maritime Center, celebrates the region's seafaring heritage. Next to Nauticus on the downtown waterfront, the World War II battleship U.S.S. *Wisconsin* is open for tours.

The city's colleges and universities include Norfolk State University, Old Dominion University, Tidewater Community College, and Virginia Wesleyan College. Norfolk is also home to Eastern Virginia Medical School.

Every spring, a number of visitors come to Norfolk for the International Azalea Festival or for a festival called Harborfest. Many tourists also visit St. Paul's Church, which dates from 1739. This church was one of only a few buildings that survived a British bombardment during the Revolutionary War in America (1775-1783).

Economy of Norfolk depends heavily on its port. The Norfolk Naval Station is the city's largest employer. The Norfolk International Terminals (NIT) is a huge center on the waterfront for loading and unloading cargo from container ships from all over the world. The cargo is loaded onto trucks and trains for distribution across North America. NIT and terminals in the neighboring cities of Portsmouth and Newport News make up the Virginia International Terminals, which handle millions of tons of cargo a year.

Government and history. Norfolk has a council-manager form of government. The voters elect seven council members to four-year terms. The council members choose one of their group as mayor and hire a city manager to carry out their policies.

Powhatan Indians lived in what is now the Norfolk area when European explorers first arrived there in the early 1600's. Early Norfolk served as a tobacco and naval supply port. In 1776, during the Revolutionary War, a British fleet bombarded and destroyed much of the town. Norfolk was incorporated as a city in 1845.

The city grew slowly until the Navy began to build the Norfolk naval base in 1917, shortly after the nation entered World War I. During World War II (1939-1945), thousands of civilians moved to the city to work in the navy yards and on the base. The population of Norfolk rose from 144,332 in 1940 to 213,513 in 1950.

The city launched an urban renewal program in 1951 that included slum clearance and the construction of public housing. During the 1970's, the city constructed several high-rise buildings and a waterfront hotel. In 1983, Waterside, a festival marketplace, was completed on the downtown waterfront. Downtown revitalization continued through the late 1900's and into the 2000's. MacArthur Center Mall opened in 1999 Elizabeth Thiel

For the monthly weather in Norfolk, see **Virginia** (Climate). See also **Norfolk Naval Base.**

Norfolk Island, *NAWR fuhk,* lies in the South Pacific Ocean, about 1,000 miles (1,600 kilometers) northeast of Sydney, Australia. For location, see **Pacific Islands** (map). Many of the island's inhabitants are descendants of crew members of the British naval ship *Bounty.* In 1789, those sailors of the *Bounty* mutinied against the way they were treated by their captain, William Bligh. They settled on Pitcairn Island in 1790. In 1856, 194 of their descendants moved to Norfolk Island.

Norfolk Island covers 14 square miles (36 square kilometers). It has a population of about 2,000. Tourism is the main source of income. Norfolk Island has fertile soil. The people grow bananas, citrus fruits, and vegetables.

In 1774, the British explorer James Cook became the first European to reach Norfolk Island. From 1788 to 1814, the island was used as a penal settlement by the Australian state of New South Wales. It again served as a penal settlement from 1825 until 1856, when the settlement was abolished. In 1914, the island was separated from New South Wales and became a territory of Australia. In 1979, the Norfolk Island Act set up a Legislative Assembly and Executive Council to handle local government matters on the island. The act preserved Australia's overall responsibility for the island. Garry R. LeDuff

Norfolk Naval Base, *NAWR fuhk,* Virginia, employs more people and harbors more ships than any other naval base in the United States. It includes the headquarters of the Atlantic Fleet, the Fifth Naval District, and the North Atlantic Treaty Organization (NATO) Allied Command Atlantic. Commissioned in 1917, the base houses the Armed Forces Staff College and the oldest supply center in the Navy. The base covers about 5,000 acres (2,000 hectares). Nearby are the Naval Amphibious Base at Little Creek, a weapons station at Yorktown, and a shipyard at Portsmouth. W. W. Reid

Norfolk terrier, *NAWR fuhk,* is a breed of dog that originated in the United Kingdom. Norfolk terriers and Norwich terriers were exhibited at dog shows as one breed until 1964. That year, the Kennel Club in England registered them as separate breeds. The main difference between the two breeds is the way they carry their ears. Norfolks have ears that drop forward, and Norwich terriers have ears that stand erect. The American Kennel Club recognized the dogs as separate breeds in 1979.

The Norfolk terrier is hardy and active and instinctively hunts small animals. It was originally bred as a companion dog and makes a fine pet.

The Norfolk terrier may be black and tan, or any shade of red. It has a straight, wiry outer coat and a harsh undercoat. The dog has short, sturdy legs. The tail is sometimes *docked* (cut) to 3 or 4 inches (8 to 10 centimeters) in length. A full-grown Norfolk weighs from 10

WORLD BOOK photo by Tom Weigand

The Norfolk terrier is an affectionate pet.

to 12 pounds (4.5 to 5.4 kilograms) and stands about 10 inches (25 centimeters) tall at the shoulder.

Critically reviewed by the Norwich and Norfolk Terrier Club

Norgay, Tenzing. See Tenzing Norgay.

Noriega, *nawr YAY gah,* **Manuel Antonio,** *mah NWEHL* (1934-), was a military leader who controlled Panama from 1983 to 1989. In December 1989, United States President George H. W. Bush ordered troops into Panama. Bush said the troops were a response to the killing of a U.S. marine lieutenant by Panamanian soldiers and charges of drug trafficking against Noriega. In January 1990, Noriega surrendered to U.S. officials and was taken to the United States to stand trial. In 1992, he was convicted on charges of drug trafficking, money laundering, and racketeering and was sent to prison. In 1993 and 1994, Panamanian courts convicted Noriega of involvement in the murders of two of his political opponents, and in 1999, a French court convicted him of money laundering. Noriega did not leave prison for any of those trials.

Reuters/Bettmann

Manuel Noriega

Noriega was born in Panama City. He graduated from a military academy in Peru in 1962. That year, Noriega enlisted in Panama's military, which soon made him a lieutenant. Following a military take-over of the government in 1968, he quickly rose through the ranks. Noriega became commander of Panama's military intelligence agency in 1970 and expanded his power because of the secret knowledge he possessed. Noriega took charge of the military in 1983 and became increasingly involved in the drug trade in Latin America. Beginning in 1987, the United States tried to force him to resign. In 1988, two U.S. federal grand juries in Florida indicted Noriega on charges of drug trafficking and racketeering.

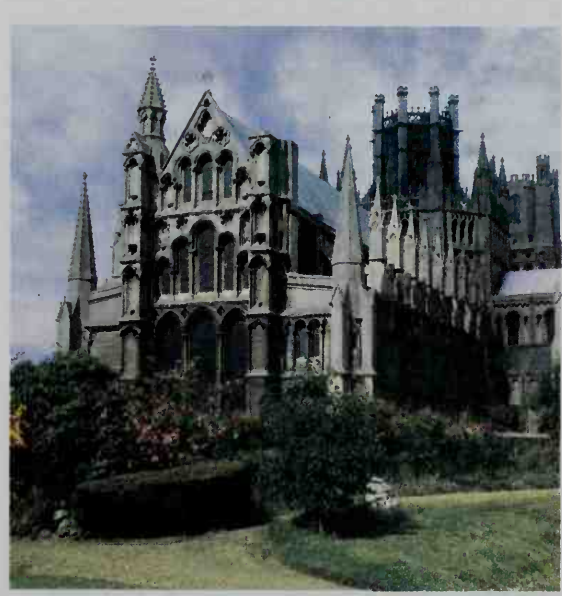
Steve C. Ropp

Norman architecture is a regional adaptation of Romanesque architecture. It originated in Normandy in northwest France. The style reached its highest development in England during the late 1000's, after the Norman Conquest of 1066, and in the 1100's.

Norman architecture is noted for its massive character, development of the six-part vault ceiling, and the use of Celtic and Carolingian patterns of carved ornamentation. Examples of the style include the churches of St. Étienne and La Trinité in Caen, France, and Ely and Durham cathedrals in England. J. William Rudd

See also **Architecture** (picture: Romanesque architecture).

Norman Conquest is the name given to the conquest of England in 1066 by William, Duke of Normandy. The duke, who was also known as William the Conqueror, led a Norman army across the English Channel into England (see **Normans**).



William was a proud and ruthless ruler and a vassal of the king of France. He hoped to follow his distant cousin, King Edward the Confessor, as king of England. William claimed that Edward had named him as his successor. The chief English contender for the throne was Harold, Earl of Wessex. But William also claimed that Harold, who had visited Normandy in 1064, had sworn a solemn oath to support William's claim to the throne. In 1066, King Edward died. The Anglo-Saxon Witan (Great Council) chose Harold as king (see **Harold II**).

William at once declared his right to the throne. He claimed to have the support of the pope and gathered an army from northern France. William landed in England without opposition at Pevensey, between Eastbourne and Hastings.

The Normans were aided in their successful landing by a chance happening. While Harold was waiting for the Normans to arrive, he got news that a Norwegian force had landed in the north of England. He hastened north and defeated the Norwegians. Meanwhile, William's forces landed on the unprotected coast. Harold then marched back across England. But as he neared Hastings, he was attacked by William on Oct. 14, 1066. This was the historic Battle of Hastings, which established the Norman rule of England. Harold was defeated and slain. William entered London and was crowned king of England on Christmas Day, 1066. At first, he tried to win over the English nobles. But they opposed him stubbornly, and he spent several years subduing them.

William established Norman rule in England on a strong foundation. He hesitated at no act that he thought would increase the power of the crown. William took almost all the land of the English nobility, keeping some of it for himself and dividing most of the rest among his Norman followers. William forced all landholders to swear loyalty to himself. In this way, he put all the lords of England under his direct control. In order to know the conditions in England, William directed the preparation of the famous Domesday Book, a survey of all the regions in his kingdom (see **Domesday Book**).

The descendants of the Normans became the ruling

Ace Williams, Shostal

Norman architecture flourished in England in the 1000's and 1100's. Ely Cathedral, *shown here,* is a masterpiece of the style.

Detail of the Bayeux Tapestry (late 1000's), embroidery on linen by unknown artists; William the Conqueror Center, Bayeux, France (SCALA/Art Resource)

The Norman Conquest of England began in 1066 when William the Conqueror sailed his army across the Channel.

class in England. For a time, they kept themselves aloof from the Anglo-Saxons and treated them as a conquered people. But as the years went by the Normans and the Anglo-Saxons intermarried. The two peoples, which even in the beginning were similar, blended into one. Today, many English families claim—though few can prove—descent from the Norman conquerors.

The Normans contributed much to the English language and to English literature and architecture. At first, the Normans spoke French. Later, the Norman French blended with the Germanic tongue of the Anglo-Saxons and became English. John Gillingham

Normandy is a region in northwestern France. It was named after the Norse people who conquered the area in the 800's. It lies along the English Channel coast between the regions of Picardy and Brittany (see **France** [political map]). Famous towns include Rouen, the capital of the old province; Le Havre, a leading port; Honfleur; Caen; Bayeux; and Cherbourg. The inhabitants are well known as sailors and farmers. The farmers specialize in dairying and raising fruits, especially apples for cider and brandy. Iron ore is mined near Caen. Tourism is an important industry along the coast.

In A.D. 911, the Carolingian king, Charles the Simple, granted much of what is now Normandy to the Norman chieftain Rollo, or Hrolf. One of Rollo's most famous descendants was William the Conqueror, who won the English crown after the Battle of Hastings in 1066. Events of the battle are pictured on the famous Bayeux Tapestry, a medieval wallhanging housed in the William the Conqueror Center in Bayeux, France. Normandy was united with England during the reign of the English king Henry I (1100-1135). England and France struggled for control of Normandy during the Hundred Years' War. The English recovered the region twice, but finally lost it in 1449 to Charles VII, king of France. Joan of Arc became famous as the leader of French troops in the fight for Normandy.

Normandy attracted worldwide attention on June 6, 1944, when Allied troops landed on its beaches. From Normandy, the Allies drove the Germans out of France. Many of the towns in Normandy were damaged in the fighting. Hugh D. Clout

Normandy, Duke of. See **William I, the Conqueror.**

Normans were a group of Vikings, or *Norsemen* (Scandinavians), who first settled in northern France, then advanced into England, southern Italy, and Sicily. In the 800's, Norman warriors began their conquests by raiding French coasts and river valleys. By the early 900's, they had settled in the French territory near the mouth of the Seine River now known as Normandy. In 911, the Carolingian king, Charles the Simple, granted much of the region to the Norman chief, Rollo, or Hrolf, and Rollo became the king's vassal. The Normans became Christians and adopted French customs. Many became famous administrators, clergymen, and crusaders.

Norman power grew after 950. The Normans invaded the Rhineland, an area in present-day Germany. In 1066, under the leadership of William, Duke of Normandy, they conquered England. After the conquest, Norman influence spread steadily throughout what are now the United Kingdom and Ireland. (see **William I, the Conqueror**). In the same period, Normans won great victories in other lands. Robert Guiscard (1015?-1085), son of Tancred of Hauteville, conquered southern Italy. Roger, another of Tancred's sons, took the island of Sicily from the Muslims. These two territories were later united in the famous Kingdom of the Two Sicilies by Roger's son, Roger II. Major advances in architecture and sculpture occurred in the period of Norman domination in western Europe. An architectural style called *Romanesque* owed much to the Normans. Malcolm Todd

See also **Norman Conquest; Normandy; Vikings.**

Norns were the three Fates of Scandinavian mythology. They were three sisters: Urd (Past), Verdandi (Present), and Skuld (Future). Urd was old and looked toward the past. Verdandi faced straight ahead into the present. Skuld represented the future, and looked in a direction opposite from that of Urd. The fate of people and gods was decided by the Norns. The early Scandinavians believed that there were many lesser Norns, and one for each person. C. Scott Littleton

Norodom Sihanouk (1922-), *NAWR uh dum SEE uh nuk,* is the king of Cambodia. He has been an important figure in Cambodian politics since 1941.

Sihanouk was born in Phnom Penh. He became king in 1941. At that time, Cambodia was part of French Indochina. Sihanouk became a supporter of Cambodian independence. Cambodia became independent in 1953. In 1955, Sihanouk gave up the throne and was elected prime minister. He was elected head of state in 1960.

In 1970, during the Vietnam War, the prime minister, Lieutenant General Lon Nol, and Prince Sisowath Sirik Matak ousted Sihanouk and forced him into exile. Sihanouk had publicly proclaimed Cambodian neutrality in the war. But he secretly allowed North Vietnamese Communists—the enemies of the United States and South Vietnam—to establish bases in Cambodia.

In 1975, a Communist group called the Khmer Rouge gained control of Cambodia and set up a harsh political regime. Sihanouk was allowed to return to Cambodia as head of state, but he had no real political power.

In 1979, Vietnamese forces invaded Cambodia, and Sihanouk fled to China. A civil war broke out among the Khmer Rouge, the Vietnamese, and other Communist and non-Communist groups. The opposing groups signed a peace agreement in 1991 and elections were held. In 1993, a new National Assembly made Sihanouk king again. Nguyen Thi Dieu

Norris, Frank (1870-1902), was an American novelist and journalist and a leader of the naturalism movement. Norris believed that a novel should serve a moral purpose. "The novel with a purpose," he explained, "brings the tragedies and griefs of others to notice" and "prove(s) that injustice, crime, and inequality do exist."

Benjamin Franklin Norris, Jr., was born in Chicago. He moved to San Francisco with his family. While attending the University of California, he came under the influence of French naturalist writer Émile Zola and began to write *McTeague* (1899), one of his finest novels. *McTeague* tells how economic circumstances, alcoholism, heredity, and chance compel a man to become a murderer.

Norris planned a three-novel series called *Epic of the Wheat* to tell about the production, distribution, and consumption of wheat in the United States. *The Octopus* (1901) dramatizes how a railroad controlled a group of wheat farmers. The book emphasizes the control of "forces," such as wheat and railroads, over people and groups. It ranks with *McTeague* as Norris's finest work. Both novels show the author's weakness for melodrama but illustrate his genius for revealing character and writing exciting action scenes. The second book of the series, *The Pit,* was published in 1903, after Norris died following an operation for appendicitis. Alan Gribben

Norris, George William (1861-1944), was one of the great independent politicians of American public life. During his 40 years in Congress, he ignored party politics to fight for whatever he believed to be right.

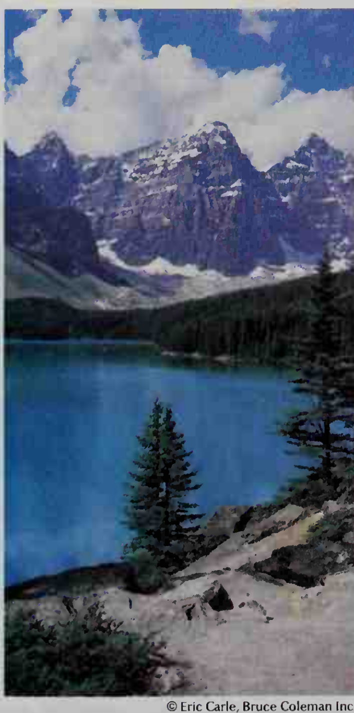
Norris was elected to the United States House of Representatives as a Republican from Nebraska in 1902. He served for 10 years. In 1910, he led the fight to reduce the power of the speaker of the House. Norris was elected a U.S. senator from Nebraska in 1912. His main interest lay in developing public ownership of utilities. He wanted the U.S. government to develop the electric power of the Tennessee River Valley, despite the policies of the Republican Party. In 1933, Congress passed his bill to create the Tennessee Valley Authority (TVA).

Norris realized the danger to the United States resulting from the rise of Nazism and Fascism in Europe. He supported aid to Britain in the early years of World War II. Norris was defeated for reelection in 1942. He was born in Sandusky County, Ohio. Robert W. Cherny

Norris-La Guardia Act of 1932 was one of the first laws that encouraged labor union activity in the United States. It restricted federal courts from issuing *injunctions* (orders) to stop union activities, including strikes, that involved no violence. The law made it impossible to enforce *yellow-dog contracts.* Many employers had forced their workers to sign such agreements, in which the employees promised not to join or aid a union. The act was sponsored by Senator George W. Norris of Nebraska and Representative Fiorello H. La Guardia of New York, both Republicans.

Before Congress passed the Norris-La Guardia Act, an employer could obtain an injunction to stop any union activity that hurt the employer's business in any way. The act banned such injunctions unless the employer had made every possible effort to settle the dispute through negotiations with the union. The act also required an employer to prove that denial of an injunction would hurt the employer more than an injunction would hurt the union. The Taft-Hartley Act of 1947 allowed injunctions in certain other cases (see **Taft-Hartley Act**).

The Norris-La Guardia Act prohibited employers from suing employees for breaking yellow-dog contracts. Employers thus could not enforce the contracts, and so eventually stopped using them. James G. Scoville



Norse mythology. See **Mythology** (Teutonic mythology).

Norsemen. See **Vikings**.

North, Lord (1732-1792), Frederick, Earl of Guilford, was British prime minister from 1770 to 1782. His shortsighted treatment of the American Colonies helped bring on the Revolutionary War (1775-1783).

North managed the House of Commons in the interests of the king, George III (see **George III**). Even when he disagreed with the king's policy, he did not oppose it. He supported the tea tax that became one of the causes of the Revolutionary War (see **Boston Tea Party**). As the war went on, North's administration became increasingly disorganized and demoralized. In 1782, he persuaded the king to accept his resignation. In 1783, he became joint secretary of state with Charles Fox but resigned after only nine months (see **Fox, Charles J.**).

North was born in London and attended Eton College and Oxford University. In 1754, his father had him elected to Parliament from a family-owned "pocket borough." He later served in the Treasury and the Privy Council. He became chancellor of the exchequer and leader of the House of Commons in 1767. John L. Bullion

North America

North America, the third largest continent in area, extends from the Arctic Ocean in the north to South America in the south. Only Asia and Africa cover larger areas. North America ranks fourth among the continents in population, after Asia, Africa, and Europe.

North America includes Canada, Greenland, the United States, Mexico, Central America, and the islands of the Caribbean Sea. Canada and the United States make up what is sometimes called Anglo-America (English-America) because many of their settlers came from England. English is the dominant language in Anglo-America. Mexico, Central America, and the Caribbean islands are sometimes called Middle America because they lie between Anglo-America and South America. Spanish is the dominant language in Middle America, though English is spoken on many Caribbean islands.

Anglo-America has valuable supplies of coal, petroleum, natural gas, and other underground resources. It has thick forests and vast farmlands. Anglo-America produces about a third of the world's manufactured goods. It also exports more food than any other region in the world. Some Middle American countries, on the other hand, have few natural resources and little level farmland. They rank among the world's poor countries.

North America offers other contrasts. Its climate is the most varied of any continent. Northern ice-covered plains differ widely in temperature from sunny Caribbean beaches. The landscape ranges from magnificent mountain peaks to flat grasslands. Luxuriant redwood forests along the Pacific coast contrast sharply with the parched sands of the southwestern deserts. North America has the world's largest island, Greenland, and the world's largest freshwater lake, Lake Superior.

John Edwin Coffman, the contributor of this article, is former Associate Professor of Geography at the University of Houston.

People

The earliest North Americans were Indians who came to the continent from Asia. Most scientists think they ar-

Facts in brief

Area: 9,347,000 mi² (24,208,000 km²). *Greatest distances* (mainland)—north-south, 4,500 mi (7,200 km); east-west, 4,000 mi (6,400 km); (including islands)—north-south, 5,400 mi (8,900 km); east-west, 5,400 mi (8,900 km). *Coastline*—about 190,000 mi (300,000 km).

Population: *Estimated 2002 population*—495,369,000; population density, 53 per mi² (20 per km²).

Elevation: *Highest*—Mount McKinley in Alaska, 20,320 ft (6,194 m) above sea level. *Lowest*—near Badwater, Death Valley, California, 282 ft (86 m) below sea level.

Physical features: *Chief mountain ranges*—Alaska, Appalachian, Cascade, Coast, Rocky, Sierra Madre, Sierra Nevada. *Chief rivers*—Arkansas, Colorado, Columbia, Fraser, Mackenzie, Mississippi, Missouri, Nelson, Ohio, Rio Grande, St. Lawrence, Yukon. *Chief lakes*—Athabasca, Erie, Great Bear, Great Salt, Great Slave, Huron, Michigan, Nicaragua, Ontario, Superior, Winnipeg. *Chief deserts*—Chihuahuan, Colorado, Great Basin, Mojave, Painted, Sonoran, Vizcaíno, Yuma. *Chief waterfalls*—Niagara, Ribbon, Silver Strand, Takakkaw, Yosemite. *Chief islands*—Cuba, Greenland, Hispaniola, Jamaica, Newfoundland, Puerto Rico, Vancouver.

Number of independent countries: 23.

rived about 15,000 years ago, but some believe they came as early as 35,000 years ago. The Indians crossed the Bering Strait—which was dry land then—while following the large mammals they hunted. They eventually settled throughout the continent, but especially in Middle America. The ancestors of today's Inuit (sometimes called Eskimos) migrated from Asia to the northern part of North America several thousand years ago.

Europeans began settling the continent in the late 1400's and early 1500's. Explorers from Spain were the first to sail across the Atlantic Ocean to Middle America. About 100 years later, British and French people settled in what are now the United States and Canada. Blacks from Africa were originally brought to North America by the Spanish to work as slaves on sugar plantations in the Caribbean. Black slaves later were brought to Atlantic coastal areas of the mainland, chiefly from British islands in the Caribbean.

Population. About 495 million people live in North America, or about 8 percent of the world's population. Few people live in the cold northern part of the continent or in its western deserts. Many large cities lie along the eastern Great Lakes, the St. Lawrence River, and the Atlantic coast from Massachusetts to Virginia. Since the 1950's, a number of people have moved from the Northeastern and Midwestern United States to California and states in the Southwest and along the Gulf coast. In Middle America, most people live in the cool highlands where the Indians originally settled. Mexico City, located in these highlands, is one of the world's largest metropolitan areas. Since 1900, many Mexicans, Puerto Ricans, and Cubans have moved to the United States.

Ancestry. Most North Americans are descendants of Europeans. Immigrants from every European country have settled in North America. More than a third of the people of the United States and nearly half of the people of Canada have ancestors from England, Ireland, Scotland, or Wales. More than a fourth of all Canadians have French ancestors. Most European ancestors of Middle Americans came from Spain.

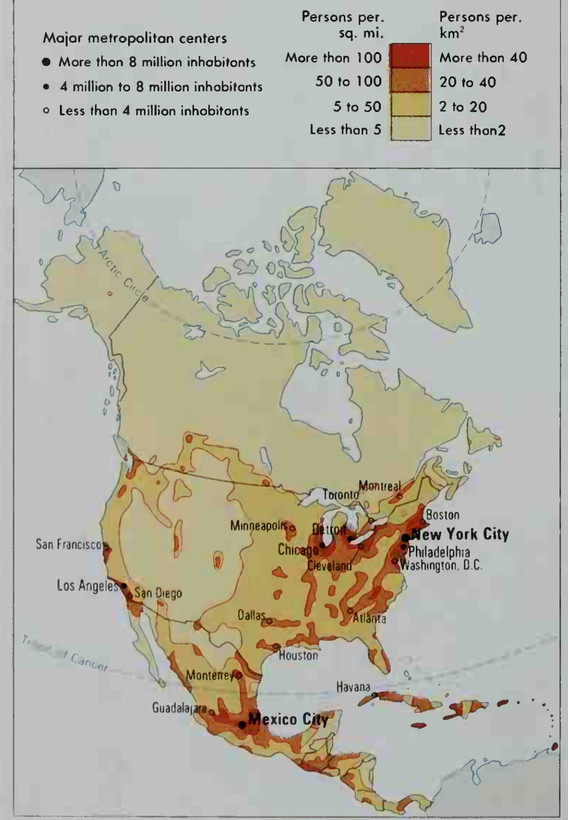
Blacks make up 12 percent of the population of the United States. Most of the people of the Caribbean islands are descended from black Africans. Other Caribbean people are *mulattoes,* people of mixed black and white descent. See **Mulatto.**

Asians make up a small percentage of the population of North America. They began immigrating to the continent in the 1800's. Asian immigrants have come mainly from China, Indochina, Japan, Korea, and the Philippines.



Many of the Indians in the United States and Canada live on reservations. Indians occupy much of central Mexico and parts of Central America. Most of the people of Mexico and Central America are *mestizos,* people of mixed white and Indian ancestry. See **Mestizo.**

There are only about 136,000 Inuit and Aleuts in North America. They live in Alaska, northern Canada, and Greenland.

Languages. Most North Americans speak English, Spanish, or French. Generally, the various regions of the continent have retained the languages of the early European colonists. English is spoken throughout the United States and most of Canada. Both English and French are spoken in Quebec and some other parts of Canada. Almost all Mexicans and most of the people of Central America and the Caribbean islands speak Spanish, though French, English, or Dutch is the language of some areas. Many Indians and Inuit still use their native languages. For more information about the people of North America, see the *People* section of the various country, state, and province articles.

Where the people of North America live

North America ranks fourth among the continents in population, after Asia, Africa, and Europe. This map shows where the people of North America live and the location of the largest cities.

WORLD BOOK map

The land

North America covers about 9,347,000 square miles (24,208,000 square kilometers), or about a sixth of the world's land area. The continent is roughly triangular in shape. The Arctic, Atlantic, and Pacific oceans border the three sides. At its northern end, North America stretches more than 5,400 miles (8,900 kilometers) from Alaska's Aleutian Islands to the Canadian island of Newfoundland. At the southern end of the continent, the narrowest parts of Panama are only about 30 miles (50 kilometers) wide. The greatest north-south distance spans about 5,400 miles (8,900 kilometers), from northern Greenland to Panama.

Land regions. North America has eight major land regions. They are (1) the Pacific Ranges and Lowlands, (2) the Western Plateaus, Basins, and Ranges, (3) the Rocky Mountains, (4) the Interior Plains, (5) the Canadian Shield, (6) the Appalachian Highlands, (7) the Coastal Lowlands, and (8) Central America and the Caribbean.

Pacific Ranges and Lowlands consist of two parallel mountain ranges that are separated by a series of valleys. The mountains extend from Alaska to Mexico. Fertile valleys between the mountain ranges are productive agricultural centers. The outer ranges include the Olympic Mountains in Washington and the coastal mountains of Oregon and California. The inland ranges have the continent's tallest peaks and some of its most spectacular scenery. Mount McKinley, North America's highest mountain, rises 20,320 feet (6,194 meters) in the Alaska Range. The inland mountains also include the Cascade Range, which features many volcanic peaks, and the Sierra Nevada of California. Much of this ruggedly beautiful area is preserved as national, state, and provincial parks.

The Western Plateaus, Basins, and Ranges lie between the Pacific ranges and the Rocky Mountains. This dry region includes the Yukon River Basin in Alaska and Canada, the Interior Plateau of British Columbia, the Colorado Plateau, the Great Basin centered in Nevada, and the Plateau of Mexico. Much of the copper, gold, lead, silver, and zinc produced in North America comes from this region. Its land features include the spectacular Grand Canyon. The lowest point in the Western Hemisphere is in Death Valley in California. It is 282 feet (86 meters) below sea level.

The Rocky Mountains form North America's largest mountain system. They run from Alaska to New Mexico, and extend southward into Mexico as the Sierra Madre Oriental. Thick forests cover the northern slopes, and the southern Rockies have rich deposits of minerals. The Rockies' scenic peaks make the region a popular recreation and tourist area.

The Interior Plains cover much of central Canada and the Midwestern United States. The eastern part of this flat, low-lying region is North America's most productive agricultural area. Corn and hogs rank among the leading products. The drier western part—the Great Plains—sup-

Tropical islands, including Aruba, *shown here,* dot the Caribbean Sea. Their beaches attract large numbers of tourists.

plies most of the continent's wheat and much of its cattle, petroleum, and natural gas.

The Canadian Shield is a huge area of ancient rock that covers most of Canada east of the Great Plains and north of the Great Lakes. Few people live in this region because of the poor soil and cold climate. Many valuable minerals lie beneath its surface. Evergreen forests spread across the southern part of the region.

The Appalachian Highlands extend from the island of Newfoundland to Alabama. The region includes low, rounded mountains; plateaus; and valleys. One of the world's most productive coal fields lies in the Allegheny Plateau, in the central part of the region. Hardwood forests grow in the northern and southern sections.

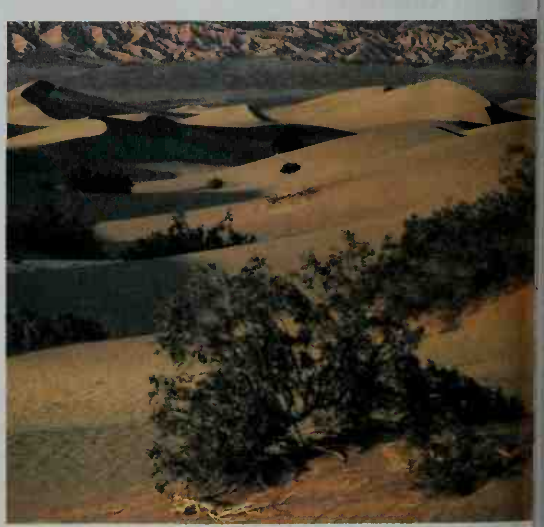
The Coastal Lowlands stretch along the Atlantic Ocean and the Gulf of Mexico, from New York City to Mexico's Yucatán Peninsula. The rich soil in much of this region creates good farmland.

Central America and the Caribbean consist of the narrow bridge of land at the southern tip of North America and the islands in the Caribbean Sea. A chain of volcanoes forms a mountainous spine along the Pacific coast of Central America. Most of the Caribbean islands were created by volcanic eruptions. Others are coral and other limestone formations.

Rivers. West of the Rocky Mountains, the rivers of North America drain into the Pacific Ocean or the Gulf of California, an arm of the Pacific. East of the Rockies, rivers flow into the Arctic Ocean, Hudson Bay, the Atlantic Ocean, or the Gulf of Mexico. The high ridge of the Rockies that separates the waters is called the Great Divide, or the Continental Divide.

West of the Rockies, such rivers as the Yukon, Fraser, and Columbia rush to the Pacific through gaps in the coastal ranges. The Colorado River cuts through the Grand Canyon as it flows toward the Gulf of California.

The Mackenzie River, which forms part of Canada's longest river system, flows from Great Slave Lake into the Arctic Ocean. Many Canadian streams and rivers empty into Hudson Bay. East of the Appalachian Mountains, several short rivers, such as the Connecticut and the Hudson, drain into the Atlantic.



The continent's longest river system, the Mississippi-Missouri-Ohio, flows into the Gulf of Mexico. This system, which is about 4,700 miles (7,600 kilometers) long, drains almost all of the United States between the Rockies and the Appalachian Mountains. The Rio Grande, which forms most of the border between the United States and Mexico, also empties into the gulf.

Lakes. Lake Superior is the largest freshwater lake in the world. It is one of the five Great Lakes, which make up part of North America's most important inland waterway. Four of the Great Lakes—Superior, Huron, Erie, and Ontario—lie on the border between Canada and the United States. The fifth, Lake Michigan, lies entirely within the United States. A chain of big lakes extends northwest from the Great Lakes to Great Bear Lake, Canada's largest lake. Utah's Great Salt Lake, one of the natural wonders of North America, is saltier than the ocean.

Waterfalls. North America's most famous waterfall is Niagara Falls, on the U.S.-Canadian border between Lake Erie and Lake Ontario. Niagara Falls consists of two waterfalls, the Horseshoe Falls and the American Falls. The Horseshoe Falls is only 167 feet (51 meters) high, but more water passes over it than over any other waterfall in North America. A number of higher falls—several more than 1,000 feet (300 meters) high—plunge through the Cascade Range and the Sierra Nevada. North America's highest waterfall, Yosemite Falls, is a main attraction at Yosemite National Park in the Sierra Nevada. Yosemite Falls drops 2,425 feet (739 meters).

Deserts. Most North American deserts lie in the southwestern United States and northern Mexico. One vast dry area reaches from southern Idaho and Oregon into Mexico. It includes the Great Basin, the Mojave Desert and Death Valley, and the Sonoran Desert. Another area, the Chihuahuan Desert, extends from southern New Mexico through western Texas into Mexico.

Coastline and islands. North America has a longer total coastline than any other continent. Including the

© Roy Morsch, Bruce Coleman I
Barren land like California's Death Valley, *shown here,* covers much of the southwestern United States and northern Mexico.

:ontinent's many islands, the coastline is about 190,000 niles (300,000 kilometers) long.

Mountains line the Pacific and north Atlantic coasts, ınd many bays cut into the rocky land. Plains slope gen- ly to the coasts along the Gulf of Mexico, the Caribbean ;ea, and the Atlantic south of New York City. There, the :oastline is relatively smooth and even.

A number of islands lie off the coasts of North Ameri- :a. Greenland is located in the North Atlantic Ocean. Al- hough Greenland is part of North America, it is gov- erned as a province of Denmark. Newfoundland and ɔther islands lie off the Canadian coast in the Atlantic Ocean. In the Pacific Ocean, Vancouver and many other slands lie off Canada, and the Aleutian Islands extend vestward from the tip of the Alaska Peninsula. The is- ands in the Caribbean Sea are called the West Indies. They include the Bahamas, the Greater Antilles, and the Lesser Antilles. Cuba, one of the Greater Antilles, is the argest Caribbean island.

Climate

North America is the only continent that has every kind of climate, from the dry, bitter cold of the Arctic to he steamy heat of the tropics. An ice sheet permanently covers the interior of Greenland, where the temperature almost never rises above freezing. In the North American *tundra,* the vast treeless plain of the far north, the temperature rises above freezing for only a short period each summer. In the low-lying areas of the far south, it is hot and rainy all the time.

Most of the rest of North America is cold in the winter and warm in the summer, with moderate precipitation. Some areas have mild winters and long, hot summers. Other areas have harsh winters and short summers. The highest temperature ever recorded in North America was 134 °F (57 °C) at Death Valley in 1913. The lowest temperature was −87 °F (−66 °C) at Northice in Greenland in 1954.

Animal life

North America has abundant animal life, which varies with the climate and plant life of each region. Caribou, musk oxen, polar bears, seals, snowy owls, whales, and wolverines live in the cold north. Jaguars, monkeys, and colorful birds are found in tropical Central America. Rocky Mountain sheep and goats graze on the slopes of the Rockies. The southwestern deserts have a wide variety of lizards and rattlesnakes. Coyotes and prong-

What North America's climate is like

Icecap: Always cold. Average monthly temperature never above freezing. Precipitation always snow.

Polar: Always cold with brief chilly summers. Little precipitation in all seasons.

Subarctic: Short cool summers and long cold winters. Light to moderate precipitation mostly in summer.

Oceanic moist: Moderately warm summers and generally cool winters. Moderate precipitation in all seasons.

Continental moist: Warm to cool summers and cold winters. Moderate precipitation in all seasons.

Subtropical moist: Warm to hot summers and cool winters. Moderate precipitation in all seasons.

Subtropical dry summer: Hot, dry summers and mild winters. Moderate precipitation in winter.

Semiarid: Hot to cold. Great changes in daily temperature except near coast. Light precipitation.

Desert: Hot to cool. Great changes in daily temperature except near coast. Very little precipitation.

Tropical wet and dry: Always hot. Both wet and dry seasons. Heavy precipitation in wet season.

Tropical wet: Always hot and always wet. Heavy precipitation well distributed throughout the year.

Highland: Because of altitude, highlands are generally cooler and wetter than adjacent areas.

WORLD BOOK map

horns—animals that are found only in North America—roam the Great Plains. The forests of Canada and the Eastern United States have beavers, black bears, deer, ermines, minks, moose, muskrats, and porcupines. Canadian geese, ducks, egrets, pelicans, and spoonbills are among the birds that winter in the marshes of the Coastal Lowlands, and alligators live in the coastal waters of the far south. Raccoons, skunks, and squirrels are common throughout the continent.

The oceans supply commercial fishing crews with valuable catches of flounder, salmon, and many other kinds of fish and shellfish. Crabs are plentiful in the northern Pacific, lobsters in the northern Atlantic, and menhaden all along the Atlantic coast. Shrimp and oysters are abundant in the Gulf of Mexico.

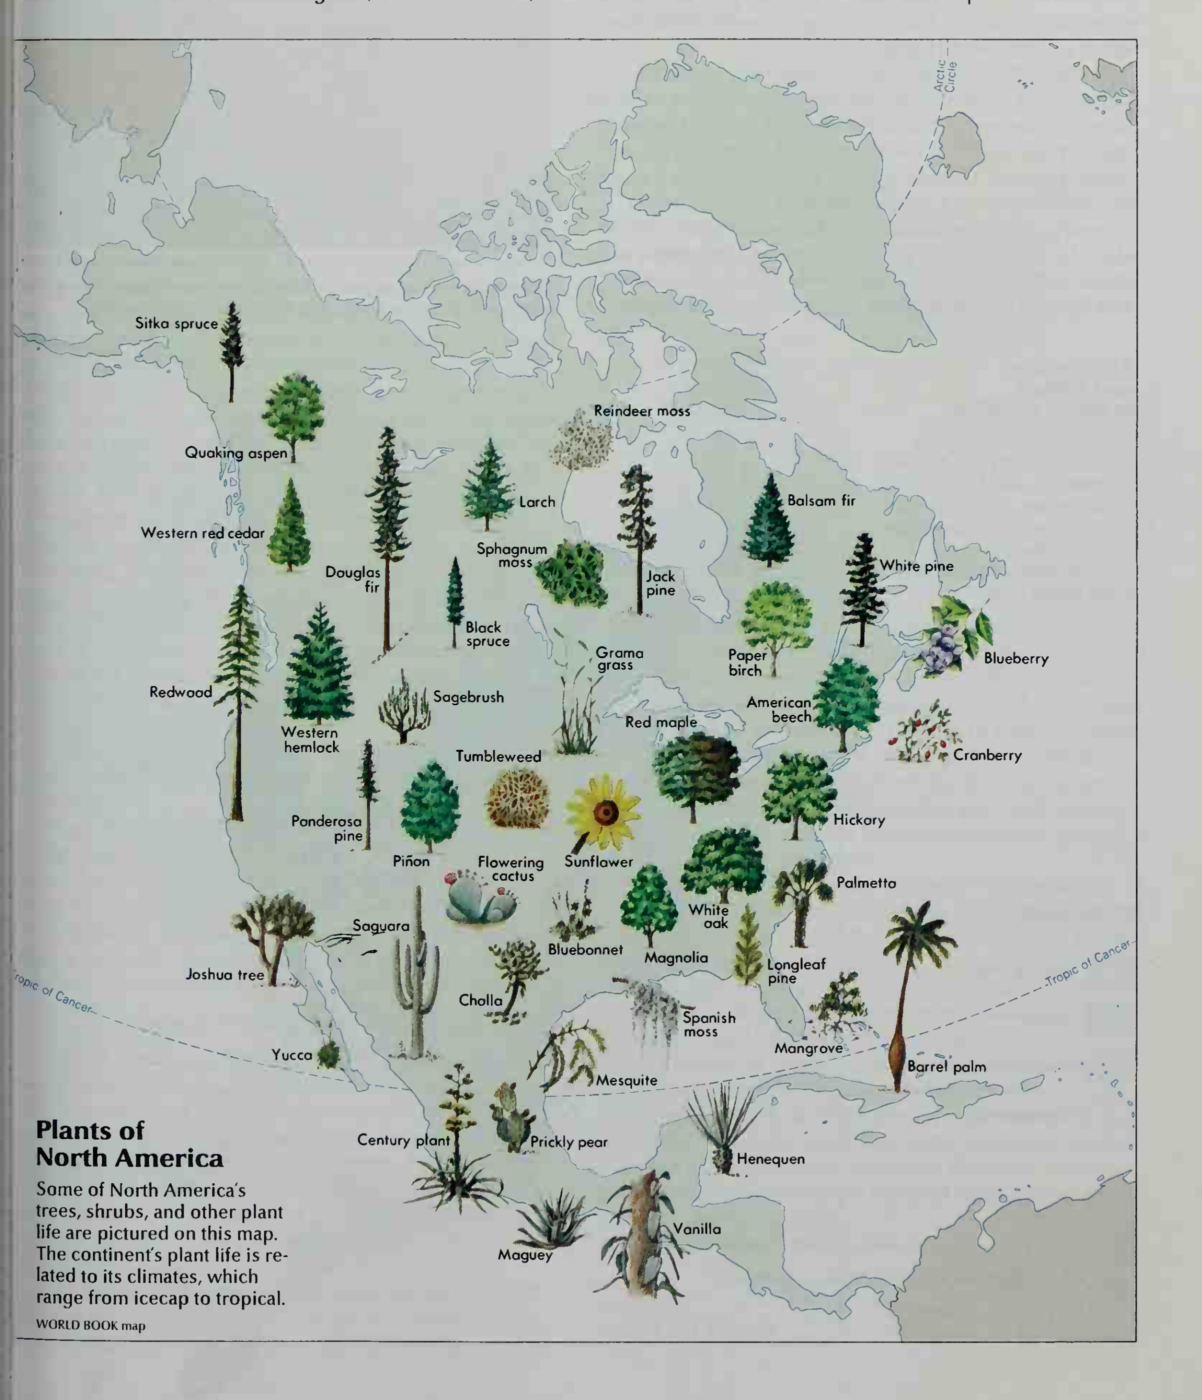
Certain kinds of wildlife have decreased sharply in number over the years. These include the bison (buffalo), the whooping crane, and the bald eagle. Game laws and the establishment of protected areas help such animals survive today.

Plant life

The plant life of North America is related to the continent's various climates. Nothing grows on Greenland's

Animals of North America

This map shows some of the many kinds of mammals, birds, and reptiles of North America. The continent's abundant animal life varies with each region's climate and plant life.



WORLD BOOK map

:ecap. Only grasses, mosses, and lichens survive in the ast cold plains that border the Arctic Ocean. A kind of ıoss called *sphagnum* or *peat* fills the marshes of the :anadian Shield and is an important export from this re- ;ion. Huge saguaro cactuses and other cactus plants ırow in the southwestern deserts. Short grasses and mall bushlike plants such as tumbleweed cover the dry ;reat Plains.

Most of the rest of the continent has forests and level ır rolling grasslands called *prairies.* The prairies stretch cross the center of the continent. The forests cover the ontinent's western mountain regions, most of Canada, and the eastern half of the United States. A tropical rain forest grows along the Caribbean coast.

The finest North American forests are those along the Pacific coast. The towering redwoods stand there, as well as forests of cedar, fir, hemlock, and spruce.

The Canadian forests include fir, larch, pine, and spruce trees. Hardwood trees such as maple and beech grow in the Northeastern United States. Many of the trees that grow in Canada and the Northeastern United States are processed into wood pulp for newsprint. Hickory, oak, and pine trees fill the forests of the Southern United States. Central America's tropical forests in-

Plants of North America

Some of North America's trees, shrubs, and other plant life are pictured on this map. The continent's plant life is related to its climates, which range from icecap to tropical.

WORLD BOOK map

clude mahogany and rosewood trees, which are used in making furniture.

Agriculture

North America ranks third among the continents after Asia and Europe in agricultural production. Its farms grow about three-fifths of the world's soybeans and about half the world's corn, flaxseed, and sorghum grain. North American farms produce about a fourth of the world's citrus fruits and oats, and a fifth of its cotton and wheat. Farmers in the United States and Canada grow so much food that large quantities may be sent to other countries. For example, North America provides about half the world's grain exports.

Fertile soil and a favorable climate help make the Midwestern United States the agricultural heart of North America. Farmers throughout this area grow corn and other crops, and they raise cattle and hogs. The Great Plains region of Canada and the United States is a major wheat-growing area. Large cattle and sheep ranches cover the Western basins and plateaus. Irrigation enables farmers in these areas to produce such crops as alfalfa, cotton, fruits, and sugar beets. Corn, dry beans, and rice are important food crops throughout Middle

© Craig Aurness, Woodfin Camp, In

Wheat fields cover much of North America's Great Plains. The continent provides about half the world's grain exports.

Agriculture and fishing in North America

This map shows the major uses of land in North America. It locates the chief agricultural products and shows the most important crops in large type. The map also shows the major fishing areas and the kinds of fish caught.

WORLD BOOK map

America. Large plantations located in the region produce such crops as bananas, coffee, cotton, and sugar cane.

Only about 4 per cent of United States and Canadian workers farm. Most of the farmers own all or at least part of their land. In Middle America, about half the people farm, and few of them own their own land. Many work as laborers on large plantations. Some own or rent small plots of land on which they struggle to grow enough food to feed their families.

Industry

Manufacturing. North America ranks second to Europe among the continents in manufacturing. Together, the United States and Canada produce about a third of the world's manufactured goods. The continent's chief manufactured goods include automobiles and automobile parts, chemical products, and food products. Manufacturing employs about a fifth of all North American workers.

The Midwestern and Northeastern United States and the Canadian provinces of Ontario and Quebec have long been North America's major manufacturing centers. Since the mid-1900's, however, industry has expanded rapidly in the Southern United States and along its Pacific coast. The chief products from factories in these newer industrial areas include aircraft and missiles, computers and electronic components, and petroleum and *petrochemicals* (chemicals made from petroleum or natural gas). Manufacturing also has grown in Middle America. Cement and fertilizer are produced throughout the region. The Bahamas and Puerto Rico produce medicines and other goods.

Mining. North America has large supplies of a broad range of minerals. The continent produces about two-fifths of the world's silver and about a third of its natural gas and nickel. North America also provides about a third of the world's supply of phosphate rock and potash, which are chiefly used to make fertilizer. About a fourth of the world's copper, crude oil, and lead comes from North America, as does a fifth of its coal. Fewer than 1 per cent of all North American workers have jobs in mining.

Most of North America's petroleum and natural gas comes from the Great Plains region, Alaska, and offshore deposits in the Gulf of Mexico. Major coal fields lie in the Appalachian Plateau, the central United States, and the Rocky Mountain region. Metallic minerals come mainly from the Canadian Shield, the Rockies and other western mountains, and the Appalachian Highlands.

Transportation and communication

North America lies between the Atlantic and Pacific oceans in the middle of the world's major trade routes. The Panama Canal at the southern tip of the continent connects the two oceans. Large ports line North America's east and west coasts. New York City, New Orleans, and Houston handle the most cargo of ports that serve the Atlantic coast. The leading ports on the Pacific Coast are Valdez Harbor, Alaska; Vancouver, B.C.; and Long Beach, Calif.

The United States and southern Canada have one of the world's most highly developed transportation systems, including inland waterways, highways, and railroads. The Mississippi River system, the Great Lakes, and the St. Lawrence Seaway form North America's most important inland waterways. Highways and railroad tracks crisscross the United States and southern Canada. Few roads lead into northern Canada. In Mexico, paved roads and railroad lines link major cities. In Central America and the Caribbean, most local roads are unpaved, and most railroad companies are small, private lines that connect sugar or banana plantations with processing plants and ports.

North America has the world's best regional airline network. Most flights serve the large cities of the United States and southern Canada. The world's busiest airports are located in the United States.

North America also has the best communications system of any continent. Radios and televisions are common in U.S. and Canadian households. Many people in Middle American countries own radios, but televisions are less widespread. About 2,000 daily newspapers are published in North America. Most North American newspapers and radio and television broadcasting stations are privately owned, except in Cuba and Nicaragua, where the government controls most communications. John Edwin Coffman

Mining and manufacturing in North America

This map shows the location of North America's chief mineral resources and manufacturing centers. Major mineral-producing areas are shown in large type, and lesser ones in small type.

North American Free Trade Agreement (NAFTA) is a pact that unites Canada, Mexico, and the United States in one of the world's largest free-trade zones. It builds on a free-trade agreement between the United States and Canada that became effective in 1989. NAFTA took effect in January 1994.

Under NAFTA, tariffs on most goods produced and sold in North America are to be gradually eliminated over 10 years. Trade of a few additional products will continue to be restricted for another 5 years. The first reductions took place in 1994.

NAFTA also establishes rights and obligations regarding trade in services, intellectual property, and international investment. These provisions could serve as models for future global and regional trade agreements.

NAFTA generated extensive opposition in the United States because of concerns that it would result in a loss of U.S. jobs. Opponents feared the job losses would result from increased Mexican imports and from a shift

n U.S. production to Mexican plants. Environmental ɲroups feared NAFTA would increase air and water pol-ution. In response to this opposition, the three coun-ries established commissions to monitor developments elated to environmental and labor issues and to help olve problems that may arise. Jeffrey J. Schott

Jorth Atlantic Treaty Organization (NATO) is a nilitary alliance consisting of the United States, Canada, nd 17 other countries. The 17 countries are Belgium, he Czech Republic, Denmark, France, Germany, Greece, Hungary, Iceland, Italy, Luxembourg, the Jetherlands, Norway, Poland, Portugal, Spain, Turkey, nd the United Kingdom.

Formed in 1949, NATO was set up largely to discour-ge an attack by the Soviet Union on the non-Commu-ist nations of Western Europe. NATO also was estab-shed to keep the peace among former enemies in Vestern Europe. After World War II ended in 1945, an ntense rivalry had developed between Communist ountries, led by the Soviet Union, and non-Communist ations, led by the United States. This rivalry became nown as the Cold War. In 1955, the Soviet Union and Communist nations of Eastern Europe formed their own nilitary alliance to oppose NATO. The Soviet-led al-ance was called the Warsaw Pact.

In forming NATO, each member country agreed to eat an attack on any other member as an attack on it-elf. Militarily, the United States was—and still is—the al-ance's most powerful member, in part because of its rge supply of nuclear weapons. The NATO countries elieved the Soviet Union would not attack Western Eu-ope if such an attack would trigger war with the United tates. NATO's policy is known as *deterrence* because it designed to *deter* (discourage) an attack. NATO's pur-ose, however, has been less clear since the Warsaw act and the Soviet Union were dissolved in 1991.

Organization. NATO has a civilian branch and a mili-ry branch. The civilian branch includes the North At-ntic Council, the highest authority in NATO. The coun-l consists of the heads of government of the NATO embers or their representatives. A secretary-general eads the council.

NATO's military branch includes three commands: Al-ed Command Atlantic, Allied Command Channel, and llied Command Europe. Allied Command Europe has aditionally functioned as the heart of NATO. NATO's ilitary commanders report to the Military Committee, hich reports, in turn, to the North Atlantic Council. The lilitary Committee consists of the military chiefs of staff other representatives of the NATO nations.

History. NATO was formed as a result of the North tlantic Treaty, which was signed by 12 countries in 949. The countries were Belgium, Canada, Denmark, ance, Iceland, Italy, Luxembourg, the Netherlands, orway, Portugal, the United Kingdom, and the United ates. Greece and Turkey joined NATO in 1952. West ermany joined in 1955. Germany replaced West Ger-any as a member in 1990, when West Germany and st Germany were united. Spain joined NATO in 1982.

During the Cold War, NATO helped maintain peace in rope through its policy of deterrence. But it also expe-enced disagreements among its members. United ates officials generally insisted that NATO rely on nu-ear weapons to deter a Soviet attack. But some people in NATO countries opposed the use of these weapons. In 1966, France pulled its troops out of the NATO mili-tary command, though it remained a NATO member. Before France withdrew its troops, NATO's central office had been in Paris. In 1967, NATO moved its headquar-ters to Brussels, Belgium.

In 1991, the Warsaw Pact was dissolved, and the Sovi-et Union broke apart into a number of independent states. Most of the states—and the Soviet Union's former allies in Eastern Europe—rejected Communism. Some people felt that without its traditional Communist ene-mies, NATO had lost its purpose and should disband. Some NATO leaders proposed offering membership in NATO to former Warsaw Pact lands. Other NATO lead-ers worried that offering membership to former Soviet allies might lead to a dangerous conflict with Russia.

To help resolve the uncertainty about NATO's future, the alliance began the Partnership for Peace program in 1994. Over 20 countries joined, including Russia. Most of the other countries that joined were Eastern Euro-pean nations. The program provides for joint military planning and exercises with NATO members but does not involve formal membership. In 1999, the Czech Re-public, Hungary, and Poland became NATO members.

In the 1990's, NATO became involved in civil wars in Bosnia-Herzegovina and Yugoslavia to stop the fighting in the two countries. NATO also entered the conflicts to stop efforts by Serbs to drive non-Serbs from most of Bosnia and from the Yugoslav region of Kosovo. In Bosnia, NATO attacked Bosnian Serb forces who were fighting the government of Bosnia-Herzegovina. The conflict ended in 1995, and NATO troops began serving as peacekeeping forces in Bosnia.

In Yugoslavia in 1999, NATO launched extensive air strikes against military targets in what became the clos-est thing to a real war ever fought by NATO. The targets included Serbian troops from the Yugoslav army who were fighting ethnic Albanian rebels in Kosovo. The bombing ended in June 1999 after Yugoslavia began withdrawing its troops from Kosovo. NATO troops then entered Kosovo as peacekeepers.

In 2001, NATO sent troops to Macedonia to help maintain a cease-fire agreement between Albanian rebels and the Macedonian government. The NATO troops were given the task of collecting and destroying the rebels' weapons.

Later that year, on September 11, terrorists crashed hijacked commercial airplanes into the World Trade Center in New York City and into the Pentagon Building near Washington, D.C. Following these incidents, NATO announced that it considered this attack on America as an attack on all NATO members.

In 2002, NATO and Russia established the NATO-Rus-sia Council. The new body allows Russia and NATO to work together on a range of projects and policies, in-cluding counterterrorism, arms control, and crisis man-agement. Gary B. Ostrower

A smoky mist rises over the Blue Ridge Mountains near Asheville. This forest-covered range, which cuts across western North Carolina, is famous for its beautiful scenery.

North Carolina *The Tar Heel State*

North Carolina leads all the states of the United States in tobacco farming and in the manufacture of tobacco products. It also leads the nation in the production of textiles and wooden furniture.

Raleigh is North Carolina's capital. Charlotte is the state's largest city.

North Carolina is a Southern state with a long coastline on the Atlantic Ocean. Islands, reefs, and sand bars make its shores some of the most treacherous in the world. Many ships have been wrecked at Cape Hatteras by the rough seas and difficult currents. Cape Hatteras is called the *Graveyard of the Atlantic.*

The state stretches westward from the coast across swamps and fertile farms. The land rises through lovely hills into industrial cities and towns. Rugged mountains cover much of the far western part of North Carolina. Mount Mitchell, which rises more than $1\frac{1}{4}$ miles (2 kilometers) above sea level, is the highest peak in the eastern United States.

Manufacturing is North Carolina's most important economic activity. Service industries are also a major part of the state's economy. The leading services include education, health care, private research, and retail trade. Research Triangle Park, a large research complex in the Raleigh-Durham area, is an important center of research for the electronics, medical, and other industries. North Carolina is a leading state in raising chickens, hogs, and turkeys. The state's main crop is tobacco. Tobacco fields, with neat rows of tobacco plants, are scattered throughout North Carolina.

In 1584, English explorers looked for a suitable site for a settlement along the North Carolina coast. As a result, the first groups of English settlers in America built colonies on Roanoke Island off the coast in 1585 and 1587. The earlier group returned to England. The later group vanished from the island, leaving behind only a myster

Birdsall, Professor of Geography at the University of North Carolina at Chapel Hill and coauthor of Regional Landscapes of the United States and Canada; *and Harry L. Watson, Professor of History at the University of North Carolina at Chapel Hill and author of* An Independent People: The Way We Lived in North Carolina, 1770-1820.

Murray and Associates, Inc.

Charlotte is the largest city in North Carolina. It serves as a major financial, transportation, and wholesaling center.

that has puzzled the ages. This group has been named the Lost Colony. Virginia Dare, the first child born to English parents in America, was a member of the Lost Colony.

During colonial days, groups of patriots in North Carolina, such as the Sons of Liberty, defied English taxes and English rule. After the Revolutionary War began in 1775, North Carolina was the first colony to instruct its delegates at the Continental Congress to vote for independence.

Before the outbreak of the Civil War (1861-1865), North Carolina tried to preserve the Union even after most other Southern states had withdrawn. But after North Carolina left the Union, it did its best to help the Confederate cause. More than 10 Civil War battles were fought on North Carolina soil. About a fourth of all Confederate soldiers killed came from North Carolina.

North Carolina's nickname, the *Tar Heel State,* refers to one of the state's earliest products—tar. According to legend, some Confederate troops retreated during a fierce Civil War battle. They left the North Carolina soldiers to fight the Union soldiers alone. The North Carolinians supposedly threatened to put tar on the heels of the other Confederate soldiers so that they would "stick better in the next fight."

Interesting facts about North Carolina

WORLD BOOK illustrations by Kevin Chadwick

Virginia Dare, the first English child to be born in America, was born on Roanoke Island on Aug. 18, 1587. Nothing else is known about her, because the colony into which she was born mysteriously disappeared.

Virginia Dare

The first state governor to be impeached was William Woods Holden of North Carolina. He had gained a reputation for waste and corruption after two years in office. On March 22, 1871, he was removed from office by vote of the state legislature.

The first operating silver mine in the United States opened in 1838 near Lexington. The mine was later named the Silver Hill Mine. It no longer operates.

The first interstate railroad opened in 1833 between Blakely, in Northampton County, and Petersburg, Va. The 75-mile (120-kilometer) Petersburg Railroad helped to increase tobacco trade from the Roanoke Valley into Virginia. The town of Blakely no longer exists, but the railroad still operates as part of the Seaboard System Railroad.

First interstate railroad

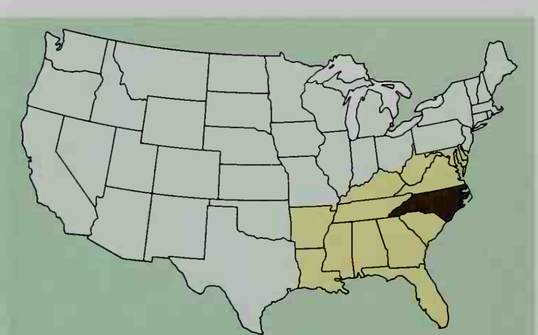
The Cape Hatteras lighthouse overlooks a part of North Carolina's Atlantic coast known for rough seas and difficult currents.

North Carolina in brief

Symbols of North Carolina

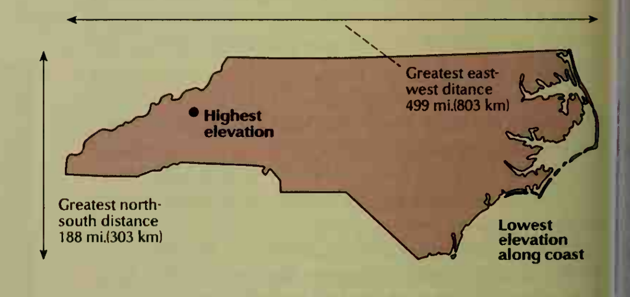


The state flag, adopted in 1885, displays two dates. May 20, 1775, is the supposed date of the Mecklenburg Declaration of Independence proclaiming Mecklenburg County's independence from Britain. On April 12, 1776, North Carolina authorized its delegates to the Continental Congress to vote for independence. The state seal, adopted in 1984, also has these dates. The standing figure represents Liberty; the seated figure, Plenty.

State flag

State seal

North Carolina (brown) ranks 28th in size among all the states and 4th in size among the Southern States (yellow).



The State Capitol is in Raleigh, North Carolina's capital since 1792. New Bern was the capital from 1766 to 1778. There was no fixed capital from 1778 to 1792.

General information

Statehood: Nov. 21, 1789, the 12th state.
State abbreviations: N.C. (traditional); NC (postal).
State motto: *Esse Quam Videri* (To Be, Rather Than to Seem).
State song: "The Old North State." Words by William Gaston; musical arrangement by Mrs. E. E. Randolph.

Land and climate

Area: 52,672 sq. mi. (136,421 km^2), including 3,954 sq. mi. (10,241 km^2) of inland water.
Elevation: *Highest*—Mount Mitchell, 6,684 ft. (2,037 m) above sea level. *Lowest*—sea level along the Atlantic Ocean.
Coastline: 301 mi. (484 km).
Record high temperature: 110 °F (43 °C) at Fayetteville on Aug. 21, 1983.
Record low temperature: −34 °F (−37 °C) at Mount Mitchell near Asheville on Jan. 21, 1985.
Average July temperature: 70 °F (21 °C).
Average January temperature: 41 °F (5 °C).
Average yearly precipitation: 50 in. (127 cm).

Important dates

1524 Giovanni da Verrazzano explored the North Carolina coast.

1585 The English established their first American colony at Roanoke Island.

c.1650 North Carolina's first permanent white settlers came to the Albemarle region from Virginia.

1765 Colonists in North Carolina began to resist enforcement of the British Stamp Act and other tax laws.

The state's official Web site at www.ncgov.com also provides a gateway to much information on North Carolina's economy, government, and history.

1789 North Carolina became the 12th state on November 21.

1835 Constitutional changes gave greater representation to the counties of western North Carolina.

1959 The Research Triangle Park, which serves industry, was opened near Durham.

1971 A new state constitution went into effect.

1989 North Carolina marked the bicentennial of its statehood.

People

Population. The 2000 United States census reported that North Carolina had 8,049,313 people. The state's population had increased 21 percent over the 1990 figure, which was 6,628,637. According to the 2000 census, North Carolina ranks 11th in population among the 50 states.

About two-thirds of North Carolina's people live in metropolitan areas (see **Metropolitan area**). Ten metropolitan areas lie entirely in North Carolina. These areas are Asheville, Fayetteville, Goldsboro, Greensboro-Winston-Salem-High Point, Greenville, Hickory-Morganton, Jacksonville, Raleigh-Durham-Chapel Hill, Rocky Mount, and Wilmington. The Charlotte-Gastonia-Rock Hill area extends into South Carolina. The Norfolk-Virginia Beach-Newport News area includes Currituck County in North Carolina. For the populations of these areas, see the *Index* to the political map of North Carolina.

Charlotte is the state's largest city, with a population of about 540,000. North Carolina's other cities with more than 100,000 people, in order of population, include Raleigh, the state capital; Greensboro; Durham; Winston-Salem; and Fayetteville. All these cities lie inland. The state's largest coastal city is Wilmington, with a population of about 76,000.

About 22 of every 100 North Carolinians are African Americans. North Carolina's other large population groups include people whose ancestors came from England, Germany, Ireland, Northern Ireland, and Scotland. A number of North Carolinians are of American Indian descent.

Schools. Churches and religious leaders controlled most of the early education in North Carolina. In 1705,

Murray and Associates, Inc

A furniture factory in Thomasville produces wooden furniture. Furniture manufacturing is a major industry in North Carolina, which leads the states in household furniture production.

Wake Forest University	Winston-Salem
Warren Wilson College	Asheville
Western Carolina University	Cullowhee
Wingate University	Wingate
Winston-Salem State University	Winston-Salem

*For campuses, see North Carolina, University of.

Charles Griffin, a schoolteacher and Anglican Church member, set up what was probably North Carolina's first school. It was at Symons Creek near Elizabeth City.

The Constitution of 1776 provided for the establishment of a public school system and for chartering the University of North Carolina. In 1795, this university became the first state university in the United States to hold classes. But North Carolina did not build its first public school until 1840. In 1901, Governor Charles B. Aycock began to improve the state's system of public education.

The State Board of Education supervises North Carolina's public school system and makes its policies. The board consists of the lieutenant governor, the state treasurer, and 11 other members who are appointed by the governor to eight-year terms. The state superintendent of public instruction, who is elected to a four-year term, serves as the chief administrator and secretary of the state board. Children from ages 7 through 15 must attend school. For the number of students and teachers in the state, see **Education** (table).

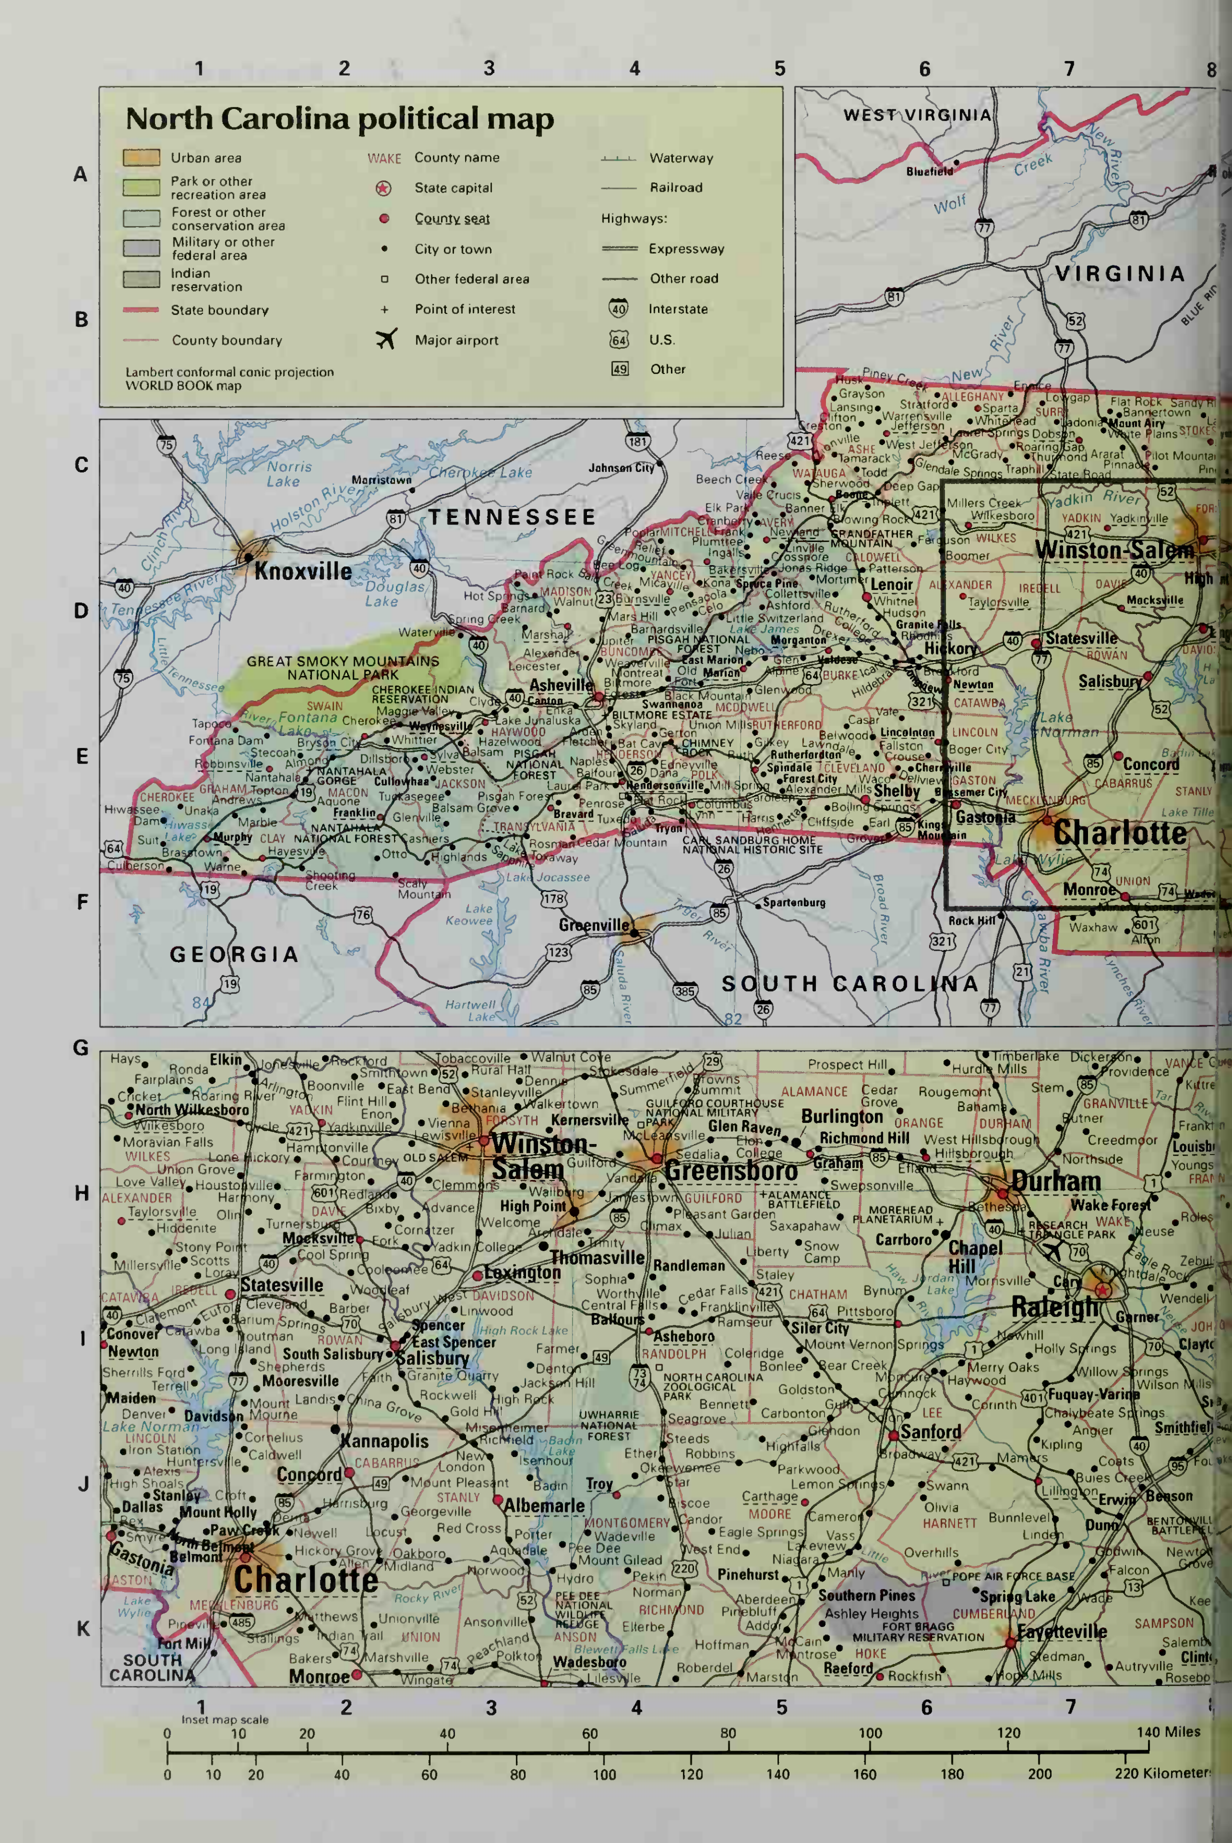
Murray and Associates, Inc.

Duke University, in Durham, is named for James B. Duke, a tobacco millionaire who gave a large endowment to the school.

Libraries. The state's first public library was founded in Bath about 1700 by Thomas Bray, an English missionary. Bray established the first free lending libraries in the American Colonies. Bath was incorporated as a town in 1705, and it became the first town in North Carolina.

In 1897, the state passed its first public-library law, and the state's first tax-supported library opened in Durham. Today, in addition to its public libraries, North Carolina has several cooperative library organizations that provide for the sharing of services and resources.

Libraries at Duke University and at the University of North Carolina at Chapel Hill own the largest collections of books in the state. Both universities have excellent collections of documents on Southern history and social sciences. The state library in Raleigh houses materials on the history of North Carolina. The archives and history division retains state records.



Museums. One of the outstanding art museums in the South, the North Carolina Museum of Art, opened in Raleigh in 1956. The University of North Carolina's art museums include the William Hayes Ackland Memorial Art Center in Chapel Hill and the Weatherspoon Art Gallery in Greensboro.

The North Carolina Museum of Natural Sciences, in Raleigh, features a large collection of specimens of prehistoric life. The Greensboro Historical Museum and the North Carolina Museum of History at Raleigh portray the history of the state.

Murray and Associates, Inc.

The North Carolina Museum of Art, in Raleigh, opened in 1956. It houses the art collections of the state, which include a collection of old master paintings.

Visitor's guide

Many Northerners come to North Carolina's sandhills area for relief from the cold winter weather. Blossoming mountain laurels, azaleas, and rhododendrons in spring and summer, and the beautiful colors of autumn, lure visitors to the mountains. Hunters track quail and deer through the mountains. Swimmers, sunbathers, and people who like fishing enjoy North Carolina's lakes, rivers, and coastlines. Historic sites, battlefields, old mansions, and beautiful gardens attract sightseers and students of American history.

One of the most popular annual events in North Carolina is the performance of *The Lost Colony.* This historical drama is staged at Fort Raleigh in Manteo during June, July, and August. The play portrays some of the hardships faced by the early English colonists who disappeared mysteriously from Roanoke Island.

The North Carolina Zoological Park near Asheboro

Chip Henderson

Places to visit

Following are brief descriptions of some of North Carolina's many interesting places to visit:

Alamance Battlefield, near Burlington, was the scene of a historic battle shortly before the Revolutionary War. About 2,000 frontiersmen, called the Regulators, rebelled against the eastern planters. The Regulators suffered heroic defeat on May 16, 1771.

Battleship *North Carolina* Memorial is located on the Cape Fear River at Wilmington. Visitors may tour the U.S.S. *North Carolina,* a famous battleship that took part in every major offensive in the Pacific during World War II (1939-1945).

Bentonville Battlefield, near Smithfield, was the scene of one of the last important Civil War battles. There, in March 1865, General William T. Sherman's Union forces defeated the Confederate troops of General Joseph E. Johnston.

Biltmore Estate covers about 8,000 acres (3,200 hectares) of forests and farmlands in Asheville. The Biltmore House, a masterpiece of early French Renaissance architecture, is the chief feature of the estate.

Cherokee Indian Reservation, at Cherokee, includes a replica of an Indian village as it looked in the 1700's. Visitors can see demonstrations of Cherokee handicraft.

Chimney Rock is a unique rock formation that towers high above the mountains in Rutherford County. Chimney Rock offers an excellent view of the Blue Ridge Mountains.

Grandfather Mountain, near Linville, looks like the huge sleeping face of an old man. Tourists may walk across a swinging bridge 1 mile (1.6 kilometers) high.

Morehead Planetarium, at the University of North Carolina in Chapel Hill, is a widely known planetarium. Spectators can watch the movements of stars and planets across a 68-foot (21-meter) dome.

Nantahala Gorge, in Swain County, plunges deep into the mountains. Indians in the region believed the gorge was haunted.

North Carolina Zoological Park, near Asheboro, has more than 700 animals and over 30,000 plants. It occupies 1,448 acres (586 hectares), making it one of the largest zoos in the world.

Ocracoke Island, a hideout of Blackbeard, the pirate, lies about 30 miles (48 kilometers) offshore, southeast of Pamlico Sound. The island was the site of many shipwrecks.

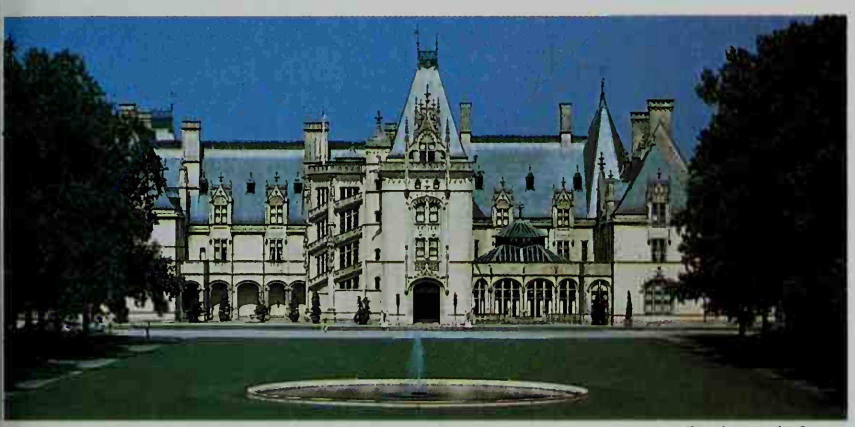
Old Salem is a restored colonial village in Winston-Salem. Moravians founded the village of Salem in 1766.

Pinehurst, a popular and charming resort village in the sandhills region, is famous for its peaceful atmosphere and its golf facilities.

Tryon Palace, in New Bern, is the restored governor's mansion originally built by William Tryon, a royal governor. American patriots defied British authority by meeting in the palace in 1774.

National parks, forests, and memorials. North Carolina has four national forests: Croatan, Nantahala, Pisgah, and Uwharrie. Several parts of Nantahala and Pisgah national forests have been set aside as national wilderness areas. North Carolina shares the Blue Ridge Parkway with Virginia, and the Great Smoky Mountains National Park with Tennessee (see **Great Smoky Mountains National Park**). The Wright Brothers National Memorial at Kill Devil Hills near Kitty Hawk honors the first powered airplane flight. For other areas, see **National Park System** (tables: National historic sites; National military parks; National battlefields; National lakeshores; National seashores).

State parks. North Carolina has 34 state parks. For information about them, write to Director, Division of Parks and Recreation, 1615 Mail Service Center, Raleigh, NC 27699-1615.



Annual events

January-March
Field Trials in Pinehurst (January); Christmas at the Homestead in Boone (January); Camellia Show in Wilmington (February); Horse Trials in Tryon (March); Moravian Easter Service in Old Salem (March or April).

April-June
Festival of Flowers at the Biltmore Estate in Asheville (April); Azalea Festival in Wilmington (April); Stoneybrook Steeplechase in Southern Pines (April); Shad Festival in Grifton (April); Ole Time Fiddler's and Bluegrass Festival in Union Grove (May); Annual Emerald Isle Beach Music Festival in Emerald Isle (May); National Hollerin' Contest in Spivey's Corner near Fayetteville (June); Summer Festival of Music in Brevard (June-August); Singing on the Mountain at Grandfather Mountain near Linville (June); Rhododendron Festival in the Bakersville area (June); The Lost Colony Outdoor Drama at Manteo (June-August).

July-September
Western North Carolina Wagon Train in Brevard (July); Bele Chere Festival in Asheville (July); Highland Games and Gathering of Scottish Clans at Grandfather Mountain (July); Mountain Dance and Folk Festival in Asheville (August); Annual Mount Mitchell Crafts Fair in Burnsville (August); State Championship Horse Show in Raleigh (September); Mule Days Celebration in Benson (September).

October-December
State Fair in Raleigh (October); National 500 Auto Race in Concord (October); Surf Fishing Tournament in Nags Head (October); Anniversary of First Powered Airplane Flight in Kill Devil Hills (December 17); Christmas at Biltmore in Asheville (December); Candlelight Christmas Tour of Historic Oakwood in Raleigh (December).

Land and climate

Land regions. North Carolina has three main land regions. These are, from east to west: (1) the Atlantic Coastal Plain, (2) the Piedmont, and (3) the Mountain Region.

The Atlantic Coastal Plain extends from New Jersey to southern Florida. North Carolina's coastal plain extends inland through an area of low, level marshland, covered by trees and water. Many swamps, shallow lakes, and rivers reflect moss-hung baldcypress trees. The Dismal Swamp in the northeast is one of the country's largest swamps. Treeless, grassy prairies cover parts of the eastern coastal plain. The western coastal plain has rich farmland. Sand hills rise along the southern part of the coastal plain.

The Piedmont is a hilly region that extends from Delaware to Alabama. In North Carolina, the Piedmont rises from about 300 feet (90 meters) at the edge of the coastal plain to about 1,500 feet (460 meters) at the mountains. The boundary between the Piedmont and the coastal plain is called the Fall Line. Along the Fall Line, rivers fall from the rocky Piedmont onto the softer, flat coastal plain. Most of the state's manufacturing industries are in the Piedmont. The area has more people than the coastal and mountain regions together.

The Mountain Region stretches from southern Pennsylvania to northern Georgia. The Blue Ridge Mountains are North Carolina's chief range. But the region also includes a number of other ranges. They include the Bald, Black, Brushy, Great Smoky, South, Stone, and Unaka ranges. All these mountains form part of the Appalachian Mountains. The Mountain Region rises from the Piedmont to heights of more than 1 mile (1.6 kilometers) above sea level. Mount Mitchell rises 6,684 feet (2,037 meters) and is the highest peak east of the Mississippi River. Forests cover much of the mountains, and the valley bottoms have good farmland. Great Smoky Mountains National Park and the Blue Ridge Parkway are in this region.

Coastline. The general coastline of the North Carolina mainland stretches 301 miles (484 kilometers). The tidal shoreline, which includes sand bars, islands, bays, and the mouths of rivers, measures 3,375 miles (5,432 kilometers). Sand bars, called the *Outer Banks,* form an almost continuous barrier along the coast. The Outer Banks jut into the Atlantic Ocean, forming Cape Fear, Cape Lookout, and Cape Hatteras. Their shifting sands have caused many shipwrecks. Cape Hatteras is called the *Graveyard of the Atlantic.*

Rivers, waterfalls, and lakes. Most of North Carolina's rivers start in the Mountain Region or in the Piedmont. They flow southeastward down the slopes of the western mountains and hills until they reach the edge of the Piedmont region. The rivers move through narrow channels above the Fall Line. Some flow through rapids where there is a noticeable drop at the Fall Line. Below the Fall Line, the rivers widen and flow slowly and then end in wide *estuaries* (river mouths). Boats can sail inland from the coast on several of the larger rivers as far west as the Fall Line.

One of the state's largest rivers, the Roanoke, flows into northeastern North Carolina, and empties into Albemarle Sound. The Neuse and Tar rivers drain the central part of North Carolina and flow into Pamlico Sound. The Cape Fear River crosses the southeastern portion of the Atlantic Coastal Plain. Several swift streams west of the Blue Ridge Mountains drain into Tennessee. North Carolina's largest dams are in this western area on the Hiwassee, Little Tennessee, and Nantahala rivers. Large dams also span the Catawba River, east of the Blue Ridge Mountains near Marion, and the Roanoke River near Roanoke Rapids.

Many lovely waterfalls add to the beauty of southwestern North Carolina. Whitewater Falls, near Brevard, plunges 411 feet (125 meters) and is one of the highest falls in the Eastern United States. North Carolina's only natural lakes are on the Atlantic Coastal Plain. Lake Mattamuskeet, the largest, is about 15 miles (24 kilometers) long and 6 miles (10 kilometers) wide.

Plant and animal life. Forests cover about 60 percent of North Carolina. Common trees include baldcypresses, hickories, maples, oaks, pines, sweet gums, tupelos, white-cedars, and yellow-poplars. In January, camellias bloom along the coastline. By April, redbud and dogwood blossoms have spread across the state. In May and June, azaleas and rhododendrons color the moun-

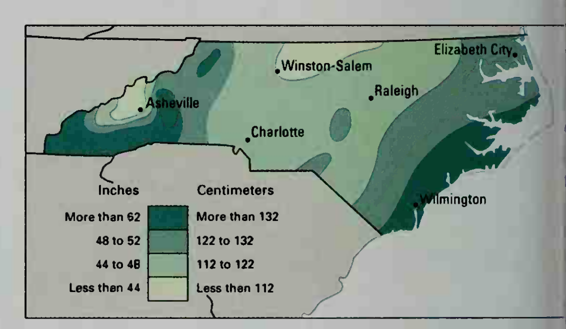
tainsides. Orchids and such insect-eaters as pitcher plants, sundews, and Venus's-flytraps flourish in the coastal savannas.

Deer are found throughout the state. Black bears live in the western mountains and in the coastal lowlands. The fields, forests, and streams are filled with beavers, foxes, gray squirrels, opossums, otters, rabbits, raccoons, and skunks. Common songbirds include cardinals, Carolina wrens, and mockingbirds. Ducks, geese, and swans winter near the coast. Mourning doves, partridges, and woodcocks inhabit much of the state.

Dolphins, marlin, menhaden, sailfish, and sturgeon are found in the waters along North Carolina's coast. Freshwater lakes and streams have bass, bluegills, crappies, sunfish, and trout.

Climate. Temperatures in southeast North Carolina average 80 °F (27 °C) in July and 48 °F (9 °C) in January. The western mountains average 60 to 70 °F (16 to 21 °C) in July, and as low as 28 °F (−2 °C) in January. The state's highest recorded temperature was 110 °F (43 °C) at Fayetteville on Aug. 21, 1983. The lowest temperature recorded was −34 °F (−51 °C) at Mount Mitchell near Asheville on Jan. 21, 1985.

Rain makes up most of the state's *precipitation* (rain, melted snow, and other moisture). The Atlantic Coastal Plain averages about 50 inches (125 centimeters) a year, the Piedmont about 47 inches (120 centimeters), and the Mountain Region about 60 inches (150 centimeters). Snowfall ranges from 40 inches (100 centimeters) a year in some mountains to only a trace in some coastal areas.



Because of the way its coastline juts into the Atlantic Ocean, North Carolina has often been the target of destructive hurricanes. The state experiences an average of one hurricane every four years.

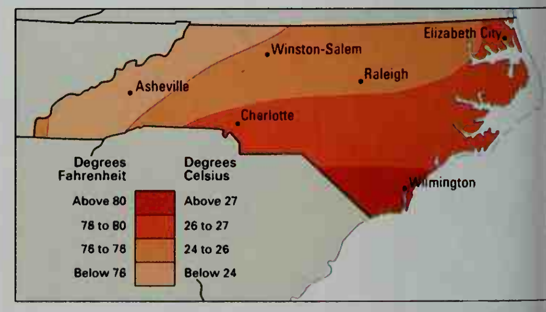
Average yearly precipitation

North Carolina has a wet climate. The far west and the area along the Atlantic Ocean receive the most precipitation. Snow is usually concentrated in the mountains of the Mountain Region.



Average January temperatures

North Carolina has short, mild winters. The southeastern part of the state has the warmest wintertime temperatures. The coolest temperatures are found in the mountainous western area.

Average July temperatures

The state has hot summers with very little variation in temperature. Generally the southeastern section of North Carolina is somewhat warmer than the area to the northwest.

WORLD BOOK maps

Economy

Service industries, taken together, account for about two-thirds of North Carolina's *gross state product*—the total value of goods and services produced in a state in a year. However, manufacturing is the single most important economic activity. It accounts for about a fourth of the gross state product. The leading manufactured goods are chemicals and tobacco products. Community, business, and personal services are the leading employer among North Carolina's service industries.

Natural resources of North Carolina include rich

soils and mineral deposits, and thick forests.

Soil. Red and yellow soils cover most of North Carolina, except along the coast and in the mountains. Light and level sandy loam soils make the central and western coastal plain the richest farmland in the state. A strip of coastal land that ranges from about 30 to 60 miles (50 to 100 kilometers) wide has marshy soils formed by dark peat or muck. Drained properly, these soils provide good farmland. Deep sandy soils cover the sand hills along the southern part of the Fall Line. The Piedmont has sandy, clay, and silt loams, mostly red in color. Strips of dark *alluvial* (water-deposited) soils lie along most of the streams. Grayish-brown loams cover most of the mountain area.

Minerals. North Carolina, sometimes called "Nature's Sample Case," has deposits of more than 300 different minerals and rocks. The mountains contain rich stores of feldspar and kaolin. The Mountain and Piedmont regions have large deposits of gneiss. Sand, gravel, and limestone are found throughout the state. The Piedmont region has clays, granite, and shale. Other mined products include phosphate rock and lithium.

Forests cover about 60 percent of the state. Oaks and pines are the most common trees. Oaks grow along with such other hardwoods as hickories, maples, and yellow-poplars over the entire state. Tupelo and sweet gum forests spread along the coastal plain rivers and streams. Loblolly pine, the state's most common softwood, grows over the entire coastal plain. Pond pine, black tupelo, baldcypress, and white-cedar are found in the swamps.

Service industries account for the largest part of North Carolina's gross state product. Most services are concentrated in the metropolitan areas.

Among North Carolina's service industries, (1) community, business, and personal services; (2) wholesale and retail trade; and (3) finance, insurance, and real estate each contribute about the same amount to the gross state product.

Community, business, and personal services employ more people than any other industry in the state. This group consists of establishments such as private health care, private schools and research facilities, motels, law firms, and repair shops. Duke University in Durham is a leading center of research for medicine and other fields. Research Triangle Park is a large research complex located in the Raleigh-Durham area. This complex is the home of many electronics and medical laboratories and specialized research facilities.

The wholesale trade of automobiles, building materials, groceries, and tobacco is important in the state. Lowe's Companies, one of the largest wholesale distributors of building materials in the United States, is headquartered in North Wilkesboro. Major retail businesses include department stores, food stores, and service stations.

Real estate businesses have benefited from the state's rapidly growing population and from the state's growing reputation as a commercial center. Charlotte is one of the country's major financial centers. Bank of America and Wachovia Corporation, two large banking companies, are based in the city.

Government ranks fourth among North Carolina's service industries. Government services include the operation of public schools, public hospitals, and military bases. North Carolina has one of the largest public university systems in the United States. Military bases in the state include Fort Bragg, Camp Lejeune Marine Corps Base, Cherry Point Marine Corps Air Station, and Seymour Johnson Air Force Base.

Transportation, communication, and utilities rank fifth among service industries. Carolina Freight, a major U.S. trucking company, is headquartered in Cherryville. Telephone companies are the major part of the communications sector. Duke Power and Carolina Power & Light are the largest utility companies in North Carolina. More information about transportation and communication appears later in this section.

Manufacturing accounts for a larger portion of the gross state product in North Carolina than it does in most other states. Goods made in the state have a *value added by manufacture* of about $83 billion a year. Value added by manufacture represents the increase in value of raw materials after they become finished products.

Chemicals rank first among North Carolina's manufactured products in terms of value added by manufacture. Pharmaceuticals and synthetic fibers are the leading chemical products. Factories in Durham, McDowell, and Wake counties make pharmaceuticals. Large plants that produce synthetic fibers operate in Enka, Kinston, Salisbury, Shelby, and Southport.

Tobacco products rank second among the state's manufactured goods. North Carolina makes more tobacco products than any other state. Factories in Greensboro, Reidsville, and Winston-Salem produce about half of the nation's cigarettes. In addition, Winston-Salem has plants that make chewing and pipe tobacco.

Textiles rank third among the state's manufactured products. North Carolina leads the United States in textile production. North Carolina has about 720 textile plants. Gaston County cotton mills spin more yarn than any other U.S. county. North Carolina makes about half the nation's hosiery. Greensboro has the world's largest mill for weaving denim. Other textile products made in

Production and workers by economic activities

Economy of North Carolina

This map shows the economic uses of land in North Carolina and where the state's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

North Carolina include carpeting, synthetic fabric, and household textiles, such as sheets and towels.

Computer and electronic products are fourth in terms of value added. Communications equipment and computer components are the leading electronic products.

Other products manufactured in North Carolina include food products, furniture, machinery, and rubber and plastic products. Baked goods, beverages, and meat products are the leading food products. North Carolina leads the states in the production of household furniture, and High Point is often called the *Furniture Capital of America.* Factories in many towns produce wooden furniture. Important types of machinery made in North Carolina include construction equipment, industrial machinery, and refrigeration equipment. Various plastic products are made throughout the state.

Agriculture. Farmland covers about 30 percent of North Carolina. The state has approximately 58,000 farms. Livestock products and crops each provide about half of North Carolina's agricultural income.

North Carolina ranks among the leading states in both chicken production and hog production. Hogs provide the most income of all livestock products in the state. Most hogs are raised in the eastern part of the state. *Broilers* (chickens from 5 to 12 weeks old), are the second most valuable livestock product. The largest number of broilers come from Chatham, Moore, Randolph, and Union counties.

North Carolina raises more turkeys than any other state. Duplin, Sampson, Union, and Wayne counties raise the most turkeys. Dairy farming is important in the western part of the state. Other livestock products in North Carolina include beef cattle, eggs, and ducks.

Tobacco is North Carolina's leading crop. Fire-cured tobacco is grown in many parts of the state. More fire-cured tobacco is sold in Wilson than in any other city in the United States. Burley tobacco is grown in mountainous areas near Asheville. Corn and soybeans also rank as important crops. Both grow in the eastern part of the state, and both are used largely for livestock feed. Soybeans are also used to make oil.

North Carolina is a leading state in growing peanuts and sweet potatoes. Peanuts grow chiefly in the northern coastal plain. Sweet potatoes grow in the warm, humid regions of the western coastal plain. Apples are the leading fruit crop. Blueberries, peaches, and strawberries are also important. North Carolina's other agricultural products include cotton, greenhouse and nursery products, hay, trees, and wheat.

Mining. Crushed stone, mainly granite, is North Carolina's leading mined product. Limestone and traprock are also mined from the state's quarries.

Other leading mined products of North Carolina are phosphate rock and sand and gravel. Phosphate rock is mined in Beaufort County. It is used to make fertilizers. Sand and gravel, used in construction and glassmaking, are produced mainly in the coastal plain.

North Carolina is a leading producer of feldspar, mica, and pyrophyllite. The state's other mined products include clays, granite, marble, olivine, and talc.

Fishing industry. North Carolina's annual fish catch is valued at about $100 million. The most valuable fish and shellfish caught are blue crabs, clams, flounder, shrimp, and trout. The Beaufort-Morehead City area is a leading U.S. fishing port. North Carolina's *aquaculture* industry raises catfish, crayfish, Atlantic menhaden, and trout in natural and artificially created bodies of water.

Electric power. About two-thirds of the electric power used in North Carolina is generated within the state. Most of the rest is generated in South Carolina. Of the power generated within North Carolina, about 60 percent comes from power plants that burn coal. Nuclear plants provide about 35 percent. Most of the remaining power comes from hydroelectric plants.

Transportation. Rivers served as the first highways in North Carolina. Roads began to appear in the 1700's but most remained poor until well into the 1900's. The state began a major campaign to improve its roads in the 1920's. The first two major railroads—the Wilmington and Raleigh, and the Raleigh and Gaston—began service in 1840. At that time, the 161-mile (259-kilometer) Wilmington line was the longest in the world.

Today, seven interstate highways link North Carolina's ies. Many bridges span inlets and rivers along the ite's coast. About 25 rail lines provide freight service, d passenger trains serve 18 cities. The state's busiest port is at Charlotte. The Raleigh-Durham area and eensboro also have major airports. Harbors at More- ad City, Southport, and Wilmington are part of the At- ıtic Intracoastal Waterway (see **Atlantic Intracoastal aterway**).

Communication. James Davis, a printer and editor, tablished North Carolina's first newspaper, the *North ırolina Gazette,* at New Bern in 1751. The weekly *Raleigh Register* was founded in 1799. The state's largest daily newspapers today are the *Charlotte Observer* and *The News and Observer* of Raleigh. North Carolina publishers print about 220 newspapers, of which about 50 are dailies, and about 150 periodicals.

North Carolina's oldest radio station, WBT of Charlotte, began broadcasting in 1922. Television in the state started in 1949, with stations WBTV in Charlotte and WFMY in Greensboro. Today, North Carolina has about 420 radio stations and 40 television stations. Cable television systems and Internet providers serve a large number of North Carolina communities.

Government

Constitution of North Carolina became effective in 71. The state had two earlier constitutions, adopted in 76 and 1868. Amendments to the Constitution can be oposed in the state legislature or by a constitutional nvention. An amendment proposed in the legislature ust be approved by three-fifths of both houses. Then it ust be approved by a majority of the voters in a gener- election. A constitutional convention must be ap- oved by two-thirds of both houses, and by the voters, fore it can meet to propose and adopt amendments the Constitution.

Executive. North Carolina's governor and lieutenant ›vernor serve a four-year term and may be reelected ıly once. The governor can appoint a number of im- ›rtant state officials, including the heads of nine execu- e departments. The voters elect eight other top ad- inistrative officers to four-year terms. They are the torney general, auditor, secretary of state, superin- ndent of public instruction, treasurer, and commis- ›ners of agriculture, labor, and insurance. These offi- ıls and the lieutenant governor make up the council of ıte, an advisory council to the governor.

Legislature of North Carolina is called the General ssembly. It consists of a 50-member Senate and a 120- ember House of Representatives. Senators are elected ›m 42 senatorial districts. Representatives are elected ›m 98 representative districts. Members of both hous- serve two-year terms. The lieutenant governor is esident of the Senate. The House of Representatives ects a speaker to preside over it. The legislature meets ery year. In odd-numbered years, it has a regular ses- ›n that begins on the Wednesday after the second onday in January. In even-numbered years, a short ssion is held, usually in June, to review financial mat- rs and conclude any business from the previous year.

In 1965, a federal court ordered North Carolina to re- aw its legislative districts to provide equal representa- ›n. The General Assembly reapportioned the districts 1966. The legislative districts were reapportioned ıain in 1971, 1982, 1984, 1991, and 1997.

Courts. North Carolina's court system has three divi- ›ns: an appellate division, a superior court division, d a district court division. The appellate division con- ts of the Supreme Court, the state's highest court; and e court of appeals, an intermediate appellate court. ıe appellate courts hear cases appealed from lower ›urts. The Supreme Court has a chief justice and 6 as- ciate justices, and the court of appeals has 12 judges.

The superior and district court divisions consist of 60 judicial districts. Each district is served by one or more superior court judges who hear civil and criminal trials. Each district also has two or more district court judges who handle minor civil and criminal cases.

Supreme court justices, court of appeals judges, and superior court judges are elected to eight-year terms. District court judges are elected to four-year terms. If any leaves office, the governor appoints a successor.

Local government. North Carolina has 100 counties. Each county is governed by a board of county commissioners. The boards consist of three to seven members, elected to two- or four-year terms, depending on the county. They meet monthly to supervise county affairs, and to perform such duties as appropriating funds and levying taxes. County officials include the sheriff, register of deeds, superior court clerk, county manager, finance officer, attorney, and tax officials.

State laws grant cities and towns *home rule* (self-government) to the extent that they may make certain amendments to their charters. But supervision and control remain in the hands of the General Assembly. North Carolina has more than 500 incorporated municipalities. An area may incorporate by petitioning the General Assembly. Most of the larger cities have the council-manager form of government. Other forms of municipal government are mayor-council and commission.

Revenue. Taxes account for about 55 percent of the state government's *general revenue* (income). Federal grants and other U.S. government programs make up most of the rest. A personal income tax provides the greatest portion of the tax revenue. Other important tax revenue sources in North Carolina include a general sales tax and taxes on motor fuels, corporate income, and public utilities.

Politics. The Democratic Party traditionally has dominated the state's politics. But Republicans have gained strength since the mid-1960's. From the Reconstruction period (1865-1877) through 1964, the Republican presidential candidate won the state's electoral votes only in 1928. But since 1968, the Republican has won in all of the presidential elections except 1976. For North Carolina's voting record in presidential elections, see **Electoral College** (table). In 1972, James E. Holshouser, Jr., became the first Republican to be elected governor of North Carolina since 1896. Also in 1972, Jesse A. Helms became the first Republican elected to the U.S. Senate from the state since 1895.

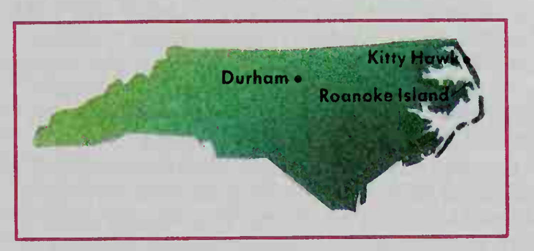
† Provisional governor

History

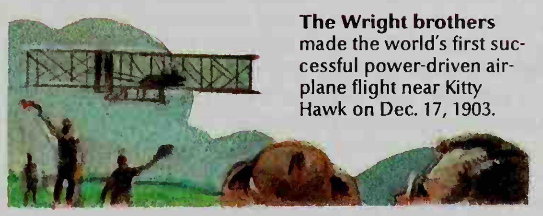
Indian days. About 35,000 Indians, belonging to about 30 tribes, lived in the North Carolina region when Europeans first arrived. The most important tribes were the Cherokee in the western mountains; the Hatteras along the coast; and the Catawba, Chowanoc, and Tuscarora of the coastal plain and the Piedmont.

Exploration and settlement. Giovanni da Verrazzano, sailing in the service of France, was the first known European to explore the North Carolina coast. He visited the Cape Fear area in 1524. Verrazzano sent glowing reports of what he saw to King Francis I of France. But the king was not interested in colonizing the region. Two years later, an expedition led by Lucas Vásquez de Ayllón of Spain may have stopped near Cape Fear to scout for a place to settle. Vásquez and his followers decided the area was unsuitable, and the expedition moved farther south to settle on the coast of South Carolina or Georgia. In 1540, Hernando de Soto of Spain led an expedition over the mountains at the southwestern tip of the North Carolina region. He hoped to find gold. Instead, he became the first European to reach the Mississippi River. He arrived at the river in 1541. Other Spaniards also came to the region, but neither they nor the French established any permanent settlements.

In 1584, Sir Walter Raleigh of England sent explorers to the North Carolina coast to find a suitable site for a settlement. The next year, the first English colony in America was established on Roanoke Island. But misfortunes forced the settlers to return to England in 1586. Raleigh sent a later expedition to Roanoke Island in 1587, with John White as governor. White established a colony and sailed back to England for supplies that same year. When Queen Elizabeth allowed White to return to Roanoke Island in 1590, his colony had disappeared. No one knows what happened to the more than a hundred men, women, and children of what has come to be called the Lost Colony (see **Lost Colony**).



In 1629, King Charles I of England granted his attorney general, Sir Robert Heath, the southern part of the English claim in America. This included a strip of land containing what is now both North Carolina and South Carolina, and extending to the Pacific Ocean. The land was named the Province of *Carolana* (land of Charles). Heath's attempts at settlement failed.

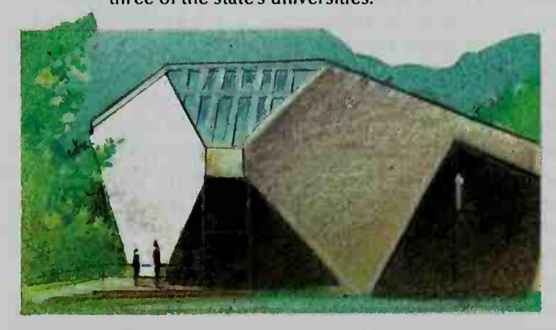


The first permanent European settlers in Carolina came from Virginia. They settled in the Albemarle Sound region around 1650. In 1663, Charles II of England regranted Carolina to eight of his favorite nobles. He made them *lords proprietors* (ruling landlords). These men divided Carolina into three counties: (1)

Historic North Carolina

The Lost Colony was a group of more than 100 colonists that settled on Roanoke Island in 1587. Three years later, a supply ship found the colony had disappeared. One of its only traces was the word *Croatoan* carved on a tree.

The Wright brothers made the world's first successful power-driven airplane flight near Kitty Hawk on Dec. 17, 1903.



The Sons of Liberty led demonstrations against a series of taxes imposed by England before the Revolutionary War.

The tobacco industry grew rapidly in North Carolina after the Civil War. Tobacco factories in the state numbered nearly 130 by 1880.

The North Carolina Research Triangle Park, built to serve industry, opened near Durham in 1959. The research center is run by three of the state's universities.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in North Carolina

1524 Giovanni da Verrazzano, a Florentine explorer sailing for France, visited the North Carolina coast.

1585 The English established at Roanoke Island their first colony in what is now the United States.

1629 King Charles I of England granted *Carolana* to Sir Robert Heath.

1650? The first permanent settlers came to the Albemarle region from Virginia.

1663 King Charles II granted the Carolina colony to eight lords proprietors.

1664 North Carolina's first permanent government was established in Albemarle County.

1711 The Tuscarora Indians attacked settlements between the Neuse and Pamlico rivers. The colonists defeated the Indians in 1713.

1729 North Carolina came under direct royal rule.

1765 Colonists in North Carolina began to resist enforcement of the British Stamp Act and other tax laws.

1774 North Carolina sent delegates to the First Continental Congress in Philadelphia.

1776 The Whigs defeated the Tories at Moore's Creek Bridge. North Carolina adopted its first constitution.

1781 British forces withdrew from North Carolina and surrendered in Virginia.

1789 North Carolina ratified the Constitution and became the 12th state on November 21.

1835 Constitutional changes gave greater representation to the counties of western North Carolina.

1861 North Carolina seceded from the Union.

1865 General Joseph E. Johnston surrendered to General William T. Sherman near Durham.

1868 North Carolina was readmitted to the Union.

1901 Governor Charles B. Aycock began a campaign to improve North Carolina public schools.

1903 The Wright brothers made the first successful powered airplane flight near Kitty Hawk.

1915 The state legislature set up a highway commission.

1933 The state took over the support of public schools.

1949 The people approved a large bond issue for road and public-school construction.

1950 Great industrial expansion began.

1959 The North Carolina Research Triangle Park, operated by three of the state's universities to serve industry, opened.

1960 Four black students launched the sit-in movement at a lunch counter in Greensboro.

1971 A new state Constitution went into effect.

1972 James E. Holshouser, Jr., became the first Republican to be elected governor of North Carolina since 1896.

1989 North Carolina marked the *bicentennial* (200th anniversary) of its statehood.

Albemarle, in the northern part; (2) Clarendon, in the Cape Fear region; and (3) Craven, in what is now South Carolina. In 1664, William Drummond was appointed governor of Albemarle County, and government began in Carolina. Clarendon County lasted only until 1667. From then until 1689, Albemarle County had the only government in the North Carolina region.

Colonial days. The colonists of Albemarle County believed that the proprietors and governors were more interested in making money than in governing wisely. In 1677, some Albemarle colonists revolted against their governor. They ran the county for over a year by themselves. The revolt became known as Culpeper's Rebellion after John Culpeper, one of the leaders of the uprising. Between 1664 and 1689, the colonists drove five Albemarle governors from office.

After 1691, governors were appointed to govern the entire Carolina colony, with a deputy governor for the North Carolina region. The deputy governors ruled wisely and the colonists accepted them. The North Carolina region became a separate colony in 1712.

During the late 1600's and early 1700's, increasing numbers of settlers came to North Carolina. In 1705, North Carolina's first town, Bath, was incorporated near the mouth of the Pamlico River. By 1710, settlements had spread down the coast and along the riverbanks as far south as the Neuse River. In 1710, Swiss and Germans founded New Bern, a community several miles inland on the Neuse, in Tuscarora Indian territory. At dawn on Sept. 22, 1711, enraged Tuscarora Indians, whose land had been seized by European settlers, attacked New Bern and other settlements. Within two hours, most of the settlements between the Neuse and Pamlico rivers lay in ruins. The Indians had massacred hundreds of settlers, burned their homes, stolen their valuables, and destroyed their crops. The massacre marked the beginning of the Tuscarora War, the worst Indian war in North Carolina's history. The colonists defeated the Indians on March 25, 1713.

While settlers battled the wilderness and the Indians during the late 1600's and early 1700's, pirates terrorized North Carolina's coastline. Most piracy along the Atlantic Coast ended with the death of the pirate Blackbeard in a battle near Ocracoke Island in 1718.

In 1729, the lords proprietors sold their land back to the king of the United Kingdom. North Carolina became a royal colony, ruled by royal governors named by the king. The governors ruled wisely and helped the colony grow. In 1729, only about 36,000 people lived in North Carolina, mostly along the coast. By 1775, the population had grown to nearly 350,000, and settlement had spread westward across the Piedmont and into the mountains.

North Carolina contributed money and troops to help the United Kingdom fight several colonial wars. Those wars included Queen Anne's War (1702-1713), King George's War (1744-1748), and the French and Indian War (1754-1763). In 1760, Hugh Waddell of Wilmington led North Carolina troops to an important victory over the Cherokee Indians at Fort Dobbs, near present-day Statesville. In 1761, the Cherokee signed a peace treaty that opened a vast area of western Virginia and the Carolinas to settlement. See **French and Indian wars.**

Revolution and independence. The United Kingdom placed additional taxes on the American Colonies to help pay for the colonial wars. But the colonists objected to taxes levied without their consent. Protestors in North Carolina and other colonies called the Sons of Liberty led demonstrations and even armed rebellions against these taxes. Meanwhile, some farmers in western North Carolina rose up against the high taxes and dishonest officials forced upon them by the wealthy eastern planters. The western rebels were called the Regulators. William Tryon, the royal governor, needed more than a thousand troops to defeat the Regulators at the Battle of Alamance on May 16, 1771.

North Carolina sent delegates to Philadelphia to attend the First Continental Congress in 1774. After the Revolutionary War began in April 1775, North Carolinians quickly took sides. Those who opposed the British were called Whigs. Those who remained loyal to the king were called Tories. On Feb. 27, 1776, Whig forces, under Colonels Richard Caswell and Alexander Lillington, crushed the Tories in the Battle of Moore's Creek Bridge. This was the first battle of the Revolutionary War in North Carolina. The Whig victory prevented a planned British invasion of North Carolina. On April 12, 1776, North Carolina became the first colony to instruct its delegates to the Continental Congress to vote for independence. Later that year, North Carolina adopted its first constitution and chose Caswell as governor. On July 21, 1778, North Carolina *ratified* (approved) the Articles of Confederation.

Much of the Revolutionary War was fought outside North Carolina's borders. But North Carolinians joined the fight against the British in Virginia, Georgia, and South Carolina. Inside the state, warfare between Whigs and Tories produced much bloodshed and bitterness. In 1780, British forces led by Lord Charles Cornwallis marched toward North Carolina from the south. Part of Cornwallis's army was slaughtered in the Battle of Kings Mountain, just south of North Carolina. But after a retreat, Cornwallis moved northward again, this time into North Carolina. On March 15, 1781, Cornwallis's troops outlasted the American General Nathanael Greene's forces in the Battle of Guilford Courthouse. But the severely weakened British abandoned North Carolina soon afterward.

Statehood. North Carolinians delayed approving the United States Constitution because they opposed a strong federal government. At the Hillsborough Convention of 1788, they rejected the Constitution and suggested many amendments to it. The Bill of Rights to the Constitution, proposed by Congress in 1789, included some of these suggestions. North Carolina finally ratified the Constitution on Nov. 21, 1789.

During the early 1800's, North Carolina was a backward state. It had little commerce or industry. It lacked seaports and transportation facilities. North Carolina planters relied heavily on slave labor, and black slaves made up about a third of the population. Many people left North Carolina, including three men who later became president—Andrew Jackson, James K. Polk, and Andrew Johnson.

North Carolina began to progress in 1835, after revising its Constitution. The new Constitution gave greater representation to the people of the western region and encouraged the development of that area. Public schools, railroads, and roads were built. Agriculture in-

creased, and manufacturing started to grow. North Carolina led the nation in gold production until the California Gold Rush of 1849.

The Civil War and Reconstruction. Although North Carolina was part of the South, it tried to preserve the Union even after most other Southern states had *seceded* (withdrawn). The Civil War began on April 12, 1861. When President Abraham Lincoln asked for troops to fight the Confederate States, North Carolina refused. The state seceded from the Union on May 20, 1861.

Union forces captured much of North Carolina's coastline early in the war. But the port at Wilmington remained open to Confederate supply ships until January 1865. More than 10 battles took place in North Carolina. The bloodiest of these was fought at Bentonville from March 19 to 21, 1865. There, Union forces under General William T. Sherman defeated the Confederate troops of General Joseph E. Johnston. Johnston surrendered to Sherman near Durham on April 26. North Carolina supplied 125,000 men to the Confederate cause. About a fourth of all the Confederate soldiers killed came from North Carolina. However, many North Carolinians sympathized with the Union and resisted the Confederacy.

During the Reconstruction period, federal troops supervised the state's government until 1868. That year, a new state Constitution abolished slavery and gave blacks the right to vote. The Republican Party then gained control of North Carolina. Its members included blacks, white Union sympathizers, and a few Northerners called *carpetbaggers* (see **Carpetbaggers**). The state rejoined the Union on June 25, 1868.

During the Reconstruction years, bitter struggles took place between Republicans and Democrats, and between blacks and whites. The Ku Klux Klan and other secret groups supported white supremacy and tried to keep blacks from voting. Democrats gained control of the state legislature in 1870. They impeached Republican Governor William W. Holden in 1871, and removed him from office. In 1875, the Democratic legislature added 30 amendments to the Constitution, thus ensuring white, Democratic control of county government.

Economic progress. The Civil War had brought death and destruction to North Carolina. But it also freed about 350,000 of the state's black slaves. After slavery was abolished, North Carolina planters divided their land into small farms. They rented these farms to tenants in return for a share of the crop. Under this system of *sharecropping,* the number of farms in the state grew from about 75,000 in 1860 to 150,000 in 1880.

The people of North Carolina rebuilt their state quickly. By the 1880's, farm production equaled what it had been before the war. Tobacco and cotton crops led the growth. Industry also grew rapidly. Many new cotton mills opened. Tobacco-manufacturing and furniture-making also became large-scale industries. Industrialist James Buchanan Duke built up the American Tobacco Company until it had eliminated most competition. Farmers left the farms for industrial jobs in the cities.

In 1898, the Democrats won control of the state legislature in a campaign based on racial hatred. They amended the state Constitution to deprive most blacks of voting rights. New laws required the racial segregation of schools, restaurants, railroad trains, streetcars, and other public facilities.

The early 1900's. In 1901, Governor Charles B. Aycock started a far-reaching program to improve North Carolina's public education system. In 1915, the legislature created the State Highway Commission, which began the largest roadbuilding program in the state's history. That program earned North Carolina the nickname of the "Good Roads State" during the 1920's.

The state's industries developed at a tremendous rate during the early 1900's. By the late 1920's, North Carolina led the nation in the production of cotton textiles, tobacco products, and wooden furniture.

The Great Depression of the 1930's brought sudden drops in prices and wages. Businesses failed and banks closed. Workers lost their jobs and farmers lost their farms. The federal and state governments tried to fight the effects of the depression. The North Carolina government reduced local taxes and took control of all highways and public schools. Federal control of agricultural production raised farm prices and income. The state passed welfare measures, raised teachers' salaries, and reduced working hours to help North Carolina out of the depression by the late 1930's.

The mid-1900's. During World War II (1939-1945), North Carolina mills supplied the armed forces with more textiles than any other state. Its mines supplied more than half the mica used in U.S. war production.

In the late 1940's, North Carolina built new hospitals and mental health facilities, and it paved many roads in rural areas. Two dams increased the state's power output. Fontana Dam, at the edge of the Great Smoky Mountains, started operating in 1945, and Kerr Dam, near Henderson, went into operation in 1954.

North Carolina blacks began to gain greater rights during the mid-1900's. A key event occurred in 1954, when the Supreme Court of the United States ruled that compulsory school segregation was illegal. In 1960, four black students remained seated at a restricted lunch counter in Greensboro after they were refused service. Their action sparked a wave of sit-in demonstrations throughout the South. Such protests contributed to the passage of the Civil Rights Act of 1964, which banned the segregation of public facilities.

During the 1950's, North Carolina continued to shift from a rural, agricultural economy to an urban, industrial economy. The state worked to attract new industries by providing businesses with technical and engineering assistance and by reducing taxes on corporations. In 1956, three universities—Duke University at Durham, North Carolina State University at Raleigh, and the University of North Carolina at Chapel Hill—combined their research resources. They helped form the North Carolina Research Triangle Park, a research center that serves industry. The center opened in 1959.

In 1963, the legislature set up a system of community colleges and technical institutes. Also in 1963, the state adopted a single university plan for the University of North Carolina, beginning with campuses at Chapel Hill, Greensboro, and Raleigh. By 1972, the University of North Carolina had 16 campuses. These included the North Carolina School of the Arts, which had become the nation's first state-supported school for the arts when it opened in Winston-Salem in 1965.

The late 1900's. In 1971, in a case involving a Charlotte school district, the Supreme Court of the United

States ruled that children could be bused to achieve racial integration. Most North Carolina school districts were integrated soon afterward. The Charlotte busing program became a model for the rest of the country.

The Republican Party increased its strength in the state in the late 1900's. In 1972, James E. Holshouser, Jr., became the first Republican to be elected governor of North Carolina since 1896. Also in 1972, Jesse A. Helms became the first Republican candidate to be elected to the United States Senate from North Carolina since 1895.

The development of Research Triangle Park brought prosperity to Durham, Raleigh, Chapel Hill, and the surrounding area. In the late 1980's and the 1990's, many of North Carolina's urban areas experienced growth in the finance and technology industries. However, employment in many traditional industries, including tobacco and textiles, declined. During the 1980's and the 1990's, North Carolina experienced growth in agricultural-related businesses, such as hog, poultry, and sweet potato production. The filmmaking industry also flourished. Population growth in the state's urban areas increased demand for better schools, highways, health care facilities, and other government services.

Recent developments. In 1999, school busing was discontinued in the Charlotte school district. A federal judge ruled that forced integration was no longer necessary because all traces of intentional discrimination had disappeared.

In September 1999, North Carolina suffered one of the worst natural disasters in its history. Hurricane Floyd's floodwaters left drowned livestock and flooded farms and towns all across the eastern part of the state. Officials estimated the damage costs of the storm to be billions of dollars. Stephen S. Birdsall and Harry L. Watson

University of North Carolina

le **University of North Carolina at Chapel Hill** is the oldest titution in the university system. It includes the Louis Round lson Library, *above.*

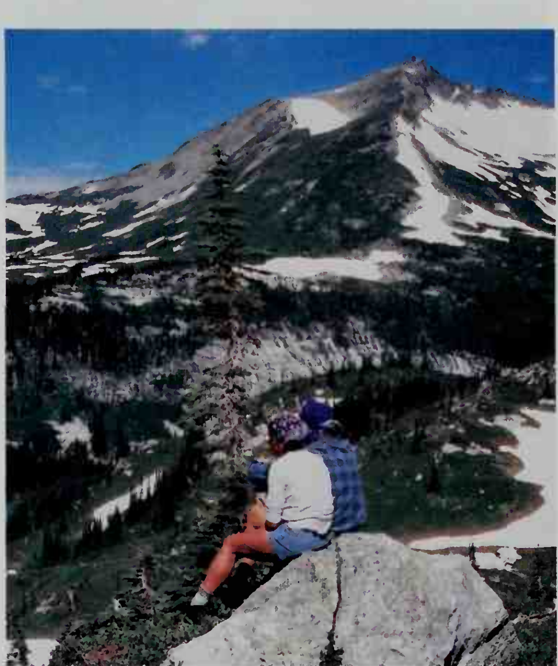
orth Carolina, University of, is a state-supported educational system of higher education. The state-de system consists of a total of 16 institutions, each of iich has its own chancellor. A president heads the en-te university.

Six institutions are called the University of North Car-na. They are in Asheville, Chapel Hill, Charlotte, eensboro, Pembroke, and Wilmington.

The other 10 institutions are Appalachian State Uni-rsity (in Boone), East Carolina University (in Green-e), Elizabeth City State University, Fayetteville State iversity, North Carolina Agricultural and Technical ite University (in Greensboro), North Carolina Central iversity (in Durham), the North Carolina School of the ts (in Winston-Salem), North Carolina State University Raleigh, Western Carolina University (in Cullowhee), d Winston-Salem State University.

The multicampus university offers a wide variety of dies. The North Carolina School of the Arts special-s in the performing arts. The Chapel Hill campus of-s programs in the arts and sciences, business admin-ation, dentistry, education, journalism, law, library ence, medicine, nursing, pharmacy, public health, d social work. North Carolina State University in eigh, which is the largest of the 16 institutions, focus-on agriculture, engineering, design, forestry, textiles, erinary medicine, and physical and mathematical sci-ces.

Each institution in the system grants bachelor's de-es. Most also award master's degrees. East Carolina iversity at Greenville, North Carolina State University Raleigh, and the University of North Carolina at apel Hill and at Greensboro have programs leading doctor's degrees.



he University of North Carolina was chartered in 19. In 1795, it became the first public institution of her education in the United States to begin enrolling students. The university's first campus was at Chapel Hill.

From 1931 to 1972, the North Carolina General Assembly gradually brought all the state-supported four-year colleges and universities into the University of North Carolina to form the 16-campus system.

Critically reviewed by the University of North Carolina

North Cascades National Park is in northwestern Washington. The park's magnificent scenery includes mountain ridges, forested valleys, alpine lakes and meadows, waterfalls, and glaciers. Among the animals that live in the park are bears, cougars, deer, moose, mountain goats, and wolverines. The park also has magnificent cedar and fir forests. The park was established in 1968, along with the adjacent Lake Chelan National Recreation Area and Ross Lake National Recreation Area. For the area of North Cascades National Park, see **National Park System** (table: National parks). For location, see **Washington** (political map).

Critically reviewed by the National Park Service

Robert McKenzie, Tom Stack & Assoc.

North Cascades National Park provides visitors with many scenic attractions, including snow-capped mountains, forested valleys, alpine lakes, and numerous forms of wildlife.

North Central States are the 12 states in the north-central part of the United States. They include Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin.

The western North Central States, which are sometimes called the Great Plains States, contain some of the richest farming land in the world. Corn and wheat fields cover the plains. The states on the eastern edge of the region are sometimes called the Lake States. These states are known for their great industrial centers, in addition to their farms.

Earl Roberge, Photo Researcl

Steep buttes rise beyond a farm near Medora, in southwestern North Dakota. Farms and ranches cover much of the state. North Dakota's economy depends heavily on agriculture.

North Dakota *The Flickertail State*

North Dakota is a Midwestern state of the United States. It lies in the center of the North American continent. The geographic center of North America is near the town of Rugby. North Dakota is mainly a farm state. Its economy is based more heavily on farming than that of any other state except South Dakota. Many North Dakota factories process farm products or farm equipment. Many of the state's merchants also rely on agriculture. North Dakota has a larger percentage of agricultural workers than most other states. About 56 of every 100 North Dakotans live outside of metropolitan areas.

Farms and ranches cover nearly all North Dakota. They stretch from the flat Red River Valley in the east, across rolling plains, to the rugged Badlands in the west. The chief crop, wheat, is grown in every county. North Dakota harvests about three-fourths of the nation's flaxseed. It is also the top producer of sunflower seeds and barley in the country and a leader in the production of oats, pinto beans, rye, and sugar beets.

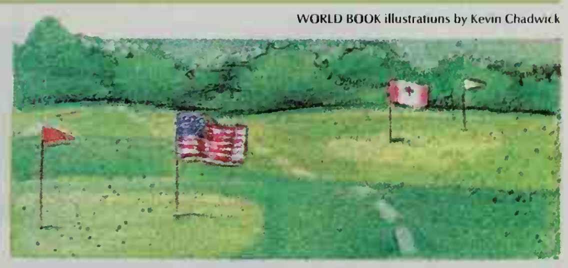
Soil is North Dakota's most precious resource. It is the base of the state's great agricultural wealth. But North Dakota also has enormous mineral resources. These mineral resources include 400 billion to 600 billion tor (360 billion to 540 billion metric tons) of lignite coal. In addition, North Dakota has large oil reserves. Petroleu was discovered in the state in 1951 and quickly becam North Dakota's most valuable mineral resource.

The contributors of this article are Douglas C. Munski, Professor and Chair, University of North Dakota and North Dakota Geographic Alliance, and D. Jerome Tweton, Chester Faritz Distinguished Professor of History, University of North Dakota.

Few white settlers came to the North Dakota region before the 1870's because railroads had not yet entere the area. During the early 1870's, the Northern Pacific Railroad began to push across the Dakota Territory. Large-scale farming also began during the 1870's. Eastern corporations and some families established huge wheat farms covering large areas of land in the Red Ri er Valley. The farms made such enormous profits that they were called *bonanza* farms. White settlers, attract by the success of the bonanza farms, flocked to North Dakota, rapidly increasing the territory's population. Ir 1870, North Dakota had 2,405 people. By 1890, the pop lation had grown to 190,983.

North Dakota was named for the Sioux Indians who once lived in the territory. The Sioux called themselve *Dakota* or *Lakota,* meaning *allies* or *friends.* One of North Dakota's nicknames is the *Peace Garden State.* This nickname honors the International Peace Garden which lies on the state's border with Manitoba. But North Dakota is most often called the *Flickertail State,* because of the many flickertail ground squirrels that l in central North Dakota. Bismarck is the capital of Nor Dakota, and Fargo is the largest city.

Interesting facts about North Dakota



About two-thirds of the lignite coal in the United States can be found throughout the western portion of North Dakota. The size of the resources is estimated at between 400 and 600 billion short tons (360 and 540 billion metric tons). This is considered one of the largest single concentrations of solid fuel in the world.

Lignite coal

North and South Dakota were admitted to the Union simultaneously. On Nov. 2, 1889, President Benjamin Harrison signed the proclamation that made North and South Dakota states. He shuffled the states' admission papers so that one state could not claim to have been admitted before the other. Today, the two are listed alphabetically, making North Dakota the 39th and South Dakota the 40th.

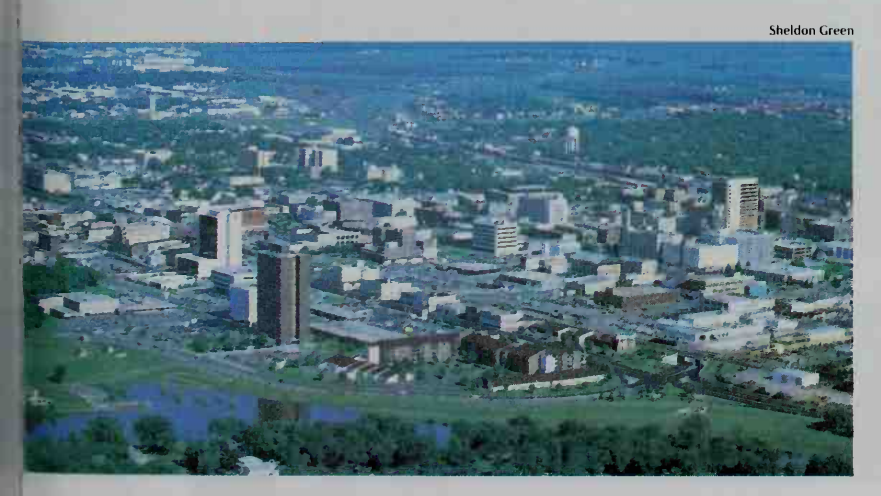
WORLD BOOK illustrations by Kevin Chadwick

International golf course

An international golf course is based in Portal. Part of the course lies in the United States and part is in Canada. An international hole-in-one can be scored on the ninth hole. The tee for the ninth hole is in Canada, and the cup is in the United States. George Wegener scored the first international hole-in-one there in 1934.

The geographic center of North America is located near the town of Rugby in Pierce County.

Sheldon Green



Petroleum is the most profitable mineral in North Dakota. Most of the petroleum is recovered from the thousands of wells located in the western part of the state.

Sheldon Green

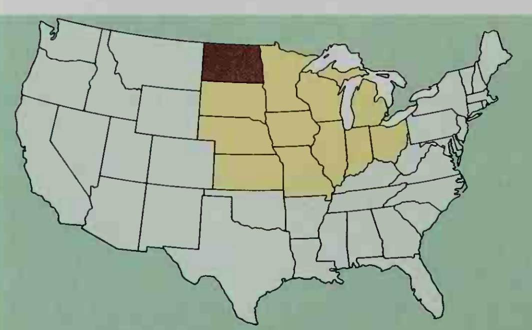
Ranchers round up cattle on a North Dakota farm. Beef cattle rank as the state's most valuable livestock animals. Farmers in North Dakota also raise hogs, sheep, and dairy cattle.

Sheldon Green

Fargo is the largest city in North Dakota. It is one of only four cities in the state with a population of more than 25,000. The other three cities are Bismarck, Grand Forks, and Minot.

North Dakota in brief

Symbols of North Dakota

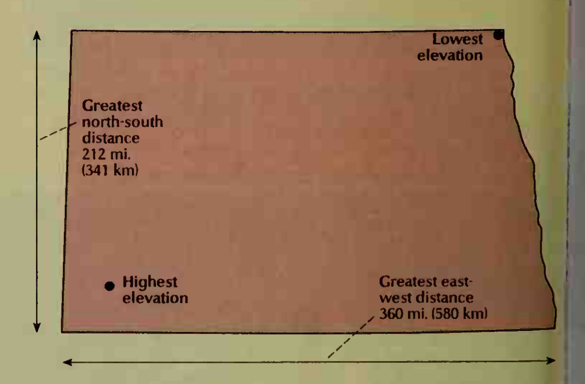


The state flag, adopted in 1911, bears a modified version of the coat of arms of the United States. On the state seal, adopted in 1889, a tree in an open field is surrounded by bundles of wheat, which represent agriculture. A plow, anvil, and sledge also symbolize farming. The bow and arrows and the Indian on horseback chasing a buffalo represent the Indian nations that thrived in the North Dakota region for hundreds of years.

State flag

State seal

North Dakota (brown) ranks 17th in size among all the states and 5th in size among the Midwestern States (yellow).



The State Capitol is in Bismarck, the capital since North Dakota became a state in 1889.

General information

Statehood: Nov. 2, 1889, the 39th state.
Abbreviations: N. Dak. or N.D. (traditional); ND (postal).
State motto: *Liberty and Union, Now and Forever, One and Inseparable.*
State song: "North Dakota Hymn." Words by James W. Foley; music by C. S. Putnam.

Land and climate

Area: 70,704 sq. mi. (183,123 km²), including 1,710 sq. mi. (4,428 km²) of inland water.
Elevation: *Highest*—White Butte, 3,506 ft. (1,069 m) above sea level. *Lowest*—750 ft. (229 m) above sea level in Pembina County.
Record high temperature: 121 °F (49 °C) at Steele on July 6, 1936.
Record low temperature: −60 °F (−51 °C) at Parshall on Feb. 15, 1936.
Average July temperature: 70 °F (21 °C).
Average January temperature: 7 °F (−14 °C).
Average yearly precipitation: 17 in. (43 cm).

Important dates

1738 Pierre Gaultier de Varennes, Sieur de La Vérendrye, made the first explorations in North Dakota.

1803 The United States acquired southwestern North Dakota through the Louisiana Purchase.

1818 The United States acquired northeastern North Dakota in a treaty with Britain.

1863 The Dakota Territory was opened for homesteading.

For information about tourism, write to: Tourism Department, Liberty Memorial Building, 604 East Boulevard, Bismarck, ND 58505-0825. The Web site at www.ndtourism.com also provides information.

For information on the economy, write to: Department of Economic Development and Finance, 1833 E. Bismarck Expressway, Bismarck, ND 58504-6708.

The state's official Web site at discovernd.com also provides a gateway to much information on North Dakota's economy, government, and history.

1889 North Dakota became the 39th state on November 2.

1951 Oil was discovered near Tioga.

1956 The first generator at Garrison Dam began to produce electric power.

1968 Construction began on the Garrison Diversion Project to increase the state's water supply.

1997 Flooding along the Red River caused severe damage, especially in Grand Forks.

People

Population. The 2000 United States census reported that North Dakota had 642,200 people. The population had increased by less than 1 percent over the 1990 figure, 638,800. According to the 2000 census, North Dakota ranks 47th in population among the 50 states.

About 44 percent of the people of North Dakota live within one of the state's three metropolitan areas (see **Metropolitan area**). The Bismarck area is entirely in North Dakota, and the Fargo-Moorhead and Grand Forks areas extend into Minnesota. For the populations of these metropolitan areas, see the *Index* to the political map of North Dakota.

North Dakota has no large manufacturing industries to encourage the growth of big cities. Only 17 cities in the state have more than 2,500 people. Only four have more than 25,000 people. They are, in order of size, Fargo; Bismarck, the state capital; Grand Forks; and Minot. About a third of the state's people live in these four cities.

North Dakota's larger cities still serve their original function as centers of shipping, supply, and trade for the surrounding agricultural region. Most of the factories in North Dakota's cities are small. They manufacture, pack, and process food and food products.

White settlers began to pour into North Dakota by the thousands in the 1870's and 1880's. They were attracted by reports of the large profits made in wheat farming and the availability of free government land. Settlers came from states to the east and south and from Europe. The largest number from other nations came from Norway. They settled throughout the region. Germans from Russia settled in the south-central area, and Canadians moved into the northern Red River Valley. Today, the state's largest population groups are made up of people of German and Norwegian descent.

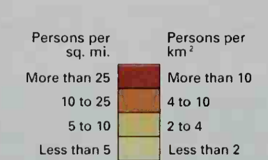
Schools. In 1818, Roman Catholic missionaries set up the first school in the North Dakota region, at Pembina in the northeast. They taught *métis* (people of mixed white and Indian ancestry) of the region and the children of Scottish and Irish settlers who came from Cana da. The school closed in 1823, when Pembina was abar doned. In 1848, Father George Belcourt, a Catholic priest, reopened the school as an Indian mission.

In the early days, teachers traveled from village to vil lage, teaching groups of children in homes. As the settlements grew, the colonists built schools and hired teachers. Railroad companies, anxious to attract settler helped by supplying building materials.

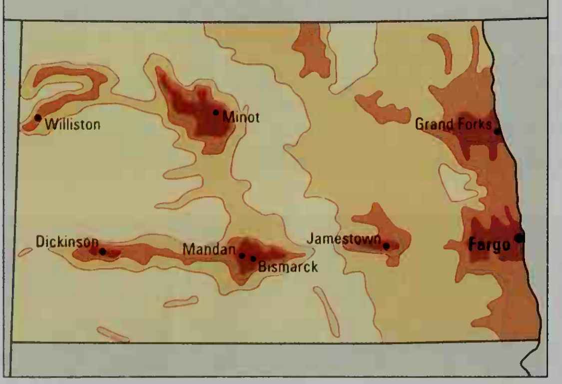
In 1862, the first legislature of the Dakota Territory passed "An Act for the Regulation and Support of Com mon (public) Schools." Between 1862 and statehood in 1889, the territory reorganized its educational system several times. The first state legislature created a fund for the support of all schools teaching the English language. Taxes now support the public schools in North Dakota.

The superintendent of public instruction administer the North Dakota public school system. He or she is elected to a four-year term. This official and a special staff make up the state Department of Public Instructio Children must attend school from ages 7 through 15. F the number of students and teachers in North Dakota, see **Education** (table).

Libraries and museums. Women's clubs did much to organize and improve North Dakota's early libraries In 1897, a women's club opened the state's first public brary at Grafton.



Today, North Dakota has numerous public libraries around the state. In 1898, the state Department of Publ Instruction set up traveling libraries to serve the schoo In 1907, the state library commission (now the North Dakota State Library) was established to administer th traveling libraries and provide other services.



North Dakota State University in Fargo and the Univ sity of North Dakota in Grand Forks have the largest libraries in the state. Both house large collections on North Dakota's history.

The State Historical Society in Bismarck operates a l brary with large collections relating to the state's histo The society also has a museum in Bismarck that incluc exhibits dealing with the life of early North Dakota Ind ans, pioneer days, and natural history. The historical s ciety operates museums at Fort Abercrombie, Camp Hancock, Fort Buford, Fort Pembina, Fort Totten, Whit stone Hill Battlefield, Chateau de Mores, and the form Governor's Mansion in Bismarck.

Population density

Only about half the residents of North Dakota live in urban areas. About a third live in the state's four largest cities—Bismarck, Fargo, Grand Forks, and Minot.

WORLD BOOK map, based on U.S. Census Bureau data.

Universities and colleges

This table lists the universities and colleges in North Dakot that grant bachelor's or advanced degrees and are accredit by the North Central Association of Colleges and Schools.

Visitor's guide

North Dakota's crisp autumn days attract thousands of hunters to streams and lakes where migrating waterfowl pause on their way south. Hunters also shoot grouse, Hungarian partridges, pheasants, and other game birds. Vacationers catch catfish, perch, pike, trout, and other fishes. Favorite summer-resort areas include the Badlands region, including Theodore Roosevelt National Park; Devils Lake; and the Killdeer, Pembina, and Turtle Mountains.

During the summer, musicals are offered at Fort Totten, on an Indian reservation south of Devils Lake. Fort Totten has the nation's only preserved "cavalry square." Variety shows are offered in the Burning Hills Amphitheater near Medora, a picturesque old cow town that has been restored. The town is a popular tourist attraction.

Summer visitors to North Dakota also enjoy colorful Indian powwows conducted on various reservations in the state. Many tourists attend the exciting rodeos that are held in numerous communities throughout North Dakota.

Places to visit

Following are brief descriptions of some of North Dakota's many interesting places to visit:

Bonanzaville, USA, in West Fargo, is a preserved pioneer village. It has 40 buildings, including a church, a one-room schoolhouse, a general store, a log cabin, a town hall, a jail, a drugstore, a hotel and bar, a market, and a museum that features American Indian items.

Chateau de Mores, near Medora, was the home of a Frenchman, the Marquis de Mores, who founded Medora in 1883.

International Peace Garden is a park that lies partly in North Dakota and partly in Manitoba. It symbolizes the long friendship between the United States and Canada. See **International Peace Garden**.

Lake Sakakawea, the reservoir for Garrison Dam, is about 60 miles (97 kilometers) north of Bismarck. The site is popular for swimming, boating, fishing, camping, and picnicking.

Lewis and Clark Interpretive Center, at Washburn, offers displays and exhibits on Native Americans who befriended Lewis and Clark.

Writing Rock, near Grenora, is a large glacial boulder covered with Indian picture writing.

National parklands. Theodore Roosevelt National Park lies in the scenic Badlands. It was established in 1947 in memory of President Roosevelt, who operated two ranches in the area in the 1880's. The park is a wildlife sanctuary. The Knife River Indian Villages National Historic Site, near Stanton, includes the remains of five Hidatsa Indian villages that were occupied until 1845. The Fort Union Trading Post National Historic Site, which North Dakota shares with Montana, was a major fur-trading post in the mid-1800's.

State parks. North Dakota has 18 state parks and campgrounds and many historic and military sites. Fort Abraham Lincoln State Park, near Mandan, is an important historic site. In 1876, Lieutenant Colonel George A. Custer set out from Fort Abraham Lincoln on the expedition that ended in the Battle of the Little Bighorn. Fort Totten, a state historic site on the Fort Totten Indian Reservation, includes a U.S. military post that dates from 1867. For information on the state parks of North Dakota write to Tourism Department, Liberty Memorial Building, Bismarck, ND 58505.

Annual events

January-June

North Dakota Winter Show in Valley City (March); Fort Seward Wagon Train in Jamestown (June); Old Time Fiddlers Contest at the International Peace Garden (June); Frontier Army Days at Fort Abraham Lincoln (June); Fort Union Rendezvous near Williston (June); Medora Musical in Medora (June through Labor Day); special theme events at Trollwood Park in Fargo (June through Labor Day).

July-December

Governor's Cup Walleye Fishing Tournament on Lake Sakakawea (July); Jaycee Rodeo Days in Mandan (July); North Dakota State Fair in Minot (July); Champion's Ride Rodeo in Sentinel Butte (August); Rough Rider Days in Dickinson (July); Pioneer Days at Bonanzaville, USA, in West Fargo (August); Folkfest in Bismarck (September); United Tribes Powwow in Bismarck (September); Norsk Hostefest in Minot (October); Threshing Bee in Makoti (October); Dickens Village Festival in Garrison (November-December).

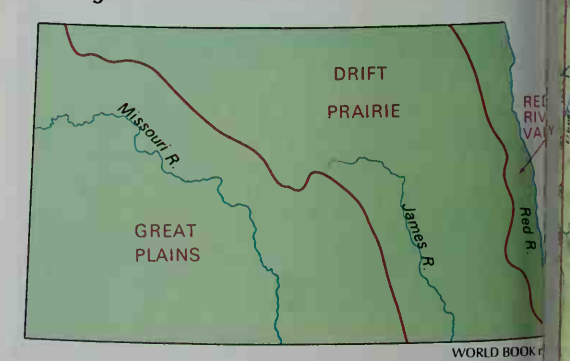
Land and climate

The Red River Valley is one of the most fertile farming areas in the world. It lies along the Red River of the North, which forms the North Dakota-Minnesota border.

Sheldon Green

Land regions. North Dakota has three major land regions: (1) the Red River Valley, (2) the Drift Prairie, and (3) the Great Plains. These regions rise in three broad steps from east to west.

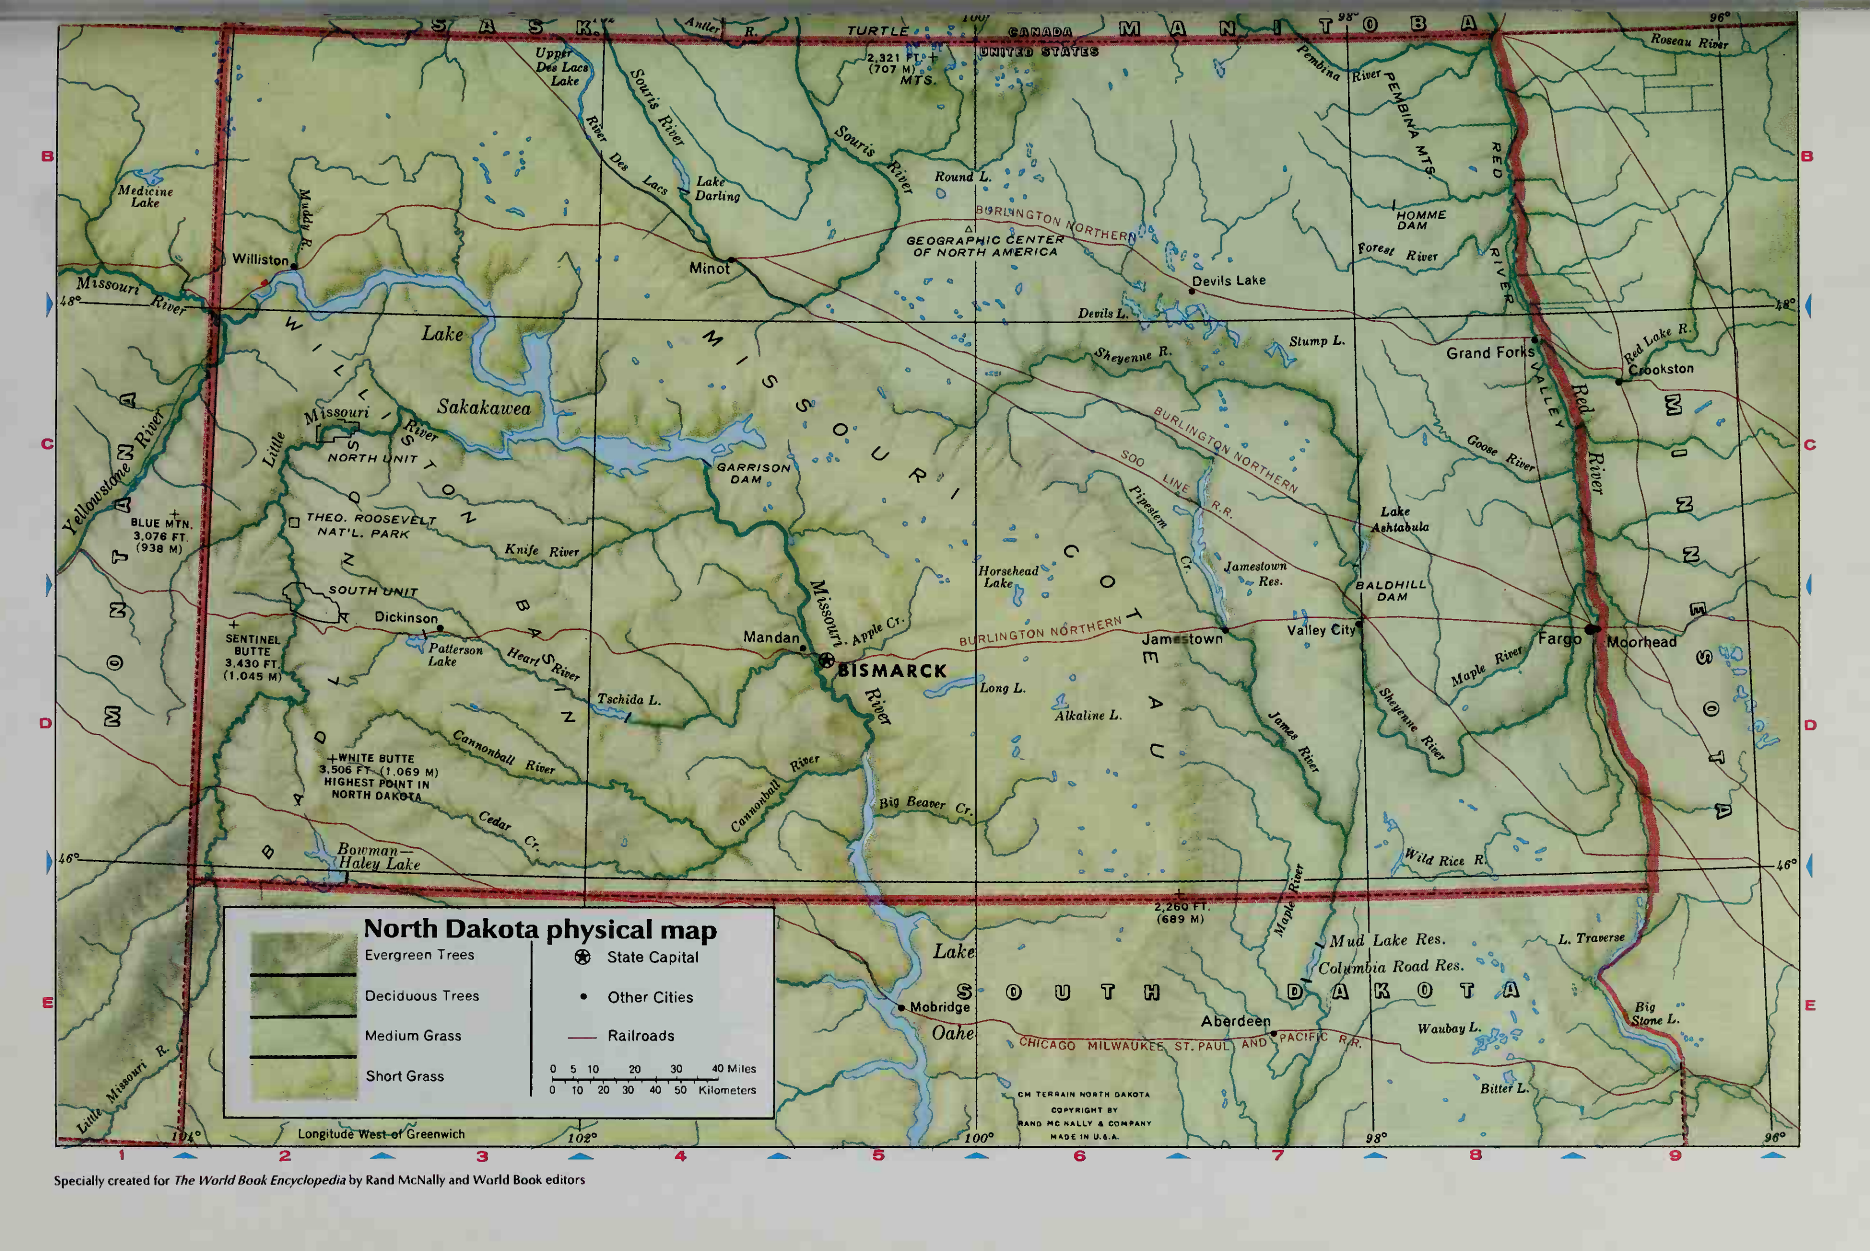
The Red River Valley lies along the Minnesota border. This region is extremely flat. The valley is part of the bed of an ancient glacial lake, Lake Agassiz (see **Lake Agassiz**). The *silt* (soil particles) of the former lake bottom makes this valley one of the most fertile farming areas in the world. Livestock farms and fields of wheat and other crops cover most of the region. The valley is the most heavily populated part of North Dakota.



The Drift Prairie rises on the western border of the Red River Valley. An *escarpment* (steep slope) separates the two regions. The escarpment is steepest in the north in the Pembina Hills (sometimes called the Pembina Mountains), which tower several hundred feet or meters above the Red River Valley. Generally, the Drift Prairie rises gradually toward the west and southwest. Near the region's western border, the land is from 300 to 2,000 feet (91 to 610 meters) above the Red River Valley. The glaciers that crossed the Drift Prairie during the Pleistocene Epoch, which ended about 11,500 years ago, left rich deposits of earth materials called *drift.* The passage of glaciers also earned the area the name *Glaciated Plains.* Most of the region has rolling hills, and is cut by stream valleys. In the north, the Turtle Mountains rise about 550 feet (168 meters) above the surrounding plains. The Drift Prairie has many small lakes where thousands of wild ducks nest every year.

The Great Plains cover the southwestern half of North Dakota. This region is part of the immense highland that extends from northern Canada to southern Texas (see **Great Plains**). North Dakotans call the region the *Missouri Plateau.* The region begins at the Couteau Slope. The slope rises 300 to 400 feet (91 to 120 meters) above the Drift Prairie just east of the Missouri River. It crosses the state from northwest to southeast. The area is hilly, and is used for grazing cattle. It is also rich in mineral deposits.

A narrow band of lowlands called the *Missouri Breaks* follows the sweep of the Missouri River. The area south and west of the river is called the *Slope.* There, rough valleys and *buttes* (steep hills that stand alone) break up the flatness of the plains. Many small streams wind around the hills as they flow toward the larger rivers.



The Badlands of the Little Missouri River lie in the southwest. This strip of rough, beautiful land is 6 to 20 miles (10 to 32 kilometers) wide and about 190 miles (30 kilometers) long. The Badlands are a sandstone, shale, and clay valley in which wind and water have carved weird formations. Buttes, domes, pyramids, and cones colored with bands of browns, reds, grays, and yellows

Specially created for *The World Book Encyclopedia* by Rand McNally and World Book editors

Sheldon Green

The Badlands of North Dakota lie in the southwestern part of the state along the Little Missouri River. Wind and water have carved unusual formations out of sandstone, shale, and clay in this rugged area.

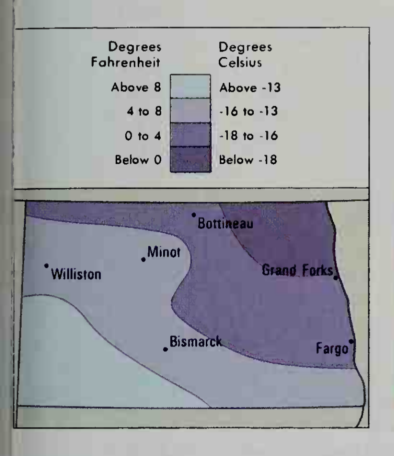
—rise from the floor of the valley. One of the buttes, White Butte, is 3,506 feet (1,069 meters) above sea level, the highest point in North Dakota. In parts of the Badlands, the rocks contain lignite coal. Some coal beds have been burning for many years, turning the clay above them bright red and pink. This burned material, called *scoria,* is used for surfacing roads.

Rivers and lakes. The Missouri River drains about 60 percent of North Dakota, and the Red River of the North drains most of the rest of North Dakota. The great Missouri winds through the western part of the state. Its branches include the Cannonball, Heart, Knife, and Little Missouri rivers. The James River begins in central North Dakota and flows southward into South Dakota. Garrison Dam, 12,000 feet (3,658 meters) long, spans the Missouri near Riverdale. The waters above the dam form Lake Sakakawea. This lake is 178 miles (286 kilometers) long and an average of $3\frac{1}{2}$ miles (5.6 kilometers) wide. The dam helps control floods and provides water for irrigation and hydroelectric power.

The Red River of the North and its branches flow northward through eastern North Dakota and empty into Lake Winnipeg in Canada. The largest branches include the Goose, Park, Pembina, and Sheyenne rivers. The Souris River drains a flat, fertile area in the north-central section. It flows southward from Saskatchewan, and then circles back north into Manitoba.

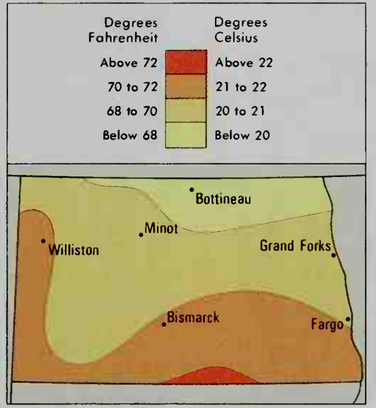
Numerous small lakes dot the Drift Prairie. Many lie in beds scooped out by the glaciers. Devils Lake, in the north-central part of the region, is the largest natural lake in the state. It has no outlet, and its water is salty. The lake has been shrinking, and the state plans to raise the water level.

Plant and animal life. Forests cover only about 1 percent of North Dakota. Trees that grow in the east include the ash, aspen, basswood, boxelder, elm, oak, and poplar. The largest stands of timber are in the Turtle Mountains and Pembina Hills and in the hills surrounding Devils Lake. Ash, cottonwood, elm, and willow trees grow along the Missouri River and its branches.



Sheldon Green

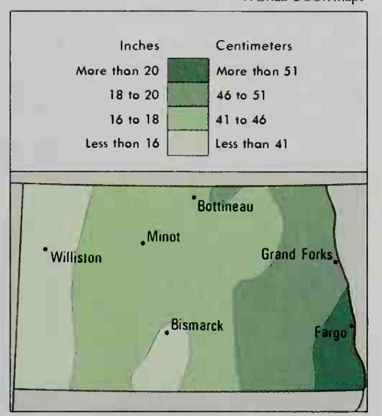
Lake Sakakawea was formed when engineers built Garrison Dam across the Missouri River. The lake is 178 miles (286 kilometers) long.



Average January temperatures

Winters can be bitterly cold. Temperatures are coldest in the northeast and warmest in the southwest.

Average July temperatures



North Dakota has pleasant, sunny summers with low humidity. Temperatures are generally even throughout the state.

Average yearly precipitation

North Dakota is one of the driest of the states. The southeastern corner of the state receives the most precipitation.

WORLD BOOK maps

In spring and summer, brilliantly colored flowers bloom. They include beard-tongues, black-eyed Susans, gaillardias, pasqueflowers, prairie mallows, red lilies, and wild prairie roses. Chokecherries, highbush cranberries, and wild plums grow in many parts of North Dakota. Bluegrass thrives in the northeast, and buffalo and gama grasses thrive in the southwest.

White-tailed deer graze throughout North Dakota. Mule deer and pronghorns range the western plains. In the Badlands, prairie dogs live in scattered colonies called *dog towns.* Fur-bearing animals found in the state include badgers, beavers, bobcats, coyotes, foxes, lynxes, minks, muskrats, rabbits, raccoons, skunks, and weasels. Flickertail ground squirrels are commonly seen.

Every summer, ducks migrate to North Dakota to breed in the lakes, marshes, and grainfields. More waterfowl hatch in North Dakota than in any other state. Game birds include grouse, Hungarian partridges, and pheasants. Fish in the state's waters include bass, carp, catfish, perch, trout, and walleye pike.

Climate. Summers in North Dakota are generally clear and pleasant. The sun shines more than 15 hours on each clear day from mid-May through July. Even the hottest days are seldom uncomfortable because the humidity is low. Winters can be severe. Winds that sweep across the plains make the cold bitter.

July temperatures average 67 °F (19 °C) in the northern part of North Dakota and 73 °F (23 °C) in the south. The state's record high temperature was 121 °F (49 °C), at Steele on July 6, 1936. January temperatures average 3 °F (-16 °C) in the northeast part of the state and 14 °F (-10 °C) in the extreme southwest. The state's lowest temperature, -60 °F (-51 °C), was recorded at Parshall on Feb. 15, 1936.

The southeast has the most precipitation—about 20 inches (51 centimeters) a year. Some western areas of the state receive only about 13 inches (33 centimeters). Most of the rain in North Dakota falls between April and September. Snowfall averages about 32 inches (81 centimeters) yearly.

Economy

The large output of such commodities as grain, beef cattle, and petroleum help make agriculture and mining more important in North Dakota than they are in most other states. However, services and manufacturing continue to grow in economic importance in the state.

Service industries account for the majority of North Dakota's *gross state product*—the total value of goods and services produced annually. The strong agricultural base greatly benefits the service industries. For example, trains carry wheat to wholesale distributors in the state's large cities. Trains are part of the transportation, communication, and utilities industry; and wholesale distributors are part of the wholesale and retail trade industry. Agriculture also benefits North Dakota's manufacturing

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers: Number of people	Employed workers: Percent of total
Wholesale & retail trade	19	98,400	23
Community, business, & personal services	18	125,000	28
Government	15	71,300	16
Finance, insurance, & real estate	13	27,300	6
Transportation, communication, & utilities	10	22,600	5
Agriculture	9	44,000	10
Manufacturing	8	25,700	6
Construction	5	22,900	5
Mining	3	4,600	1
Total	100	441,800	100

*GSP = gross state product, the total value of goods and services produced in a year.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

industry. The state's leading manufactured products include farm machinery and processed foods.

Natural resources. North Dakota's greatest natural resources are its outstandingly fertile soil and its enormous mineral deposits.

Soil is North Dakota's most valuable resource. It is the basis of one of the state's major industries—agriculture. North Dakota's richest soil lies in the Red River Valley. This fertile black soil is free of stones and contains much *organic matter* (decayed plant and animal remains). Loamy and sandy soils lie on the Drift Prairie west of the Red River Valley. Shale and limestone make up most of the soil of the Great Plains region.

Minerals. North Dakota has large deposits of petroleum in the west. These deposits lie in the Williston Basin, which extends from North Dakota into northern South Dakota, eastern Montana, and southern Canada. In North Dakota, this oil field has been developed in about 17 western counties. McKenzie and Williams counties are the leading producers. Bowman County in the southwest and other oil-producing counties in the northwest have natural-gas wells.

North Dakota has large deposits of lignite coal. These deposits lie in the western part of the state. Sand and gravel are found throughout North Dakota. The southwest has great amounts of clay, ranging in quality from common brick to the finest pottery clay.

Service industries provide the largest portion of North Dakota's gross state product. Service industries are concentrated in the state's major urban areas.

Wholesale and retail trade form North Dakota's leading industry in terms of the gross state product. The wholesale trade of food products, mined products, and motor vehicles is important in North Dakota. Major types of retail businesses in the state include grocery stores, hardware stores, restaurants, and service stations. About a third of those employed in retail trade work in restaurants and bars. Several companies run telemarketing operations in rural areas of North Dakota.

Community, business, and personal services are the state's second-ranked service industry. This group employs more people than any other industry in North Dakota. This industry group is made up of a variety of businesses, including private health care, law firms, motels, and repair shops. Fargo, Grand Forks, and Bismarck have large medical centers. These cities also host operation centers for several major corporations.

Government services rank third among the service industries. These services include the operation of public schools, public hospitals, military bases, and Indian reservations. Public schools employ many people, as do U.S. Air Force bases near Grand Forks and Minot. The U.S. government administers several national parks and wildlife refuges in North Dakota.

Finance, insurance, and real estate ranks next among North Dakota's service industries. Real estate is important because of the large amounts of money involved in the purchase of buildings, farmland, and other property. Fargo is North Dakota's center of banking and insurance.

Transportation, communication, and utilities are more important in North Dakota than in most other states because North Dakota's small population is widely scattered. Farm products and mined products often must travel great distances to reach market. Trucks and railroads transport much of the state's farm and coal output. Pipelines transport petroleum and natural gas. Telephone companies are the major part of the communications sector. Utilities provide electric, gas, and water service. More information about transportation and communication can be found later in this section.

Agriculture accounts for a larger portion of the gross state product in North Dakota than in most other states. The state has about 31,000 farms and ranches. Cropland and pastures cover about 85 percent of North Dakota's total land area.

Wheat brings in more income than any other farm product in North Dakota. Only Kansas grows more wheat than North Dakota. Wheat is grown throughout the state, but production in the northern areas is especially heavy. A small percentage of North Dakota's wheat is *durum* wheat—a hard form of wheat used to make spaghetti and other kinds of pasta. North Dakota farmers grow the majority of the nation's durum wheat.

North Dakota leads all other states in the production of barley and sunflower seeds. Farmers grow barley mainly in the eastern part of the state. Sunflowers are grown chiefly in the Drift Prairie region. North Dakota farmers grow the majority of the nation's flaxseed. Flaxseed is the source of linseed oil, which is used to make paint. North Dakota also ranks among the leading producers of canola seed, honey, navy beans, oats, pinto beans, rye, soybeans, and sugar beets.

Hay plays an important role in North Dakota agriculture. The central part of the state produces the most hay. The hay is used almost exclusively as feed for cattle.

Livestock and livestock products account for about a fourth of North Dakota's agricultural income. The raising of beef cattle is the most important type of livestock farming in North Dakota. The central and western plains of North Dakota provide good pasturage and winter feed for beef cattle. Milk ranks second in value among livestock products. Many of the dairy farms are in the south-central part of the state. North Dakota farmers raise hogs in the southeast and south-central areas of the state, where corn is plentiful. North Dakota ranks

A combine harvests wheat on a North Dakota farm. Wheat is the state's leading farm product. North Dakota ranks among the leading states in wheat production.

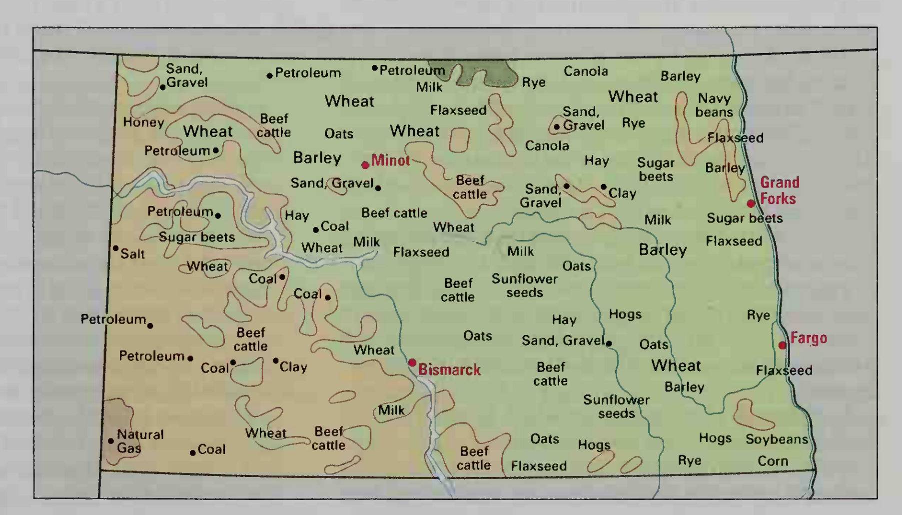
Clayton Wolt, C. J. Photos

'mong the leading states in honey production.

Manufacturing. Goods manufactured in North Dako- ı have a *value added by manufacture* of about $2 $\frac{1}{4}$ bil- on annually. Value added by manufacture represents ıe increase in value of raw materials after they become nished products.

Food processing is North Dakota's leading manufac- ıring activity in terms of value added by manufacture. his industry benefits greatly from the state's strong gricultural base. North Dakota's major food products ıclude bread and pasta, frozen potato products, and ils from oil seeds. The state's dairy products include ıilk and cheddar cheese. Sugar beet refineries operate ı Drayton, Grand Forks, Hillsboro, and Wahpeton. The tate's meat products include steaks and sausages.

The production of machinery ranks second among ıe manufacturing activities of North Dakota in terms of alue added by manufacture. The Bobcat Company, a ɜading manufacturer of construction machinery, is ıeadquartered in West Fargo and has plants in Bis- ıarck and Gwinner. Bismarck, Minot, Wahpeton, and many other cities manufacture farm machinery.



Other products manufactured in North Dakota include fabricated metal products, petroleum products, printed materials, transportation equipment, and wood products. Structural metals and hand tools are important fabricated metal products made in the state. Mandan has a large oil refinery. Newspapers are the leading kind of printed material produced in the state. Aircraft parts are made in Jamestown. Important wood products include cabinets, counter tops, and furniture.

Mining. Petroleum is North Dakota's leading mined product. Oil fields lie in the western part of the state. The most productive field is in McKenzie County. This field is part of the great Williston Basin deposits.

Coal and natural gas are also important mined products in North Dakota. Beds of lignite coal lie under almost all of the western part of the state. McLean, Mercer, and Oliver counties in west-central North Dakota provide most of the coal. All of the state's coal comes from surface mines. The only major natural gas field lies in the southwest corner of the state. Natural gas is ob-

tained as a by-product of oil and coal processing.

Among North Dakota's other mined products, sand and gravel provide the most income. Several areas of the state produce sand and gravel, which are used mainly in road construction. North Dakota's other mined products include clays and salt.

Electric power. Steam plants that burn lignite coal generate over 90 percent of North Dakota's electric power. Most of the rest of the state's electric power is produced by the hydroelectric project at Garrison Dam. Major coal-burning power plants are located at Beulah, Center, Mandan, Stanton, and Underwood. More than half of the electric power generated in North Dakota is exported by high-voltage transmission lines to other Midwestern states, chiefly Minnesota and Nebraska.

Transportation. North Dakota is a large state with a relatively small population. In addition, it is located far from the nation's large population centers. Thus, the state's transportation system is very important. The first railroad in North Dakota, the Northern Pacific, reached Fargo in 1872 and Bismarck in 1873. By 1881, the railroad line ran to the Montana border. Until a bridge was built, trains crossed the Missouri River at Bismarck on a ferry in summer and on tracks over the ice in winter.

By 1881, the Great Northern Railway had established a route between Fargo and Grand Forks. The railway built a line westward through Minot and Williston to the Montana border by 1887. Today, two rail lines provide freight service for North Dakota. In addition, passenger trains serve several North Dakota cities.

North Dakota has about 87,000 miles (139,000 kilometers) of roads and highways. The state's busiest commercial airport is at Fargo.

Communication. North Dakota's first newspaper, the *Frontier Scout,* was published in Fort Union in 1864. In 1873, Colonel Clement A. Lounsberry founded the *Bismarck Tribune,* the oldest newspaper still published in North Dakota. In 1876, Lounsberry wrote the first story of the Battle of the Little Bighorn. In this famous battle, Indians killed Lieutenant Colonel George A. Custer and all the troops under his immediate command. To write the story, Lounsberry used notes found in the buckskin pouch of Mark Kellogg, a reporter who was killed in the battle.

The largest daily newspapers in North Dakota include the *Bismarck Tribune, The Fargo Forum,* the *Grand Forks Herald,* and *The Minot Daily News.* The state's publishers print about 100 newspapers, of which about 10 are dailies. In addition, North Dakota publishers issue about 25 periodicals.

The first radio station in North Dakota, WDAY, started broadcasting in Fargo in 1922. The state's first television station, KCJB (now KXMC-TV), began operating in 1953 in Minot. North Dakota has about 75 radio stations and about 25 television stations. Cable TV systems and Internet providers serve several North Dakota communities.

Government

Constitution. North Dakota is governed under its original Constitution, adopted in 1889. An *amendment* (change) to the Constitution may be proposed in the state legislature. The proposed amendment must be approved by a majority of each house of the legislature. Then a majority of citizens voting on the proposal must approve it. The people may also sign a *petition* (formal request) proposing an amendment. After 4 percent of the people have signed the petition, the proposal is put on a statewide ballot. The proposal becomes law if a majority of voters approve it.

Executive. The governor of North Dakota is elected to a four-year term. The governor may serve an unlimited number of terms.

The lieutenant governor, attorney general, secretary of state, treasurer, auditor, and superintendent of public instruction are also elected to four-year terms. All of these officials may serve an unlimited number of terms. The people of North Dakota also elect three public-service commissioners, and one commissioner each of agriculture, of insurance, and of taxation.

The governor, attorney general, and commissioner of agriculture make up the state Industrial Commission. This commission regulates the North Dakota oil industry. In addition, it oversees the operation of the Bank of North Dakota in Bismarck and of the North Dakota Mill and Elevator in Grand Forks, both of which are state-owned.

Legislature of North Dakota, which is called the Legislative Assembly, has a 49-member Senate and a 98-member House of Representatives. Voters in each of the state's 49 legislative districts elect one senator and two representatives. Senators serve four-year terms, and representatives serve four-year terms.

The Assembly holds its regular session in odd-numbered years, beginning usually on the first Tuesday after the first Monday in January. Regular sessions of the Assembly are limited to 80 legislative, or working, days. The governor may also call special sessions.

Courts of North Dakota are headed by the state Supreme Court. The Supreme Court has five justices, all elected to 10-year terms. The people of North Dakota's seven judicial districts elect a total of 43 district court judges to six-year terms. The Supreme Court and district court judges elect a chief justice of the Supreme Court to a five-year term. All North Dakota judges are elected on a "no party" ballot—the ballot has no political party labels.

Local government. North Dakota has 53 counties. Each county is governed by a board of commissioners of three to five members elected to four-year terms. North Dakota has 361 incorporated cities. The 1967 legislature classed all cities and towns in North Dakota as cities. The cities are organized under mayor-council, city-manager, or commission government.

Revenue. Taxes bring in nearly half of the state government's *general revenue* (income). Most of the remaining revenue comes from federal grants and charges for government services. The largest sources of North Dakota's tax revenue are a general sales tax, a personal income tax, and a severance tax on petroleum extraction. Other important tax revenue sources in the state include taxes on corporate profits, motor fuels, and motor vehicle licenses.

Sheldon Green

The North Dakota House of Representatives meets in the house chambers in the State Capitol, located in Bismarck. Each of the House's members is elected to serve a two-year term.

The governors of North Dakota

	Party	Term

John Hoeven	Republican	2000-

Politics. Throughout most of its history, North Dakota has strongly favored the Republican Party. But the Democrats gained strength in the mid-1900's. The Nonpartisan League, a political organization of farmers, was founded in North Dakota in 1915. During its early years, the league often controlled the Republican Party. In 1956, however, the league joined with the state Democratic Party. This new, strong political force helped to elect Democrats. For example, in 1958, North Dakotans elected the state's first Democrat to the U.S. House of Representatives. This was Quentin N. Burdick. Burdick was elected to the U.S. Senate in 1960. He served as a U.S. senator until his death in 1992.

In 1889, the people elected a Republican as their first governor. For the next 70 years, Republicans held the office of governor most of the time. But since 1961, Democrats have held the office of governor of North Dakota much longer than Republicans have.

North Dakotans have voted for Republican candidates in about four of every five presidential elections. For North Dakota's electoral votes and voting record in presidential elections, see **Electoral College** (table).

History

Indian days. Six groups of Indians lived in North Dakota when white explorers and fur traders first arrived. The Mandan, Hidatsa, and Arikara Indians lived in permanent earthen lodges along the Missouri River. They were farmers but also hunted. The Chippewa resided and hunted in the northeast. The Yankton Sioux lived in the James and Sheyenne river valleys, where they hunted. The largest and most powerful tribe, the Lakota or Teton Sioux, lived in the southwest and were hunters. Led by the great chiefs Sitting Bull and Gall, the Lakota Sioux fiercely resisted the United States Army.

Exploration and early settlement. In 1682, René-Robert Cavelier, Sieur de La Salle, claimed for France all the land drained by the Mississippi River system. This territory included the southwestern half of present-day North Dakota, because the Missouri River—which drains this area—flows into the Mississippi. France also claimed the vast area south of Hudson Bay, which included the northeastern half of North Dakota. In 1713, France gave all this Hudson Bay territory to Britain.

North Dakota was first explored by a French Canadian, Pierre Gaultier de Varennes, Sieur de La Vérendrye. He set out from Canada in 1738 and reached the Mandan Indian villages near present-day Bismarck.

In 1762, France gave its land west of the Mississippi to Spain. Spain returned it to France in 1800. In 1803, the United States bought this region, called Louisiana, from France (see **Louisiana Purchase**).

In 1804, President Jefferson sent Meriwether Lewis and William Clark to explore the Louisiana Territory and to blaze a trail to the Pacific Ocean. They reached central North Dakota in October 1804, and built Fort Mandan on the east bank of the Missouri River, across from present-day Stanton. The explorers stayed at Fort Mandan

The Mandan Indians performed a buffalo dance to ensure success in hunting buffalo. Several Indian tribes lived in the North Dakota region before white explorers arrived.

Water color (1832-1834) by Karl Bodmer; Joslyn Art Museum, Omaha, Nebr.

until April 1805. They passed through North Dakota again in 1806 on their return from the Pacific.

In 1812, Scottish and Irish families from Canada made a permanent settlement in North Dakota, in Pembina. In 1818, the United States obtained northeastern North Dakota by a treaty with Britain. All of present-day North Dakota then became U.S. territory. The 1818 treaty also set the United States-Canadian border at the 49th parallel. Some of the Pembina settlers moved north, to be sure they were on British territory. The rest left in 1823, when a survey confirmed that Pembina was actually located in the United States. A number of *métis* (people of mixed white and Indian descent) remained in the region after the settlers left.

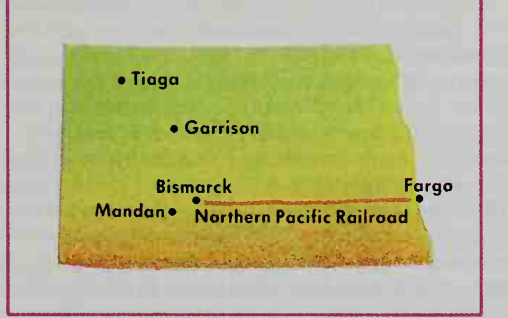
Territorial days. Congress created the Dakota Territory in 1861. President Abraham Lincoln appointed William Jayne as governor. The territory included the present states of North and South Dakota and much of Montana and Wyoming. The first legislature met in Yankton (now in South Dakota) in 1862.

In 1863, the territory was opened for homesteading. Settlers were given free land if they lived on it and improved it. But the territory developed slowly. Transportation was poor, and the settlers feared the Indians. In 1862, Sioux Indians killed hundreds of settlers in an uprising in Minnesota. Some of the Indians then fled to the Dakota Territory. The U.S. government sent troops into the territory to punish the Indians who had taken part in the Minnesota uprising. Several battles were fought as the soldiers pursued the Indians across the territory.

The federal government signed several treaties with the Indians in the Dakota Territory, giving them land on reservations. But the whites often broke the treaties, causing more Indian uprisings. Peace came in 1881, when the great Sioux leader Sitting Bull voluntarily surrendered to U.S. troops. See **Indian wars** (The Sioux wars); **Sitting Bull**.

Large-scale farming began about 1875, when eastern corporations and some families established huge wheat farms. Most of the farms were in the Red River Valley and ranged from 3,000 to 65,000 acres (1,200 to 26,300 hectares). The farms earned such tremendous profits they became known as *bonanza* farms. The farmers used machinery and orderly methods of planting, harvesting, and marketing. This was possible because only one crop —wheat—was raised. In time, other crops were introduced on the bonanza farms. As the bonanza farms developed, cattle companies from the southern plains moved into the Badlands. The future President Theodore Roosevelt was among those who helped open up the land along the Little Missouri River. Most of the bonanza farms were divided into smaller lots and sold to newcomers because low wheat prices in the 1890's made them unprofitable.

Statehood. During the 1870's, the people began to ask Congress to divide the Dakota Territory into two parts. The population centers had developed in far corners of the territory—in the northeast and the southeast. North-south travel between these two centers was difficult because the railroads had laid their tracks in an east-west direction. The two groups of settlers had little in common and wanted their own governments.



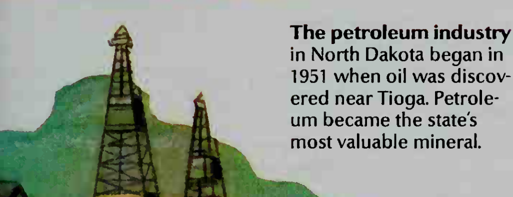
In February 1889, Congress established the present boundary between North Dakota and South Dakota. It also passed an enabling act, allowing the two regions to set up the machinery to become states (see **Enabling Act**). On Nov. 2, 1889, North Dakota became the 39th state, and South Dakota the 40th state. John Miller, a Republican, became North Dakota's first governor.

The early 1900's. North Dakota's population increased rapidly following statehood. The state had 190,983 people in 1890. In 1910, it had 577,056 people. Farming also grew rapidly. However, the farmers disliked having to deal with banks, grain companies, and railroad interests in Minnesota. In addition, they disliked the power that these out-of-state businesses held in North Dakota politics.

In 1915, the Nonpartisan League was founded in North Dakota. This organization supported the farmers. It called for state ownership of grain elevators, flour mills, packing houses, and cold-storage plants. It also wanted banks in farming areas that would grant loans at cost. Thousands of farmers joined the league.

In 1916, a league-supported candidate, Republican

Historic North Dakota



Pierre Gaultier de Varennes, Sieur de La Vérendrye, was the first white person to explore the North Dakota region. In 1738, he reached the Mandan Indian villages near present-day Bismarck while searching for a route to the Pacific Ocean.

The Northern Pacific Railroad built a line to Fargo by 1872 and reached westward as far as Bismarck by 1873. Railroad building brought a rush of settlers to the region, and farming prospered in eastern North Dakota.

Cattle ranching began in North Dakota in the late 1800's. The vast western range lands became a grazing area for cattle driven from Texas. Famous ranches included one owned by Theodore Roosevelt.

The petroleum industry in North Dakota began in 1951 when oil was discovered near Tioga. Petroleum became the state's most valuable mineral.

Garrison Dam, on the Missouri River north of Bismarck, began producing hydroelectric power in 1956. The dam ranks among the nation's largest earth-fill dams.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in North Dakota

1682 René-Robert Cavelier, Sieur de La Salle, claimed for France all the land drained by the Mississippi River. This land included southwestern North Dakota.

1738 Pierre Gaultier de Varennes, Sieur de La Vérendrye, made the first European explorations in North Dakota.

1803 The United States acquired southwestern North Dakota through the Louisiana Purchase.

1804-1806 Meriwether Lewis and William Clark passed through North Dakota on their expedition to and from the Pacific Ocean.

1812 Scottish and Irish settlers made the first attempt at permanent European settlement in North Dakota, at Pembina.

1818 The United States acquired northeastern North Dakota by a treaty with Britain.

1861 Congress created the Dakota Territory.

1863 The Dakota Territory was opened to settlers for homesteading.

c. 1875 The era of bonanza farming began.

1889 North Dakota became the 39th state on November 2.

1915 The Nonpartisan League was founded.

1951 Oil was discovered near Tioga.

1956 The first generator at Garrison Dam began to produce electric power. The dam was completed in 1960.

1968 Construction began on the Garrison Diversion Project to increase the state's water supply.

1986 Congress approved a modified version of the Garrison Diversion Project.

1989 North Dakota celebrated its statehood centennial.

1997 Spring flooding produced enormous damage in the Red River Valley, especially in the city of Grand Forks.

Lynn J. Frazier, was elected governor of North Dakota. During Frazier's administrations, from 1917 to 1921, the state legislature passed a number of progressive laws. Rural schools received more funds. Taxes on farm improvements were lowered. An Industrial Commission was set up to manage businesses begun by the state. In 1919, the Bank of North Dakota was established in Bismarck. In 1922, the North Dakota Mill and Elevator in Grand Forks began operating. These state-owned businesses are still in operation.

The Great Depression struck the entire nation during the 1930's. In addition, North Dakota suffered a severe drought. The state's farm production plunged sharply, and its population also began to decline. The population had reached a peak of 680,845 in 1930.

During the 1930's, the state and federal governments took many steps to help North Dakota farmers. In 1937, the State Water Conservation Commission was created. Since that time, state, federal, and private agencies have set up various projects to provide irrigation and prevent erosion of the soil. These agencies also encourage *dry farming* (farming methods that make the most of limited rain).

The mid-1900's. North Dakota's economy recovered during World War II (1939-1945). Farmers broke all their production records in supplying much food for the armed forces. But in the late 1940's, farm prices sagged as a result of farm surpluses throughout the country. The increased use of machines on farms left large numbers of farmworkers unemployed. Many found jobs in towns and cities, and North Dakota's urban population increased. But thousands could not find jobs in the state and left in search of opportunities elsewhere.

Construction of the great Garrison Dam near Riverdale began in 1946. This dam provides flood control, hydroelectric power, and water for irrigation. The dam was completed in 1960. Two lignite-burning power plants near Stanton have also helped the economy.

Oil was discovered near Tioga in 1951 and became the state's most valuable mineral. By 1970, oil wells were operating in 14 counties of western North Dakota.

In 1957, North Dakota established an Economic Development Commission that works to attract industry to the state. More than 80 North Dakota communities now have their own development commissions. Largely as a result of these commissions, the state's rate of industrial growth ranked among the highest in the country from 1958 to 1969. The U.S. Air Force helped the state's economy during the 1960's. It built bases near Grand Forks and Minot.

The Garrison Diversion Project was started in 1968. It included the construction of a canal system to bring water for irrigation from the Missouri River to large sections of North Dakota farmland. It also included plans to supply water to a number of cities and towns.

Late 1900's. During the early 1970's, growing concerns about the effect the Garrison Diversion Project would have on the environment slowed construction. For example, the Canadian government protested because the project, which called for the transfer of U.S. water into Canada, could have introduced pollutants into Canadian waters. In 1986, the U.S. Congress passed an act that modified the project in response to some of these concerns about the environment. During the 1970's, North Dakota increased coal, oil, and natural gas production as a step toward broadening its economy.

Farm production remained high during the 1980's and 1990's. But state leaders, fearing a possible crop failure or a disastrous drop in farm prices, continued to seek new industry for North Dakota. The number of nonagricultural jobs had been increasing, but not enough to keep up with the decline in farm jobs. The task of attracting new industry to the state remained difficult because North Dakota lies so far from the nation's largest population centers.

In 1997, North Dakota suffered heavy snowfalls that produced damaging spring floods. Flooding of the Red River of the North forced almost 90 percent of the people of Grand Forks to evacuate. Over 70 percent of the buildings in Grand Forks experienced water damage.

Recent developments. In 2000, Congress replaced the Garrison Diversion Project with a new act called the Dakota Water Resources Act. The new law authorized more than $600 million for water supply and recreation projects in the state. Douglas C. Munski and D. Jerome Tweton

North Dakota, University of, is a state-supported liberal arts institution in Grand Forks, North Dakota. It has colleges of aerospace sciences, arts and sciences, business and public administration, education, engineering and mines, fine arts, human resources development, and nursing. It also has a graduate school; schools of law and medicine; and a division of continuing education. A leading coal research facility is also located at the university. The university grants bachelor's, master's, and doctor's degrees. It was founded in 1883.

Critically reviewed by the University of North Dakota

North Dakota State University is a state-controlled coeducational school at Fargo, North Dakota. The university has undergraduate colleges of agriculture; education; engineering and architecture; home economics; humanities and social sciences; pharmacy; science and mathematics; university studies; and a school of education. North Dakota State also has a graduate school. The university grants bachelor's, master's, and doctor's degrees. The university includes the North Dakota Agricultural Experiment Station and the Cooperative Agricultural Extension. The school was founded in 1890 as the North Dakota Agricultural College. It took its present name in 1960. Critically reviewed by North Dakota State University

North Korea. See Korea.

North Platte (pop. 23,878) is the center of a farming and cattle-raising region in western Nebraska. For location, see **Nebraska** (political map). North Platte plays an important role in the U.S. railroad network. Most transcontinental traffic on the Union Pacific Railroad passes through the city's Bailey Yard, a computer-controlled facility for sorting freight cars into trains. Besides railroading, major economic activities in the city include retail trade, tourism, and processing agricultural products.

The famous frontiersman Buffalo Bill built a home near North Platte in 1886. The home is now the site of the Buffalo Bill Ranch State Historical Park. The city also hosts a statewide celebration, Nebraskaland Days, in June each year. The celebration includes a rodeo.

The city was first settled in 1866. It began as a construction camp for workers who were building the Union Pacific Railroad.

North Platte is the seat of Lincoln County. The city has a mayor-council form of government. Laura Johnston

North Pole is a term used for several invisible surface points located in the Arctic region. The best known is the north geographic pole. But other important north poles include the instantaneous north pole, the north pole of balance, the north magnetic pole, and the geomagnetic north pole.

The north geographic pole lies near the center of the Arctic Ocean where all the earth's lines of longitude meet. American explorer Robert E. Peary led the first expedition usually credited with reaching this pole. The expedition included Matthew Henson, who was Peary's assistant, and four Inuit (formerly called Eskimos). They made the trip by dog team in 1909. American explorers Richard E. Byrd and Floyd Bennett are credited with reaching the pole by airplane in 1926, though recent evidence indicates they might not have succeeded. In 1958, the U.S.S. *Nautilus* became the first submarine to pass under the Arctic ice to the pole. In 1978, Naomi Uemura of Japan became the first person to reach the pole alone. He traveled by dog sled.

The instantaneous north pole lies at the point where the earth's *axis* (an imaginary line through the earth) meets the surface. The earth wobbles slowly as it turns around its axis, causing the instantaneous north pole to move. This pole takes about 14 months to move clockwise around an irregular path that is called the *Chandler Circle.* The diameter of this path varies from less than 1 foot (30 centimeters) to about 70 feet (21 meters).

The north pole of balance lies at the center of the Chandler Circle. Its position locates the north geographic pole. Each year since 1900, the north pole of balance has moved about 6 inches (15 centimeters) toward North America. This motion has caused tiny changes in the latitude and longitude of points around the earth.

The north magnetic pole is the farthest point on the earth in the direction of magnetic north. This pole can move many miles or kilometers in a few years. Today, the north magnetic pole is located near Ellef Ringnes Island in northern Canada.

The geomagnetic north pole lies near Etah, Greenland, north of the town of Thule. In the upper atmosphere, the earth's magnetic field points down toward this point. William C. Mahaney

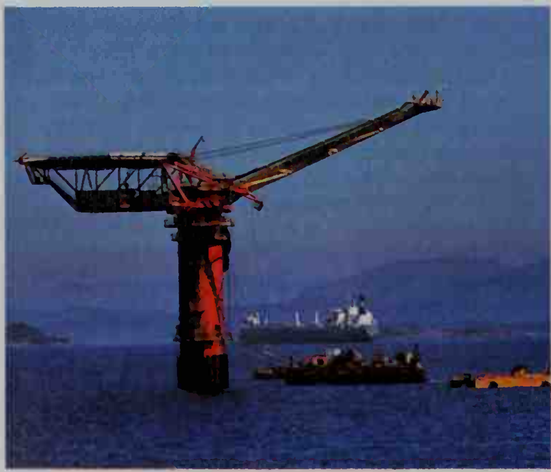
North Sea is a wide arm of the Atlantic Ocean that lies between the island of Great Britain and the mainland of Europe. Seven nations—the United Kingdom, Norway, Denmark, Germany, the Netherlands, Belgium, and France—border the sea. The North Sea is a major trade

and transportation route. It is also an important source of petroleum, natural gas, and fish.

The North Sea covers 218,178 square miles (565,078 square kilometers). It extends almost 600 miles (960 kilometers) from north to south and about 360 miles (580 kilometers) from west to east. It has an average depth of 100 feet (30 meters) in the south and 400 feet (120 meters) in the north. The Strait of Dover and the English Channel connect the North Sea with the Atlantic Ocean. Skagerrak, an arm of the sea, links it with the Strait of Kattegat and the Baltic Sea. The Kiel Canal also connects the North and the Baltic seas.



Weather conditions in the North Sea are unpredictable, especially in winter. Winds of up to 100 miles (160 kilometers) an hour and severe storms sometimes occur, making navigation extremely dangerous.

In the 1960's, vast amounts of petroleum and natural gas were found under the North Sea. Today, the United Kingdom and Norway get large quantities of petroleum from the area. Natural gas is piped ashore to the United Kingdom and Germany.

The North Sea's fishing grounds rank among the richest in the world. Fish caught in the area include cod, haddock, herring, mackerel, pilchard, plaice, sole, and whiting. The sea also provides many kinds of shellfish.

The North Sea is one of the world's most important waterways for commercial activity. Its many major ports include London, England; Hamburg, Germany; Amsterdam and Rotterdam, the Netherlands; Antwerp, Belgium; and Dunkerque, France.

The North Sea has been used for trade and transportation since ancient times. Its position made it important during World War I (1914-1918) and World War II (1939-1945). During World War I, the United Kingdom controlled the North Sea and prevented the German Navy from using it as a route to the Atlantic Ocean. During World War II, Germany controlled the part of the sea between Norway and France. But the United Kingdom controlled the English Channel and the northern approaches to the sea, allowing Allied ships to use the waterway. D. Ian Scargill

© Dotte Larsen, Bruce Coleman Inc.

The North Sea contains vast deposits of natural gas and petroleum. These reserves were discovered during the 1960's and belong mainly to the United Kingdom and Norway. They have become a major energy source for western Europe. This offshore oil rig is pumping petroleum from beneath the sea.

WORLD BOOK map

Location of the North Sea

North-South Ministerial Council is a political body that addresses matters of concern to the entire island of Ireland. It brings together government representatives from the independent Republic of Ireland in the south and from Northern Ireland, which is part of the United Kingdom. The council deals with issues in such areas as agriculture, education, the environment, and health. Its decisions are subject to the approval of the Irish Parliament and the Northern Ireland Assembly, an elected body that has jurisdiction over most local affairs.

The North-South Ministerial Council was established by the 1998 Northern Ireland political settlement. This agreement aimed at ending the violence between Irish nationalists and unionists over control of Northern Ireland. Through the years, the nationalists have wanted Northern Ireland to become part of the Republic of Ireland, but the unionists have favored keeping Northern Ireland part of the United Kingdom. The council meets some goals of both groups. For example, it gives the nationalists an all-island institution. But it also provides the unionists with a way to cooperate with the Republic of Ireland without unification. Brendan O'Leary

See also **Northern Ireland** (History).

North Star is a readily visible star that appears to be almost directly above the North Pole. The term *polestar* is sometimes used for North Star. The North Star is presently Polaris, the brightest star in the constellation Ursa Minor. Polaris is within one degree of the place where the northern extension of the earth's axis pierces the sky. Because of its position, Polaris appears stationary, while other stars seem to revolve around the earth's axis as the earth rotates. As a result, Polaris has served as a guide for navigators through the centuries. Polaris is a star of the second *magnitude*. The brighter a star is, the lower is its magnitude (see **Star** [Brightness of stars]).

Polaris will not always be the North Star because the earth's axis will not always point toward Polaris. The earth's rotational axis changes direction in a circular motion called *precession*. Each end of the axis traces out a fictitious circle in the sky. One complete trip around the circle takes about 26,000 years. Thus, the brighter stars on or near the precessional circle above the earth's North Pole each become the North Star for a certain period. For example, in about 12,000 years, the earth's axis will point north to a spot near Vega in the constellation Lyra. In about 22,000 years, Thuban in the constellation Draco will become the North Star. About 26,000 years

rom now, Polaris will return to its present location rela-ive to the earth's axis, and will be the North Star.

Jorth Vietnam. See **Vietnam.**

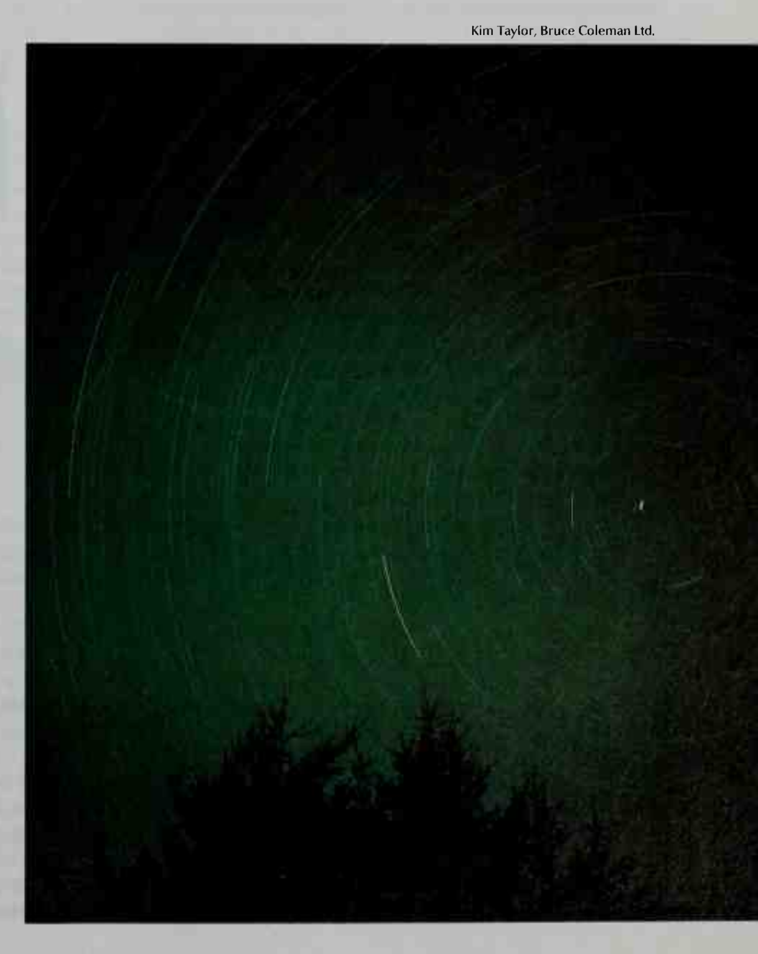
Jorth Warning System is a long-range radar net-vork built to provide the United States and Canada with varning of an air attack from the north. It was complet-ed in 1994. The system extends from northwest Alaska icross northern Canada and down the coast of abrador. It consists of 54 radar stations. NORAD, a U.S.-Canadian military alliance, controls the North Warning System (see **NORAD**).

In 1985, the United States and Canada agreed to im-prove surveillance by replacing the DEW (*D*istant *E*arly *W*arning) line's aging radars and building additional adars. The improved system was renamed the North Warning System. The North Warning System replaced he DEW line after that system was deactivated in 1993.

Critically reviewed by NORAD

Jorth West Company was a Canadian fur-trading company that became the main competition of the pow-erful Hudson's Bay Company during the late 1700's. Ad-venturous North West Company traders explored, napped, and helped open up the little-known regions of northern and western Canada.

The company began to take shape in the 1770's, when several Montreal fur merchants started to combine their operations. The association collapsed during the early 1780's but was reestablished and adopted the name North West Company in 1784. Members of the company became known as Nor'Westers.



At first, the Nor'Westers competed successfully with the Hudson's Bay Company and with John Jacob Astor's Pacific Fur Company. North West Company traders found new sources of pelts while exploring the Far West. Notable Nor'Westers included Alexander Macken-zie and David Thompson. Mackenzie traveled to the Arc-tic Ocean in 1789 and to the Pacific Ocean in 1793. Thompson explored and mapped the Columbia River area between 1807 and 1812. However, competition with the Hudson's Bay Company became increasingly diffi-cult. In 1821, the North West Company faced severe fi-nancial problems and united with the Hudson's Bay Company. Cornelius J. Jaenen

North-West Mounted Police. See **Royal Canadian Mounted Police.**

North West Rebellion was a conflict that arose in 1885 between the *métis* (people of mixed white and Indi-an ancestry) and the Canadian government in what is now Saskatchewan. It resulted from métis fears that gov-ernment plans to encourage new farming settlements in the northwest would threaten their communities.

Kim Taylor, Bruce Coleman Ltd.

The North Star appears at the center of circular racks made by other stars in a time-exposure photo-graph. The earth's rotation on its axis makes other stars seem to rotate around the North Star, which lies near the axis. The North Star may be located by using he group of stars called the Big Dipper, also shown nere. Two of these stars, Dubhe and Merak, are al-most in line with the North Star.

The métis had opposed the government in the Red River Rebellion in 1869 and 1870, in what is now the Canadian province of Manitoba. That conflict also had involved métis fears about the effects of white settlement on their lands. The métis demanded, and obtained, guarantees that the Canadian government would protect their property, cultural, religious, and language rights. The guarantees, however, proved too weak. As a result, the métis retreated west and established new communities in the valleys of the North and South Saskatchewan rivers. There, the métis laid out their small farms in the traditional French river lot pattern, in long strips bordering the rivers.

By the early 1880's, the métis became concerned about the effects of the nearly completed transcontinental railroad and the government's plans for white settlement in Saskatchewan. The government wanted the land divided into square lots, and it refused to approve métis claims for new lots laid out in riverfront strips.

The métis again called on Louis Riel, the leader of their earlier protest in Manitoba. In March 1885, Riel established a temporary métis government to negotiate with the Canadian government. The Canadian government regarded this as an act of treason. All possibility of negotiation ended when the métis and North-West Mounted Police fought near Duck Lake on March 26, 1885. People on both sides were killed. In addition, scattered fighting broke out between some Cree Indians and settlers.

Canada's government sent a military force to Saskatchewan. These troops, joined by the North-West Mounted Police and local volunteers, moved against the métis at Batoche. The métis, seriously outnumbered and poorly equipped, were defeated at Batoche in May 1885. Gabriel Dumont, their military leader, escaped to the United States. Riel was arrested, tried for treason, and hanged in Regina in November 1885.

After the rebellion, people in the northwest gained representation in the Canadian Parliament. Many French-speaking Canadians sympathized with the métis, and the rebellion led to increased tension between French- and English-speaking Canadians. The rebellion accomplished little for the métis. T. D. Regehr

Northcliffe, Viscount (1865-1922), a famous English journalist and publisher, pioneered in the use of comics, special features, religious news, and tabloid newspapers. He also played an important part in the formation in 1916 of the Coalition Cabinet led by David Lloyd George. Northcliffe owned the Amalgamated Press, a large magazine publishing house, and the London *Evening News,* the *Daily Mail,* the *Daily Mirror,* and *The Times.* He was born in County Dublin, Ireland. His given and family name was Alfred Charles William Harmsworth. Joseph P. McKerns

Northeast Passage. See Arctic Ocean.

Norther is a cold winter wind that sweeps over the southern United States, the Gulf of Mexico, and the east coast of Central America, destroying crops and wrecking ships. The northers occur most frequently between October and April. Northers often cause the temperature to rapidly drop as much as 30 to 50 Fahrenheit degrees (17 to 28 Celsius degrees).

The wind usually blows over regions that border the western part of the Gulf of Mexico. Sometimes the wind reaches as far south as Panama. Occasionally, a norther starts as far north as Canada and extends over the entire Mississippi Valley. Scientists can predict a norther about 24 hours in advance. In Central America, this wind is called *el norte.* Richard A. Dirks

Northern harrier, sometimes called *marsh hawk,* is the only species of harrier that lives in North America. It also lives in Europe, where it is called a *hen harrier,* and in northern and central Asia. A *harrier* is a type of hawk.

Northern harriers have long wings, tails, and legs. They measure 17 to 24 inches (43 to 61 centimeters) long with a wingspread of 40 to 54 inches (101 to 137 centimeters). The females grow slightly larger than the males. Adult male northern harriers are mostly light-gray above and white below. Adult females have brown coloring above with dark streaking underneath. The young birds resemble the females but have less streaking below.

Like owls, northern harriers have a saucer-shaped ruff of feathers around the eyes. This ruff, called a *facial disk,* reflects sound to the harrier's ear openings. The northern harrier usually hunts small birds and mammals. Its facial disk helps it detect prey by sound. The bird then swoops down and kills its victim.

WORLD BOOK illustration by John Rignall, Linden Artists Ltd.

Northern harriers help farmers by eating harmful pests. The adult female, *left,* is brown. The adult male, *right,* is gray.

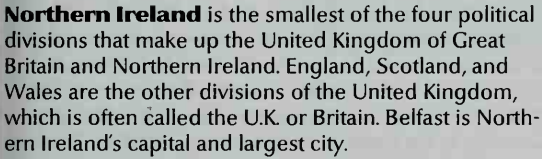
Northern harriers nest on the ground. The males are the only North American birds of prey that typically mate with more than one female during the same period of time. Females usually lay from 4 to 6 eggs.

Richard D. Brown

Scientific classification. The northern harrier belongs to the family Accipitridae. Its scientific name is *Circus cyaneus.*

See also **Harrier; Hawk.**

Northern Hemisphere. See Hemisphere.



Northern Ireland Tourist Board

Belfast is the capital and largest city of Northern Ireland. Donegall Place, in the heart of Belfast, *shown here,* features an outdoor mall lined with shops and offices.

Northern Ireland Tourist Board

The landscape of Northern Ireland has many fertile, rolling plains inland and low mountains near the coast. Shown here are mountains sloping down to a beach on the northern coast.

Northern Ireland is the smallest of the four political divisions that make up the United Kingdom of Great Britain and Northern Ireland. England, Scotland, and Wales are the other divisions of the United Kingdom, which is often called the U.K. or Britain. Belfast is Northern Ireland's capital and largest city.

Northern Ireland occupies the northeastern corner of the island of Ireland. It takes up about a sixth of the island. The independent Republic of Ireland occupies the rest. Northern Ireland is often called *Ulster.* Ulster was the name of a large province of Ireland until 1920, when Northern Ireland was separated from the rest of Ireland.

Religion has long divided Northern Ireland. About half of the people are Protestants, who have traditional ties to the rest of the United Kingdom. Nearly all the rest are Roman Catholics, as are most people in the Republic of Ireland. Most Protestants are *unionists,* who want Northern Ireland to remain in the United Kingdom. Most Catholics are *nationalists,* who want Northern Ireland to become part of the Irish Republic. The dispute sometimes led to riots, bombings, and other outbreaks of violence and terrorism, often called *the troubles.* A political settlement in 1998 promised an end to the troubles. But the agreement proved difficult to implement as the two sides struggled to overcome their mutual mistrust.

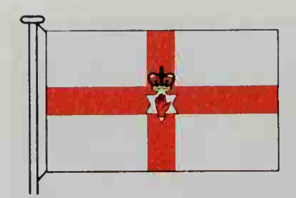
This article tells about the people, geography, economy, and history of Northern Ireland. For a discussion of the United Kingdom as a whole, see **United Kingdom.** For information on the Republic of Ireland, see **Ireland.**

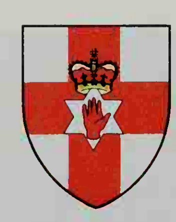
Government

The United Kingdom is a constitutional monarchy. The monarch is the head of state, but a cabinet of officials called *ministers* actually governs. The prime minister, who chairs the cabinet, is the head of government.

Parliament. Laws for the United Kingdom are made by the British Parliament, which consists of the House of Commons and the House of Lords. Northern Ireland elects 18 of the 659 members of the House of Commons. The House of Lords consists mainly of honorary appointees. For more information on the British government, see **United Kingdom** (Government).

The Northern Ireland Office handles a variety of matters including human rights and law and order. The British prime minister appoints a secretary of state for Northern Ireland to head the office.





The 1998 political settlement created three new political bodies: the Northern Ireland Assembly, the North-South Ministerial Council, and the British-Irish Council. These groups began meeting in 1999.

The Northern Ireland Assembly assumes many of the responsibilities formerly handled by the Northern Ireland Office. It enacts local laws in such areas as agriculture, finance, and health and social services. Voters in Northern Ireland elect the Assembly's 108 members. Complex rules attempt to create a balance of power between unionists and nationalists.

The North-South Ministerial Council handles affairs of the entire island of Ireland. It includes representatives

Facts in brief

Capital: Belfast.
Official language: English.
Area: 5,467 mi^2 (14,160 km^2). *Greatest distances*—east-west, 111 mi (179 km); north-south, 85 mi (137 km). *Coastline*—330 mi (531 km).
Elevation: *Highest*—Slieve Donard, 2,796 ft (852 m) above sea level. *Lowest*—The Marsh, near Downpatrick, 1.3 ft (0.4 m) below sea level.
Population: *Estimated 2002 population*—1,647,600; density, 301 per mi^2 (116 per km^2); distribution, 70 percent urban, 30 percent rural. *1991 census*—1,578,000.
Chief products: *Agriculture*—cattle, chickens, eggs, hogs, sheep. *Manufacturing*—aircraft, Irish linen and other textiles, machinery, pottery and china, ships.

Northern Ireland's flag and coat of arms have a six-pointed star and the ancient Ulster symbol of a red hand. The star and hand appear over the St. George's cross of the English flag. Northern Ireland's flag and arms ceased to be official symbols after the United Kingdom took direct control of the country's government in 1972. The flag is often flown by private citizens, but the official flag has always been the British Union Flag.

from the governments of both Northern Ireland and the Republic of Ireland. The council's decisions are subject to the approval of the Irish Parliament and the Northern Ireland Assembly.

The British-Irish Council, also called the Council of the Isles, addresses issues concerning all of Ireland and the United Kingdom. The council brings together representatives from the parliaments of Ireland and the United Kingdom; the assemblies of Northern Ireland, Scotland, and Wales; and the governments of the Channel Islands and the Isle of Man, two British dependencies.

Local government. Northern Ireland is divided into 26 districts, each governed by an elected council. Council members serve four-year terms. The councils handle such services as parks and environmental protection.

People

Ancestry. About half of the people are descended from English and Scottish settlers who arrived in Ireland since the 1600's. Most of the rest trace their ancestry to the earlier Celtic, Viking, and Norman settlers of the island of Ireland.

Language. English is the official language of Northern Ireland, and all the people there speak it. The Irish language, a form of Gaelic once used throughout Ireland, is taught to children in Roman Catholic schools and in some Protestant schools.

Way of life

About two-thirds of the people of Northern Ireland live in urban areas. Many live in or near the cities of Belfast and Londonderry, which is also called Derry. About a third of the people live in rural areas, and most of them earn their living by farming.

Food and drink. The people of Northern Ireland enjoy meals of meat, potatoes, vegetables, and bread. They also eat large amounts of poultry, eggs, dairy products, and fish. Tea is the most popular drink. A favorite alcoholic beverage is beer.

Recreation. Many people in Northern Ireland relax in the evening by watching television. Motion pictures are also popular. As in the rest of the United Kingdom, *pubs* (public houses) are an important part of the social lives of many people in Northern Ireland. People gather in pubs to drink beer and other beverages, eat sandwiches, talk with friends, and listen to music.

The most popular organized sport is football, the game Americans call soccer. Other popular sports include *cricket,* which is played with bats and a ball; *Gaelic football,* which resembles soccer; handball; *hurling* and *camogie,* which are somewhat similar to field hockey; and *rugby,* a game played with an oval ball. Many people also enjoy boating, fishing, golf, and swimming.

Education. All children in Northern Ireland from age 4 through 16 are required to attend school. Nearly all of them go to schools supported by public funds. Children attend a primary school from age 4 to 11. Some then attend a secondary school, which provides general and vocational education, or a grammar school, which prepares students for higher education. Others attend a comprehensive school, which provides both secondary and grammar school courses.

Catholics operate their own schools, so education in Northern Ireland is largely segregated along religious lines. However, some integrated schools have been established by Catholic and Protestant parents who are concerned about the continued segregation.

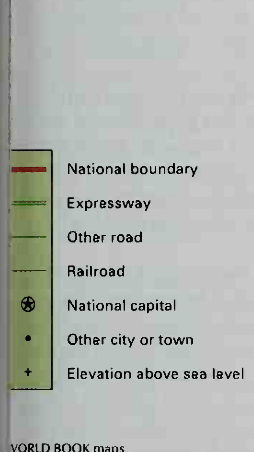
Northern Ireland has two universities. Queen's University is in Belfast. The University of Ulster has branches in Belfast, Coleraine, Jordanstown, and Londonderry.

Religion. About half of the people are Protestants. Most of the rest are Roman Catholics. The Church of Ireland and the Presbyterian Church are the largest Protestant churches. The Church of Ireland belongs to the Anglican Communion, which also includes the Church of England and the Episcopal Church in the United States.

An organization of Protestant men called the Orange Order, also known as the *Orangemen,* holds parades every July 12. The parades celebrate the victory of King William III, a Protestant, over King James II, a Roman Catholic, in the Battle of the Boyne in 1690. The "Twelfth" is a public holiday in Northern Ireland. A similar association of Roman Catholics, the Ancient Order of Hibernians, holds parades on August 15 and sometimes on March 17. August 15 is the Roman Catholic Feast of the Assumption of the Virgin Mary. March 17 is St. Patrick's Day. Saint Patrick is the patron saint of Ireland.

The arts. The most famous cultural event in Northern Ireland is the international arts festival hosted each November by the Queen's University of Belfast. This festival features musical performances, dramatic productions, art exhibits, motion pictures, lectures, and other events.

The Ulster Orchestra and Opera Northern Ireland, both of which perform in Belfast, are well known. In addition, several musicians from Northern Ireland have established international reputations, including the flutist James Galway and the pianist Barry Douglas.



Northern Ireland is also known for talented writers. Poet Seamus Heaney won the 1995 Nobel Prize for literature. Other widely known writers include poet John Hewitt, novelist Brian Moore, and playwright Brian Friel.

The land

Northern Ireland lies on the northeast corner of the island of Ireland. On the south and west, it is bordered by the Republic of Ireland, which occupies the rest of the island. The North Channel separates Northern Ireland from Scotland to the northeast. The Irish Sea separates Northern Ireland from England to the southeast. For more information about the geography and climate of Northern Ireland, see *The land* and *Climate* sections in the **United Kingdom** article.

Northern Ireland

0 25 50 75 100 Miles
0 25 50 75 100 125 150 Kilometers

VORLD BOOK maps

Surface features. Northern Ireland is a land of olling plains and low mountains. The plains, which cover the central part of the region, include fertile fields ınd pasturelands. The mountains, which are near the oast, have many deep, scenic valleys. In some areas, he plains reach to the coast.

The highest peak in Northern Ireland is Slieve Donard pronounced *sleev DAHN uhrd).* It rises 2,796 feet (852 neters) in the Mourne Mountains near the southeast oast. Other mountain ranges include the Sperrin Mountains in the northwest and the Mountains of Antrim in the northeast.

Lakes, rivers, and bays. Northern Ireland has many smooth, clear lakes called *loughs* (pronounced *lahks).* Lough Neagh *(lahk NAY),* near the center of the land, overs about 150 square miles (388 square kilometers). It s the largest lake in the United Kingdom and the largest body of water on the island of Ireland.

The longest river in Northern Ireland is the River Bann. The Bann is actually two rivers. The Upper Bann, which is 47 $\frac{1}{2}$ miles (76.4 kilometers) long, begins in the Mourne Mountains and flows northwest into the southern end of Lough Neagh. The Lower Bann begins at the northern end of the lake and flows north 38 miles (61 kilometers) into the Atlantic Ocean.

Several large bays, which are also called loughs, cut nto the coast. Lough Foyle and Belfast Lough provide excellent harbors for Londonderry and Belfast.

Economy

Service industries rank as leading employers. The major service industries include education, government services, health care, and wholesale trade.

Manufacturing. One of Northern Ireland's most famous manufactured products is Irish linen, which is known for its excellent quality. Most linen mills are near Belfast and Londonderry. Other mills produce woolen and cotton textiles and synthetic fibers.

Beautiful pottery and hand-cut crystal are also made in Northern Ireland. The village of Belleek in the district of Fermanagh is famous for its delicate china.

Shipyards in the Belfast area have built many warships, ocean liners, and tankers. Aircraft plants in the area make commercial and military planes. Other products manufactured in Northern Ireland include automobile parts, chemicals, computer chips, processed foods, and videocassette recorders.

Agriculture and fishing. Cattle, chickens, eggs, hogs, milk, potatoes, and sheep are among Northern Ireland's most important agricultural products. Much barley and hay are grown for animal feed. Other farm products include butter, cheese, mushrooms, and turnips. Orchards in the district of Armagh produce apples, pears, and plums.

The fishing fleet of Northern Ireland brings in large catches of cod, herring, mackerel, shrimp, and whiting, mainly from the Irish Sea. Salmon and trout are netted in the Rivers Foyle and Bann.

Transportation and communication. An excellent road system crisscrosses Northern Ireland. A government-operated railroad system links Belfast and Londonderry with each other, with Portadown and Bangor in

Karin Daher, Gamma/Liaison

A demonstration in Londonderry marks an anniversary of Sunday, Jan. 30, 1972. On that day, 14 Catholics were killed when British soldiers fired at a crowd of protesters. Violent incidents have been part of the long conflict between those who want Northern Ireland to remain in the United Kingdom and those who want it to become part of the Republic of Ireland.

northern Ireland, and with Dublin in Ireland. Large amounts of freight pass through the seaports of Belfast, Coleraine, Larne, Londonderry, and Warrenpoint. Regular passenger ferry service connects Belfast and Larne with cities in western Scotland. Belfast International Airport is the only airport in Northern Ireland that handles international flights.

Northern Ireland has three daily newspapers, all published in Belfast. They are the *Belfast Telegraph,* the *Irish News,* and the *News Letter.* Two British Broadcasting Corporation television channels and two independent channels serve Northern Ireland.

History

This section deals mainly with the history of Northern Ireland from the Protestant settlement in the 1600's to recent developments. For information on the early history of the island of Ireland, see **Ireland** (History).

Protestant settlement. In 1541, King Henry VIII of England became king of Ireland. The Reformation, during which Henry changed England from a Roman Catholic to a Protestant nation, had little effect on Ireland. English rule there was ineffective, and most Irish people remained Catholics.

In 1607, local Irish chieftains who opposed the English fled from Ulster, a large province in northern Ireland. King James I of England then gave the chieftains' land to English and Scottish Protestants. This action was partly responsible for the Protestant majority found in Northern Ireland today.

In the 1600's, two attempts were made to reestablish Catholic power in Ireland. The first was an uprising that began in 1641 and was not put down by English forces until 1653.

The second attempt was made under James II, a Catholic who became king of England in 1685. Many English people were unhappy with James's policies and feared that a Catholic succession to the throne would be established. In 1688, the English invited William of Orange, a Protestant, to invade England with Dutch forces. James fled, and William of Orange was crowned as King William III in 1689. Meanwhile, James went to France and then to Ireland, where he organized an army to fight William. But James was defeated by William in the Battle of the Boyne in 1690. After the battle, Anglican Protestants owned most of the land in Ireland, controlled Ireland's Parliament, and restricted the rights of Catholics and Presbyterian Protestants alike.

Union with Britain. In 1801, the Act of Union took effect. This act abolished the Irish Parliament and created the United Kingdom of Great Britain and Ireland. During the 1800's, the standard of living in northern Ireland rose, as manufacturing flourished. But southern Ireland, where most of the Catholics lived, had a low living standard due to unequal distribution of land and a growing population.

In 1886, the British Liberal Party proposed a plan for Ireland called *home rule.* Under this plan, Ireland would have remained part of the United Kingdom, but it would have had its own parliament for domestic affairs. Ulster Protestants, who feared that such a parliament would be Catholic, opposed the plan. The plan was defeated in the British Parliament.

The division of Ireland. By the early 1900's, most Irish Catholics favored complete independence from Britain. But most of the Protestants in Ulster opposed independence because they did not want to be a minority in a Catholic country. In 1919, 73 Irish members of the British Parliament met in Dublin and declared all Ireland an independent state. Guerrilla warfare then broke out between the Irish rebels and British forces.

In 1920, the British Parliament passed the Government of Ireland Act. This act divided Ireland into two separate political units and gave each some powers of self-government. Ulster Protestants accepted the act, and the state of Northern Ireland was formed from six counties in Ulster. But southern Catholics rejected the act and demanded complete independence for a single, united Irish republic. In 1921, southern leaders and the United Kingdom signed a treaty that created the Irish Free State from 23 southern counties and 3 counties of Ulster. In 1937, the Irish Free State adopted a new constitution and changed its name to Éire (in Gaelic) or Ireland (in English). In 1949, Ireland cut all ties with the United Kingdom and became an independent republic.

Under the 1920 act, Northern Ireland was given its own governor, parliament, prime minister, and cabinet. The governor served as the official head of state, but the prime minister and cabinet held most of the power. Northern Ireland's two-house Parliament handled such matters as administering the educational system and regulating commerce and agriculture. Certain other powers, such as levying income taxes and maintaining armed forces, were reserved for the British Parliament. Throughout Northern Ireland's period of self-rule, the Unionist Party—which favored continued union with the United Kingdom—controlled the government.

Problems of division. Many Roman Catholics in Northern Ireland refused to accept the 1920 division of Ireland, and the new government made little effort to win their loyalty. In some areas where Catholics formed a majority, election districts were set up to ensure that Unionist minorities won control of local councils.

The division of Ireland was also opposed by the Irish ree State and, later, by the Republic of Ireland. Begin-ıing in 1921, armed groups crossed into Northern Ire-ınd and attacked British installations. They hoped to ɔrce the British to give up control of Northern Ireland.

The civil rights movement. Catholics in Northern reland had long claimed that Protestants violated their ivil rights and discriminated against them in jobs, hous-ıg, and other areas. When the government tried to stop civil rights demonstration in Londonderry in 1968, ıloody riots broke out. Serious riots occurred again in 969 in Belfast and Londonderry. Troops were sent to Jorthern Ireland to restore order but failed to prevent ɹrther rioting. Meanwhile, the pro-Catholic Irish Repub-can Army (IRA) and other militant groups carried out ıombings and other terrorist attacks.

The continuing conflict led the British government ɔ suspend Northern Ireland's government in 1972 and ɔ rule the region directly from London. But the troubles ontinued. In 1973 and 1982, the United Kingdom set up ssemblies in Northern Ireland that were designed to estore control over local affairs to the region. However, ıck of cooperation between the Protestants and Cath-ılics led the British government to dissolve both assem-ılies.

In 1985, the United Kingdom and the Republic of Ire-ınd signed the Anglo-Irish Agreement, which gave the overnment of the Irish Republic an advisory role in Jorthern Ireland's affairs. Both Unionists and the IRA trongly opposed the agreement, and protests against ıe British government took place.

In the late 1980's and early 1990's, terrorist bombings y the IRA and related groups intensified. The attacks ɜd to violent responses by Protestant terrorist groups. ı late 1994, the IRA and the Protestant groups declared cease-fire, but bombings resumed in 1996.

Recent developments. Another cease-fire was an-ounced in mid-1997. In September of that year, formal egotiations began that aimed to end the violence over Jorthern Ireland. The talks were the first to include all arties involved in the conflict. In April 1998, the talks nded with an agreement that was then put to referen-ums in both Ireland and Northern Ireland. Voters ap-roved the agreement, which included a commitment to sing peaceful means to resolve political differences. he agreement called for the establishment of a North-rn Ireland legislative assembly with control over many ɔcal matters. It also called for the establishment of a Jorth-South Ministerial Council, which would include overnment representatives from Northern Ireland and reland, and for a British-Irish Council, which would in-lude representatives from the Irish parliament and the arious legislative assemblies of the United Kingdom. In ıid-1999, implementation of the agreement was de-ıyed by disagreements over IRA disarmament.

The new governing bodies began meeting in Decem-er 1999. Early in 2000, the agreement was suspended /hen the Protestants threatened to withdraw from the overnment to protest a lack of disarmament by the IRA. fter months of negotiations, the IRA proposed a new ısarmament plan, and the power-sharing government ɜsumed. The government was threatened again in 2001 y further disagreements over IRA disarmament. These isputes were resolved later in 2001 when international monitors confirmed that the IRA had begun to disarm.

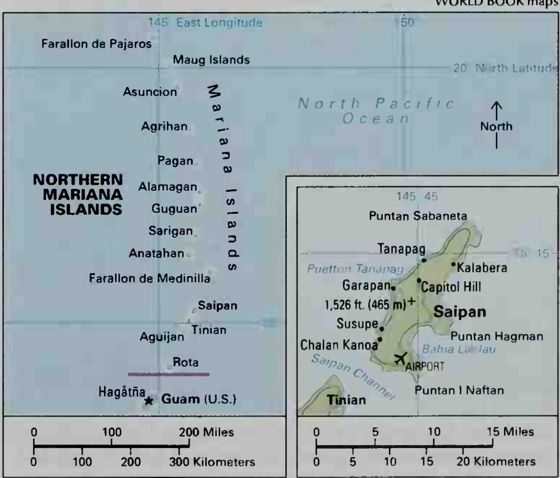
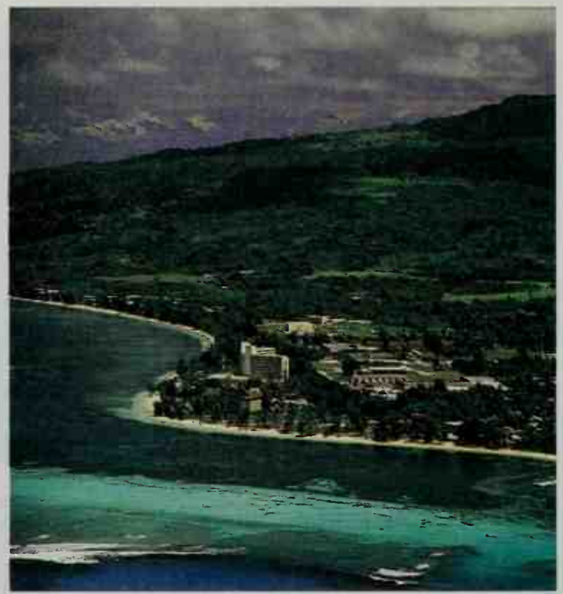
Northern Mariana Islands, Commonwealth of the, is a chain of 16 islands in the Pacific Ocean. The islands are a commonwealth of the United States. They lie about 1,000 miles (1,600 kilometers) south of Japan and about 1,500 miles (2,400 kilometers) east of the Philippines.



The Northern Marianas extend about 337 miles (543 kilometers) from north to south and cover about 184 square miles (477 square kilometers) of land. They are part of a larger region in the Pacific Ocean called *Micronesia.* Together with Guam, the Northern Marianas make up the Mariana Islands.



About 87,000 people live in the Northern Marianas. About 90 percent of the population lives on Saipan, the capital and largest island. Most of the rest of the people

The Commonwealth of the Northern Mariana Islands is in the Pacific Ocean. Chalan Kanoa, *above,* is one of the commonwealth's largest towns. It lies on the island of Saipan.

live on Tinian, the second largest island; and Rota, the third largest. The largest town is Garapan, on Saipan. Government offices are in Susupe and Capitol Hill, which are also on Saipan.

In 1947, the United States began administering the Northern Marianas as part of the Trust Territory of the Pacific Islands. The Northern Marianas became a self-governing commonwealth of the United States in 1986. The commonwealth government handles the commonwealth's internal affairs. The United States is responsible for defense and foreign affairs. Island residents are U.S. citizens, but they cannot vote in presidential elections.

Government. A governor heads the commonwealth government. The governor is assisted by a lieutenant governor. The voters elect both these officials to four-year terms. A two-house legislature makes the commonwealth's laws. The Senate has 9 members and the House of Representatives has 18 members. Members are elected to two-year terms. The voters of Rota, Tinian, and Saipan also elect their own mayor. The remaining islands elect and share one mayor.

People. About one-third of the people of the Northern Marianas are Chamorros. Their ancestors had begun settling on the islands by about 1500 B.C. Another main group is the Carolinians, whose ancestors began to settle on Saipan around 1815 after typhoons destroyed their homes in southern Micronesia. Foreign workers account for over half the population. Filipinos make up the largest group of these workers.

At home, the Chamorros speak Chamorro and the Carolinians speak Carolinian. But English is also widely spoken in the Northern Marianas, particularly among young people. Many older people speak conversational Japanese. The majority of the people are Roman Catholics. However, many islanders also hold beliefs and observe *taboos* (forbidden actions) from local religions.

There are about 14 schools in the Northern Marianas, including a two-year college. The law requires children from 6 through 16 years of age to attend school. English is the main language of instruction.

Many houses on the islands are made of wood or cement block with sheet metal roofs. Modern apartment buildings and condominiums have been built on Saipan.

Land and climate. The Northern Marianas are formed by the peaks of a huge undersea mountain range. The range rises more than 6 miles (9.5 kilometers) off the bottom of the Mariana Trench, the deepest known spot in the world's oceans. The northern islands are covered with volcanic rock. Seven of them—Alamagan, Anatahan, Agrihan, Farallon de Pajaros, Guguan, Sarigan, and Pagan—still have active volcanoes. Limestone terraces cover volcanic rock on the southern islands. The Maug Islands, a cluster of three islands, are sometimes counted as one island. The Northern Marianas have an average year-round temperature of about 84 °F (29 °C) and an average annual rainfall of about 84 inches (213 centimeters).

Economy. The government is the major employer in the Northern Marianas. Tourism ranks as the most important economic activity. The garment industry is the only significant manufacturing activity. Imports in the Northern Marianas far outnumber exports. More than half of the work force in the Northern Marianas are foreigners. The majority of the garment workers are Chinese or Thai. Many islanders hold government jobs.

History. The ancestors of the present-day Chamorros had begun living on the Northern Marianas by about 1500 B.C. In A.D. 1521, Ferdinand Magellan, a Portuguese explorer in the service of Spain, discovered Rota and Guam. Spain claimed the islands in 1565. But Spain did not begin ruling them until 1668, after Spanish Jesuits established a missionary settlement on Guam.

At the end of the Spanish-American War in 1898, Spain turned Guam over to the United States. The next year, Spain sold the Northern Marianas to Germany. Germany ruled the Northern Marianas until the Japanese seized them at the beginning of World War I in 1914. After the war ended in 1918, a mandate from the League of Nations gave Japan control of the islands.

The United States gained control of the Northern Marianas in 1944, during World War II. In 1947, the United States began administering the islands as part of the United Nations Trust Territory of the Pacific Islands. In 1975, the United States agreed to make the Northern Marianas a self-governing U.S. commonwealth. The agreement took effect Nov. 3, 1986. Michael R. Ogden

Northern Territory is a tropical area in north-central Australia. It has large regions of only partly explored land. The Northern Territory covers 519,800 square miles (1,346,200 square kilometers). Its population of 175,253 includes many Aborigines whose ancestors lived in Australia before white people arrived (see **Australia** [The Aborigines]). Tribal conditions still exist among some of the Aborigines. Darwin is the capital and largest city in the Northern Territory. For a detailed map of the area, see **Australia** (political map).

meters) has many bays. The interior is mostly flat. The northern area has excellent grazing regions. The south is sandy. Rivers include the Victoria, Daly, Roper, and South Alligator. Average January temperatures in the Northern Territory range between 80 °F (27 °C) and 95 °F (35 °C), and July temperatures average 77 °F (25 °C). The annual rainfall varies throughout the Northern Territory. Darwin, on the northern coast, has an average of 58 inches (147 centimeters) a year. In the dry interior, rainfall seldom exceeds 11 inches (28 centimeters) a year.

Mining is the chief industry of the Northern Territory. Bauxite, copper, gold, mica, tantalite, tin, and uranium are the chief minerals. Tourism and cattle breeding are the next leading industries. The open spaces and outdoor life of the territory help attract tourists. Large cattle *stations* (ranches) cover extensive areas in the territory. About 1,067,000 cattle, 36,000 horses, and 9,000 sheep graze in the Northern Territory. Pearling is another important industry.

An official appointed by the governor general of Australia on the advice of the federal government administers the government of the Northern Territory. A legislative assembly with 25 members is elected every four years to make laws for the territory. The territory elects two members to the federal House of Representatives. The territory

The Northern Territory covers a huge area in north-central Australia. The interior of the territory is dry and flat except for some low mountains and scattered rock formations.

elects two members to the federal Senate.

The federal government provides medical services for the Northern Territory. A "Flying Doctor" operation uses radio and aircraft service to help the sick and injured at isolated mines and cattle stations.

The explorer John McDouall Stuart first entered the Northern Territory in 1860. His explorations opened up much of the area. An overland telegraph line, completed in the 1870's, followed Stuart's trail from Adelaide to Darwin. The Northern Territory was part of New South Wales until 1863 when it was annexed to the province of South Australia. The Australian federal government took over the administration of the territory in 1911. In 1978, the federal government granted the Northern Territory self-government. K. H. White

Northfield (pop. 17,147) is a city in southeastern Minnesota. It lies about 40 miles (64 kilometers) south of St. Paul. For location, see **Minnesota** (political map). The notorious Jesse James gang tried to rob a bank in Northfield in 1876, but the bank clerk refused to open the vault. James escaped, but several gang members were killed or captured. The bank is now a historical museum. The city is the home of Carleton and St. Olaf colleges. Northfield's industries include food processing and the production of electronic circuits. The city is named for John W. North, who founded it in 1855. Northfield has a mayor-council form of government. Clifford E. Clark, Jr.

Northrop, John Howard (1891-1987), an American biochemist, shared the 1946 Nobel Prize in chemistry with James B. Sumner and W. M. Stanley. Northrop prepared in crystalline form several pure enzymes and one of the viruses that destroy bacteria (see **Enzyme**). Northrop's writings on enzymes include *Crystalline Enzymes* (1939). He was born in Yonkers, New York. He received his doctor's degree from Columbia University in 1915 and was a member of the Rockefeller Institute (now Rockefeller University) in New York City from 1924 until his death. Eric Howard Christianson

Northwest Ordinance was an important law passed by the United States Congress on July 13, 1787. The ordinance provided for the government of the region north of the Ohio River and west of Pennsylvania, then called the Northwest Territory. It became a model for all territories that later entered the Union as states. The ordinance was largely the work of General Nathan Dane and political leaders Rufus King and Manasseh Cutler.

Under the terms of the ordinance, the territories could achieve equality with the older states by passing through three steps leading to full self-government: (1) Congress, which governed the territory, appointed a governor, a secretary, and three judges. (2) When the territory, or any division of it, attained an adult male population of 5,000, it could choose a legislature and send to Congress a delegate who could speak there but not vote. (3) When the total population reached 60,000, the territory could apply for admission into the Union on terms of full equality with the older states. The ordinance removed the danger of colonial rebellion because it assured the territories of participation in the national government.

The Northwest Ordinance provided more than a plan of government. It laid the groundwork for social and political democracy in the West. It forbade slavery. All people were guaranteed trial by jury and freedom of religious worship. The ordinance guaranteed fair treatment for the Indians and declared that "means of education shall forever be encouraged."

The terms of the Northwest Ordinance were so attractive that pioneers poured into the new territory. In 1788, one of the first groups of settlers founded the town of Marietta, Ohio. Thousands of families followed the first settlers in the westward movement. The territory eventually became five states—Ohio, Indiana, Illinois, Michigan, and Wisconsin. The territory included what is now the part of Minnesota east of the Mississippi River.

William E. Foley

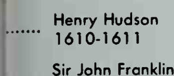
Northwest Passage is a water route, long sought by explorers, across or around North America. The explorers who followed Christopher Columbus soon found that North America was not a part of Asia, as they had believed at first. At that time, English, French, and Dutch adventurers were more interested in finding an easy route to Asia than they were in exploring and settling North America. So they began to look for a "Northwest Passage," or waterway, that would take them around or through the North American continent.

The search for the Northwest Passage is a tale of adventure and heroism. In 1524, Giovanni da Verrazzano, sailing under the French flag, tried to find the passage. He probably explored as far north as Maine.

Jacques Cartier, while exploring for France in 1535, found the St. Lawrence River. He was seeking a route to China. Henry Hudson was sent out many years later by the Dutch East India Company to find a shorter route to the South Seas. He thought he had found that route in 1609 when he sailed into New York Bay and some distance up the Hudson River. In 1610, Hudson explored the Hudson Strait and Hudson Bay while searching for the Northwest Passage.



No country tried harder than England to find the passage. Sir Martin Frobisher began a series of English expeditions in 1576. Other English navigators continued these explorations for 300 years. Frobisher made many important findings, including Frobisher Bay, an indentation in Baffin Island. John Davis followed Frobisher and sailed into the strait that now bears Davis' name. In 1616, William Baffin and Robert Bylot sailed up Davis Strait and around the great channel that has ever since been known as Baffin Bay. Russia, the Netherlands, and Denmark took an interest in the search.

By the late 1700's, the territory that had been explored included Hudson Strait, Hudson Bay, Davis Strait, Baffin Bay, and the icy seas from Greenland to Svalbard and from Svalbard to Novaya Zemlya. See **Exploration**.

Commander John Ross, a Scottish explorer, began the final series of expeditions in 1818. The most noted of the explorers to follow him was Sir John Franklin, a British explorer. Franklin found a passage to Asia during a voy-

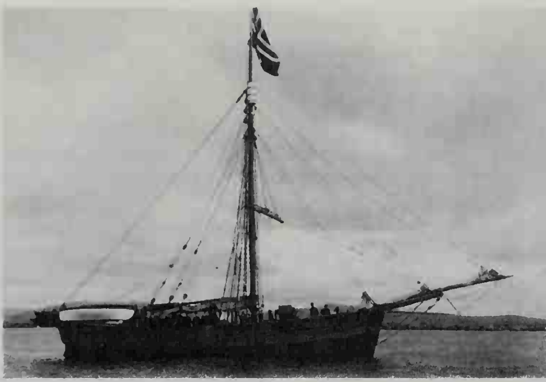
ge from 1845 to 1847. His ships reached King William land, near waters that led directly to the Asian shore. owever, Franklin and his crew died after their ships ecame jammed in the ice, and their discovery was not nown until later expeditions found relics of their trip. In 350, Sir Robert McClure, a British explorer, sailed rough a passage to the northern shore of what is now anks Island. Thick ice halted his voyage. But McClure nd his crew continued by sled and ship and, in 1854, ompleted the first journey through the Northwest Pas- ıge.

In 1906, Roald Amundsen's ship, the *Gjöa,* completed e first trip through the Northwest Passage. Amundsen aveled from east to west. The first west-to-east voyage as completed in 1942 by the Royal Canadian Mounted Police schooner *St. Roch.*



McClure Strait was conquered in 1954 by United States Navy and Coast Guard icebreakers. Three U.S. Coast Guard cutters, the *Spar,* the *Bramble,* and the *Storis,* aided by the Canadian Navy icebreaker the *Labrador,* made the west-to-east trip in 1957. They traveled through Bellot Strait. This channel permits cargo ships to unload supplies for the North Warning System radar line in northern Canada. The *Spar* was the first ship to sail completely around North America on a continuous voyage. It started in Bristol, Rhode Island, went south to the Panama Canal, then up the Pacific Coast, through the Northwest Passage, and back to Bristol.

In 1960, the U.S. atomic submarine *Seadragon* made the first underwater crossing of the Northwest Passage.

Colored lithograph (1854) by Lt. S. Gurney Cresswell; Peabody Essex Museum, Salem, MA

The *Investigator,* a ship captained by the British explorer Sir Robert McClure, sailed to the north shore of Banks Island in 1850. There, thick ice prevented further sailing. But McClure and his crew continued by sled and ship, completing the first expedition through the Northwest Passage in 1854.

Bancroft Library, University of California, Berkeley

Roald Amundsen's ship, the *Gjöa*, *left,* sailed through the Northwest Passage from 1903 to 1906, becoming the first ship to complete the journey. A weary Amundsen, standing far left in the picture on the right, posed with the ship's crew after arriving in Nome, Alaska.

It traveled 850 miles (1,368 kilometers) from Lancaster Sound, through the Canadian Arctic islands, and into McClure Strait. In 1969, the U.S. icebreaker-tanker *Manhattan* became the first commercial ship to complete the passage. The *Manhattan* sailed to Alaska by way of the Prince of Wales Strait. William Barr

Northwest Territories is a vast region in northern Canada. It stretches from the northern boundaries of the provinces of British Columbia, Alberta, and Saskatchewan north to islands in the Arctic Ocean. It lies between the Yukon Territory in the west and the territory of Nunavut in the east. Until April 1, 1999, Nunavut had been part of the Northwest Territories.

The Northwest Territories is sparsely populated. Its people include Inuit, Indians, people of European descent, and *métis* (people of mixed European and Indian ancestry). Yellowknife is the capital.

The land

The Northwest Territories has two geographic areas: the Mackenzie Valley and the High Arctic. The tree line, the northern limit of forest growth, separates the Mackenzie Valley and the High Arctic.

The Mackenzie Valley area lies east of the Yukon Territory and south of the tree line. A majority of the people of the Northwest Territories live in the Mackenzie Valley area. This geographic region includes the rugged Mackenzie Mountains, which rise along the length of the Yukon boundary from British Columbia in the south to the Beaufort Sea in the north. High peaks include Mount Sir James MacBrien (9,062 feet, or 2,762 meters) and Dome Peak (9,000 feet, or 2,743 meters).

iver Valley itself, a northward continuation of the Great entral Plain of North America. The Mackenzie River is ıe longest river in Canada and one of the largest water-heds in North America. The river flows northwest for ,100 miles (1,770 kilometers) from Great Slave Lake to ıe Beaufort Sea. Communities on the banks of the Mackenzie River include Fort Simpson, Norman Wells, ort Norman, Fort Good Hope, and Inuvik. Birch, larch, ine, poplar, and spruce trees are common in the area, which serves as a source of forest products.

East of the Mackenzie River are the Franklin Moun-ıins, which rise to elevations of about 5,000 feet (1,500 meters). Two of the largest lakes in Canada, Great Bear Lake and Great Slave Lake, lie east of the Franklin Mountains. The capital city of Yellowknife stands on the shores of Great Slave Lake.

acts in brief

apital: Yellowknife.

overnment: *Parliament*—members of the Senate, 1; members of the House of Commons, 1. *Territorial*—members of the territorial Legislative Assembly, 14.

hief products: *Fishing industry*—lake trout, whitefish. *Manufacturing*—food products, printed materials. *Mining*—diamonds, petroleum, gold.

To the southwest of the Mackenzie River is the World Heritage Site of Nahanni National Park. World Heritage sites have been chosen by the United Nations Educational, Scientific and Cultural Organization (UNESCO) as areas of unique natural or cultural importance. The park features towering mountains and thundering waterfalls. Wood Buffalo National Park, another World Heritage Site, extends into the province of Alberta from the southern part of the Territories. One of the largest herds of buffalo in Canada roams the park, and whooping cranes nest there in the spring.

The High Arctic region of the Northwest Territories lies north of the tree line and includes several islands in the Arctic Ocean. Much of the area is covered by a rolling, rocky terrain called *barrenlands,* which is dotted with lakes and rivers. The vegetation there consists of shrubs and small trees. The chief communities of the High Arctic include Holman, Sachs Harbour, Tuktoyaktuk, and Paulatuk. The Inuvialuit people, also called the Mackenzie Inuit, make up most of the population of the High Arctic in the Northwest Territories.

Climate

The Northwest Territories has long, cold winters and short, cool summers. Summers in the Mackenzie Valley

region are warmer than those in the High Arctic area. Inuvik, in the Mackenzie Valley area, has average temperatures of 56 °F (13 °C) in July and −18 °F (−28 °C) in January. Temperatures in Fort Smith, in the far south, average 61 °F (16 °C) in July and −13 °F (−25 °C) in January. The High Arctic area has an average July temperature of about 52 °F (11 °C), and January temperatures range around −25 °F (−32 °C). The highest temperature recorded in the Northwest Territories was 103 °F (39 °C) at Fort Smith on July 18, 1941. The lowest, −71 °F (−57 °C), also occurred there, on Dec. 26, 1917.

There are 20 hours of daylight each day in June in the southern Northwest Territories. The northern Northwest Territories is in the "land of the midnight sun." There, daylight lasts 23 hours a day for most of June and July.

Most of the Territories receives little moisture. The average annual precipitation is 11 inches (27 centimeters). Most of it falls as snow. About 60 inches (150 centimeters) of snow falls every year on the mainland and less than 40 inches (100 centimeters) on many islands.

People

Indians, Inuit, and métis make up nearly half the population. Most of the rest of the people are of European descent. The various Indian groups in the area refer to themselves together as *Dene,* which means *people.* Individual Indian groups in the Territories include the Bear Lake Indians, also called the Sahtu Gotine; the Chipewyan; the Dogrib; the Gwich'in, also called the Kutchin; the Hare; and the Slavey. The Inuit of the Northwest Territories are often referred to as the Inuvialuit.

The Northwest Territories has about 35 scattered communities. Yellowknife is the only city in the region and the largest populated center. Fort Smith, Hay River, Inuvik, and Norman Wells are incorporated towns.

Economy

Mining contributes more to the economy of the Northwest Territories than any other economic activity. Diamonds rank as the region's leading mined product. In 1998, the first diamond mine in Canada was officially opened near Lac de Gras, about 186 miles (300 kilometers) north of Yellowknife.

Oil, which ranks second, is produced at a field near Norman Wells. Natural gas deposits have been found in the Mackenzie Delta and the Liard Valley. Gold ranks third among the mined products of the Northwest Territories. Gold mining is centered in the Yellowknife area.

Government service. A major employer in the Northwest Territories is government. About one-seventh of the population is employed in the federal, territorial, or municipal governments.

Tourism is becoming an increasingly important part of the economy of the Northwest Territories. People visit the Territories to enjoy its rugged natural beauty and to engage in such activities as hunting and skiing. Many tourists also come to the Northwest Territories during the winter months to observe the natural display of lights in the sky called the *aurora borealis* or *northern lights.* See Aurora.

Fishing industry. Almost all commercial fishing in the Territories is carried out on Great Slave Lake. The lake supplies whitefish and lake trout.

Forest industry. Forest products from the Northwest Territories come mainly from birch, pine, poplar, and spruce trees. Sawmills are south of Great Slave Lake at Fort Resolution, Hay River, and Fort Liard.

Transportation. Great distances and a small number of passengers make transportation expensive in the Northwest Territories. The cheapest and oldest form of transportation in the area is by water. But the main water route, the Mackenzie River, is frozen for eight to nine months each year. A tug and barge service operates from the Hay River terminal of the Mackenzie Northern Railway on Great Slave Lake. The route continues along the Mackenzie River to the Beaufort Sea. Barges on the Slave and Athabasca rivers operate in the far south.

Scheduled air services operate in both the Mackenzie Valley and the High Arctic. Seaplanes take supplies to mining and prospecting communities. Jet aircraft serve Fort Smith, Hay River, Inuvik, Norman Wells, and Yellowknife. The Mackenzie Northern Railway provides

Yellowknife is the capital and largest city of the Northwest Territories of Canada. It lies on Yellowknife Bay, a projection at the northern end of Great Slave Lake.

Wilhelm Schmidt, Masterfile

\n oil rig drills for petroleum near Norman Wells, on the /lackenzie River. Petroleum production is an important eco- omic activity in the Northwest Territories.

reight service between Alberta and Hay River. The rail- oad runs parallel to the Mackenzie Highway. Most of ne region's highways are paved. Temporary ice roads erve as winter supply routes for some communities.

Communication. Newspapers are published in most f the main Northwest Territories communities. The Canadian Broadcasting Corporation has radio stations in ellowknife and Inuvik. A telecommunications satellite ystem provides radio, telephone, and television to all ommunities in the Territories.

Education

Schools in Yellowknife are operated by two district ducation authorities—public and Roman Catholic. In ne rest of the Territories, regional education boards co- rdinate the activities of the schools within the bound- ries of their authority. For the number of students and achers in the Territories, see **Education** (table).

Aurora College is the only college in the Northwest erritories. It has campuses in Fort Smith, Inuvik, and ellowknife. The territorial government provides grants nd loans for Northwest Territories students who wish attend Aurora College or universities and colleges utside of the Territories.

Government

The people elect one member to the Canadian House Commons. The Northwest Territories has one repre- entative in the Canadian Senate.

The federal government appoints a commissioner to erve as honorary head of government for the Territo- es. A premier actually leads the government. The premier heads an Executive Council (cabinet). The Legislative Assembly of the Territories elects the premier and the council from among its own members.

The 14 members of the Legislative Assembly are elected to four-year terms. The Assembly governs by *consensus*—that is, by general agreement. The Northwest Territories has no political parties. The territorial government has branch offices in several communities throughout the Territories.

The court system of the Territories includes the Court of Appeal, the Supreme Court, and the Territorial Court. The Court of Appeal handles appeals of criminal and civil cases from the Supreme and Territorial courts. It consists of three judges, all of whom are appointed by the federal government. The Supreme Court tries various civil and criminal cases and hears appeals of some cases from the Territorial Court. The Supreme Court consists of a senior justice and two other justices. The federal government appoints all three of the justices. The Territorial Court handles cases involving small claims, young offenders, and criminal law. It also has some authority over family law cases. Its three judges are appointed by the commissioner of the Territories.

The Northwest Territories has several *settlement areas* that have been set up as a result of land claim agreements with *aboriginal peoples*—that is, the Inuit and Indians—and métis. In general, these agreements recognize aboriginal control over the lands in the settlement areas. The agreements also call for the establishment of *resource boards* in the areas. These boards include government representatives and representatives of the aboriginal peoples. They enact measures concerning a number of issues, including the management of land, water, and wildlife in the settlement areas. Settlement areas in the Territories include the Inuvialuit, Gwich'in, and Sahtu regions.

History

Inuit and Indians lived in the Northwest Territories for thousands of years before Europeans arrived. The first white person to cross the Territories by land was Samuel Hearne of the Hudson's Bay Company, a British fur-trading firm. He set out in 1770 from Churchill in present-day Manitoba. Traveling overland, he reached the mouth of the Coppermine River in 1771 and explored the Great Slave Lake region on the return journey. In 1789, Alexander Mackenzie reached the river that now bears his name.

Creation of the Northwest Territories. In 1870, the Canadian government organized two newly acquired regions—Rupert's Land and the North West Territory—into the North West Territories, which later became known as the Northwest Territories. The Canadian government then became responsible for the administration of the region. The eastern part of the North West Territories—that is, Rupert's Land—had belonged to the Hudson's Bay Company since 1670. The North West Territory lay north, west, and south of Rupert's Land.

The Territories lost part of the Manitoba area in 1870, when Manitoba became a province. The Yukon Territory was cut off in 1898, and the provinces of Alberta and Saskatchewan in 1905. In 1912, Manitoba, Ontario, and Quebec acquired certain areas.

The early and middle 1900's. The discovery of radi-

Symbols of the Northwest Territories

The territorial flag

The territorial coat of arms

The floral emblem
Mountain avens

The territorial flag, which bears most of the coat of arms, was adopted in 1969. On the coat of arms, the wavy blue line represents the Northwest Passage. The gold bars symbolize the Territories' mineral wealth. The white fox represents the fur industry. Two *narwhals* (arctic whales) guard a compass rose, which symbolizes the magnetic north pole. The coat of arms was adopted in 1957.

um ore on the shore of Great Bear Lake in the early 1930's brought the Northwest Territories into world prominence. During World War II (1939-1945), the importance of the radium mine increased because of the demand for uranium, which is found in the same ore as radium. Also, the requirements of the Allied armies brought about an intensified program for the building of airfields and weather stations in the Territories.

The Canadian government did little to develop the Territories until after World War II. Then it increased the number of the Royal Canadian Mounted Police detachments and began to establish weather stations, post offices, schools, and medical services.

The government expanded its programs for education and medical and social welfare during the 1950's. Interest in mineral and oil exploration also increased. Scheduled airplane flights to the Mackenzie Valley area and Baffin Island, at that time a part of the Northwest Territories, began in the 1950's.

In the 1960's, Canada's government carried on a major roadbuilding program. A railway was constructed from Peace River, Alberta, to Great Slave Lake in the mid-1960's to serve mining operations that lasted for a time in Pine Point. In 1967, Yellowknife became capital of the Territories. The federal government began transferring its administrative responsibilities in the Northwest Territories to the territorial government in Yellowknife.

Recent developments. For many years, Inuit of the Northwest Territories called for their own political unit in the east. In 1982, the people voted to divide the Territories into two political units—eastern and western territories. In 1992, the people of the Northwest Territories voted and approved a boundary to divide the territories. The Inuit territory, in the east, was to be called Nunavut. In 1993, the Canadian Parliament approved the division of the Northwest Territories and passed legislation to create Nunavut. The new territory came into being on April 1, 1999. With the creation of Nunavut, the size of the Northwest Territories shrank from 1,322,910 square miles (3,426,320 square kilometers) to 501,570 square miles (1,299,070 square kilometers). Northwest Territory was a vast tract of land lying north of the Ohio River, west of Pennsylvania, and east of the Mississippi River. It extended to the northern limits of the United States. The states of Ohio, Indiana, Illinois, Michigan, Wisconsin, and part of Minnesota east of the Mississippi were carved out of the Northwest Territory.

Early history. The French, who first occupied the region, had established posts by the early 1700's. Competition between French traders operating from these posts and British trappers from Pennsylvania helped start the French and Indian War (1754-1763). The war ended with the cession of the area to a victorious United Kingdom. See **French and Indian wars**.

During the Revolutionary War (1775-1783), violent fighting took place in the Northwest between the settlers and the British and their Indian allies. The campaign of George Rogers Clark against British-controlled settlements helped win the territory for the United States. The region was ceded after the war. Before the government could open the region to settlement, it had to deal with the claims of Massachusetts, Connecticut, Virginia, and New York. These states insisted that their colonial charters extended their boundaries into this area. The states ceded their claims to Congress between 1781 and 1785, because Maryland refused to approve the Articles of Confederation until it received assurance that the other states would yield their claims.

The land then became a territory of the United States.

Granger Collection
The Northwest Territory's first settlement and its first capital was established at Marietta, Ohio, in 1788. The engraving of the Marietta courthouse and jail shown here dates from 1842.

Congress, eager for revenue from the sale of lands there, adopted the Ordinance of 1785. This law provided for orderly rectangular surveys into mile-square units called *sections.* These were sold at auction at a minimum price of $1 an acre. Congress also struggled with the problem of a government for the territory. Thomas Jefferson in 1784 had drafted a plan that would have divided the territory into several units. These could become states when the population of any one unit equaled the population of the smallest state in the Union. The Eastern States rejected this proposal, because they feared that the many Western States would dominate Congress. Instead, Congress adopted the Northwest Ordinance, or Ordinance of 1787. This provided for the division of the region into from three to five states, and the establishment of a governmental system that would allow them eventual membership in the Union. See **Northwest Ordinance.**

Settlement began at once. The first arrivals were sent out by a New England speculating group called the Ohio Company (see **Ohio Company**). They founded the town of Marietta at the mouth of the Muskingum River in Ohio. Other interests soon established rival settlements at such villages as Gallipolis and Cincinnati. To the north, colonists clustered about Cleveland in the "Western Reserve" area retained by Connecticut when it ceded its lands to Congress (see **Western Reserve**). Arthur St. Clair became the first governor of the Northwest Territory in 1787. He inaugurated the first territorial government on July 15, 1788.

The population grew slowly at first because of continued Indian attacks. President George Washington sent three expeditions to fight the Indians, but the first two met with disaster. The territory became more peaceful after General Anthony Wayne defeated the Indians in the Battle of Fallen Timbers in 1794. In 1795, Wayne forced the Treaty of Greenville on the defeated Indians. In the Treaty of Greenville, the Indians ceded most of the lands of southern Ohio and part of eastern Indiana to the United States. Other land cessions followed during the early 1800's. See **Indian wars** (Along the frontier).

As more settlers moved into the region, the Northwest Territory was divided. In 1800, the western part of the region became the Territory of Indiana, with William Henry Harrison as governor. The Michigan Territory was created in 1805, and the Illinois Territory in 1809. Ohio became a state in 1803, Indiana in 1816, Illinois in 1818, Michigan in 1837, and Wisconsin in 1848.

Northwestern University is a private coeducational institution with campuses in Evanston and Chicago, Illinois. The main campus, in Evanston, has a college of arts and sciences; schools of education and social policy, engineering and applied science, journalism, music, and speech; a graduate school; and a graduate school of management. The Technological Institute and the National High School Institute are also at the Evanston campus. Northwestern grants bachelor's, master's, and doctor's degrees.

The Chicago campus serves as a center for professional studies. The McGaw Medical Center, one of the world's largest private medical centers, is based there. It includes the university's dental and medical schools, and has five member hospitals in the Chicago area—Children's Memorial Hospital, Evanston Hospital, Northwestern Memorial Hospital, the Rehabilitation Institute of Chicago, and the Department of Veterans Affairs Lakeside Medical Center. The university's law school and its University College are also on the Chicago campus. The University College offers summer and continuing education courses and some degree programs.

Northwestern was the first university in the United States to establish a school of speech and to sponsor a children's theater. Its law school was the first to organize a scientific crime detection laboratory. The university also established the first program in African studies. Its Center for Materials Science, Center for Urban Affairs, and Transportation Center are nationally known.

Northwestern University was founded in 1851. The Chicago campus opened in 1926.

Critically reviewed by Northwestern University

Norton, Andre (1912-), is an American author of science fiction. She has written more than 100 books, most of them for young people. Norton often draws on history and folklore for her action-packed plots, which include such elements as magic, time travel, and animals with powers of telepathy.

Norton's first books were spy stories and historical novels. Her first science-fiction book was *Star Man's Son, 2250 A.D.* (1952). Other books include *The Beast Master* (1959), *Operation Time Search* (1967), *Wraiths of Time* (1976), and *Dare to Go A-hunting* (1990).

Norton was born in Cleveland. From 1932 to 1951, she worked as a children's librarian there. Norton's given name was Mary Alice. She changed her name to Andre because of concerns that her first novel, *The Prince Commands* (1934), would not be accepted if publishers knew its author was a woman. Norton has also written science fiction under the pen name Andrew North.

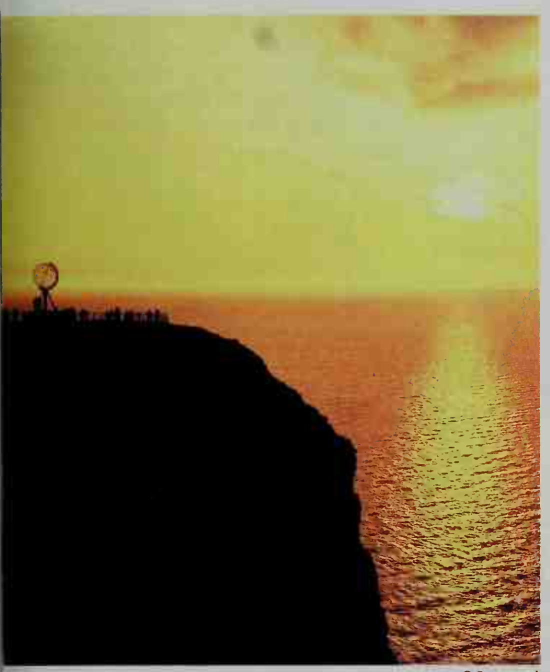
Norway is known for the scenic beauty of its rugged mountains and its deeply indented coast. Many inlets of the sea called *fiords* extend far into the country. The village of Stryn on the Nord Fiord, *shown here,* lies about 60 miles (100 kilometers) from the coast.

Norway

Norway is a long, narrow country on the northwestern edge of the European continent. The northern third of Norway lies above the Arctic Circle and is called the *Land of the Midnight Sun.* Because this region is so far north, it has long periods every summer when the sun shines 24 hours a day. Oslo, Norway's capital and largest city, is in the southern part of the country.

Most of the Norwegian people live near or along the sea. Winds warmed by the sea give the coast much warmer winters than other regions so far north, and snow melts quickly there. Even north of the Arctic Circle, nearly all of Norway's harbors are free of ice the year around. Inland areas are colder, and snow covers the ground much of the year. For thousands of years, the people have used skis for travel over the snow. Today, skiing is Norway's national sport. Most Norwegians learn to ski before they even start school.

Norway, along with Denmark and Sweden, is one of the Scandinavian countries. Vikings lived in all three countries about a thousand years ago. Vikings from Norway sailed west and established colonies in Iceland and Greenland. About A.D. 1000, Leif Ericson sailed from Greenland and headed what was probably the first European expedition to the mainland of America.



Since the time of the Vikings, the Norwegians have been a seafaring people. Norway's coast is famous for its many long, narrow inlets of the sea called *fiords,* which provide fine harbors. Rich fisheries lie off the west coa[st] and dried fish were an important export as early as the 1200's. Norway began developing its great shipping fle[et] during the 1600's. Today, Norway's fishing and shippin[g] industries rank among the world's largest.

Norway is mostly a high, mountainous plateau covered by bare rock, and it has a relatively small amount [of] farmland. But the rivers that rush down from the moun[tains]

Oslo, Norway's capital and largest city, is home to almost 1 of 8 Norwegians. Oslo is also the chief commercial, industrial, and shipping center of Norway.

ıins provide cheap electric power. Norway generates ıore hydroelectric power per person than any other ountry. Norwegian manufacturing is based on this heap power.

The Norwegian flag was first approved for use by merchant ships in 1821. It became the national flag in 1898.

Norway's coat of arms dates from the 1280's, when the ax and crown of Saint Olav were added to the lion.

Government

Norway is a constitutional monarchy with a king or a ueen, a Cabinet led by a prime minister, and a parliaıent. The government is based on the Norwegian Conititution of 1814, which divides the government into ıree branches—executive, legislative, and judicial. The rime minister is the actual head of the government. The ıonarch has little power.

The monarch usually appoints the leader of the rongest political party or *coalition* (group of parties) in ıe parliament to be prime minister. Other high governıent officials, including judges and county governors, e appointed by the monarch on the advice of the Cabiet. Like the other Scandinavian countries, Norway has a overnment official called an *ombudsman.* This official ıvestigates complaints by citizens against government ctions or decisions. See **Ombudsman.**

National government. Executive power in the Noregian government is exercised by the Cabinet, also ıown as the Council of State. It consists of the prime inister and about 18 other officials, each of whom eads a department or ministry. The monarch officially ɔpoints the Cabinet members, but they are actually sected by the party or coalition in power in the parliaent. To keep the powers of the executive and legislaʻe branches separate, Cabinet members cannot also

e members of the parliament.

The Cabinet is responsible for forming government olicies. A Cabinet remains in office as long as it has the upport of a majority of the parliament. The Cabinet ıust resign if it loses a vote of confidence in the parliaıent. If a vote of no confidence or some other governıent crisis occurs, an alternate Cabinet—usually from minority party—is appointed to govern during the rest f the parliament's term.

The parliament, Norway's lawmaking body, is called ıe Storting. It consists of 165 members elected to fourear terms. Each of Norway's 19 counties elects 4 to 15 ıembers, depending on its population. An additional ight members are chosen from national electoral lists. he Storting consists of one house. But after each elecon, its members form two sections to discuss and vote n proposed laws. They elect 39 of their number to the agting. The remaining 126 members make up the delsting.

To become law, most bills must first be approved by ıe Odelsting and then by the Lagting. If the two secons do not agree on a bill, it can be approved by twoirds of the parliament as a whole. Certain matters, inuding bills that deal with taxation and spending, are oted on only by the entire parliament.

Courts. Norway's highest court is the Supreme Court f Justice. Five Superior Courts try the most serious cass and hear appeals of decisions made by the county nd town courts. Each county and town also has a Conliation Council, which tries to settle disputes before ıey go to court. This body consists of three people lected to four-year terms.

Local government. Norway has 19 counties, one of hich is the city of Oslo. Each of the counties, except slo, has a governor. Norway's cities, towns, and village istricts elect councils of varying size to four-year terms. hese councils select a chairman, or mayor, who serves vo years.

Politics. Norway has several major political parties. he largest is the socialist Labor Party. Members of the ıbor Party favor social welfare programs, and they also ıvor government action to foster economic growth and ıll employment. The Conservative Party's members ıpport lower taxes and less government control of the conomy. The Christian People's Party is a center right arty whose members promote democracy based on a hristian outlook.

Norway's other major political parties include the enter Party, the Liberal Party, the Progress Party, and ocialist Left Party. All Norwegians who are at least 18 ars old can vote.

Armed forces. Norway's army, navy, and air force ıve a total of about 34,000 troops. Norwegian men beveen the ages of 19 and 44 are required to serve from ! to 15 months in the armed forces. About 85,000 men ıd women serve in the Home Guard.

People

Ancestry. The Norwegians are a Scandinavian peoe, closely related to the Danes and the Swedes. The ople of Norway have strong ties with Americans. om the mid-1800's to the early 1900's, more than 0,000 Norwegians migrated to the United States in arch of better job opportunities.

About 40,000 Sami, formerly known as Lapps, live in far northern Norway (see **Sami**). That region also has about 10,000 people of Finnish ancestry. Norway also has many immigrants. They include people from Iran, Pakistan, and Turkey, and from Africa, the United States, Southeast Asia, and from other European nations.

Language. The Norwegian language has two forms—Bokmål and Nynorsk. They are similar enough for someone who speaks either form to understand a person who speaks the other. Both Bokmål and Nynorsk belong to the Scandinavian group of Germanic languages. Local school boards may select either as the chief form in a school, but all students learn to read both. The Sami also use their own language, which is similar to Finnish.

Bokmål, also called Riksmål, is the major form used in the cities and towns, and in most Norwegian schools. Bokmål is a Norwegian form of Danish. It has almost the same vocabulary and spelling as Danish, but is pronounced much differently. Bokmål developed during Norway's political union with Denmark, which lasted from 1380 to 1814. During that period, it replaced Old Norse, the early Norwegian language.

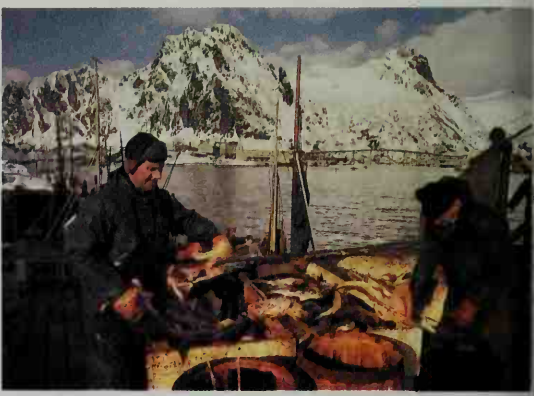
Nynorsk, originally called Landsmål, was created during the mid-1800's as a reaction against the Danish influence. Nynorsk was based on the many *dialects* (local forms of speech) that developed in rural areas during Norway's union with Denmark.

Way of life

City life. About three-fourths of Norway's people live in urban areas. But Norway is less urban than Denmark and Sweden, where about four-fifths of the people live in cities. Oslo, Norway's capital and largest city, has about half a million people. Other large cities include Bergen, Drammen, Kristiansand, Stavanger, Tromso, and Trondheim. See the articles on Norwegian cities listed in the *Related articles* at the end of this article.

Norwegian cities sprawl into surrounding suburbs, but they are smaller than most other European cities. They have fewer high-rise commercial buildings and lack the fast pace of life often found in cities of other industrial nations.

Norway's high standard of living and its social welfare system have kept the cities free of slums and substandard housing. Most Norwegians and immigrant workers live in modern apartment buildings in or near the principal urban areas. Wealthier Norwegians often own single-family homes built of wood. A number of Norwegians also own small cottages along the coast or in the mountains, which they visit on weekends or holidays.



Although Norway's cities have bus and train services, traffic congestion is a problem. Norway has little industrial pollution because of its extensive use of hydroelectric power and natural gas in industry. Unemployment is extremely low by international standards. Many of Norway's immigrants work in low-paying jobs in the cities. Their presence has caused discontent among some Norwegians because of the benefits the immigrants get through the social welfare system.

Rural life. About a fourth of Norway's people live in rural areas. The rural population is concentrated in southeastern Norway, which has gently rolling hills suitable for farming, along the western coast, and in the northern regions. Many people who live in rural areas

Mittet Fo

Norwegian fishermen process a catch of fish. The fishing industry provides a livelihood for many rural Norwegians.

fish for a living. Some spend weeks or even months away from home on fishing ships in the North Sea and the North Atlantic Ocean.

Many rural homes are old, wooden farmhouses that have been modernized. Almost all of them have electric stoves, refrigerators, and other appliances.

Norway's numerous fiords, rivers, and mountains prevent many rural Norwegians from traveling easily. However, roads and tunnels built since the late 1900's have helped connect parts of Norway that had been isolated. Snow and ice still make many roads impassable during much of the year. For these reasons, rural people rely heavily on boats and the country's electrified railway system for transportation.

Food and drink. Norwegians usually eat four meals a day, but many farm families have five. Breakfast generally includes cereal and open-faced sandwiches with cheese, jam, herring, marmalade, or sliced meat. Goat cheese is a favorite sandwich spread. Sandwiches are also eaten at lunch and at a late-evening supper. Dinner is usually the only hot meal of the day. It includes soup, meat or fish, potatoes, vegetables, and dessert. People in the cities and towns eat dinner in the evening. Some people in farm areas have dinner at midday.

Norwegians drink coffee throughout the day and especially at mealtimes. Many Norwegians also enjoy beer, which is sometimes served with a strong, colorless liquor called *aquavit.* Tea, milk, and soft drinks also are popular in Norway.

Recreation. Outdoor sports are an important part of Norwegian life. Recreation areas lie within short distances of all homes. Skiing, Norway's national sport, ma have started there thousands of years ago as a means o crossing the snow-covered land. Many Norwegians tak cross-country ski trips to the country's mountains or wooded hills. Almost every town has a ski jump. The second most popular winter activity is ice-skating. Norwegians also have long enjoyed *bandy,* a form of hockey played by 11-player teams on large rinks. Soccer is the favorite summer sport.

Norway's forests and mountains provide many other recreational opportunities. On weekends, many Norwegians enjoy hiking through hills and forest areas. Some Norwegians travel to cabins in the mountains, where

hey may spend several weeks during the summer vaca- ion season. Many adults also enjoy hunting. Sailing is popular along the coast. In addition, Norway's numerous fiords, lakes, and rivers attract many fishing enthusiasts. Swimming is also a popular activity.

Social welfare. The government of Norway provides he people with many welfare services. All families with more than one child receive a yearly allowance for each youngster under the age of 16, beginning with the second one. These families also may receive financial aid in paying their rent. The government guarantees all employed people an annual four-week vacation with full pay. Large families with medium or low incomes pay little or no national taxes, and their local taxes are reduced.

The National Insurance Act, which went into effect in 1967, combined many existing welfare programs. All Norwegians are required to take part in this combined plan. It includes old-age pensions, job retraining, and aid for mothers, orphans, widows, widowers, and people with disabilities. Another insurance plan provides free medical and hospital care, plus cash payments to employees during illness. The costs of these plans are shared by the insured people, their employers, and the national and local governments.

Religion. The Norwegian Constitution establishes the Evangelical Lutheran Church as the nation's official church, but other religions have complete freedom of worship. About 88 percent of the people are Evangelical Lutherans. The government largely controls the Evangelical Lutheran Church. It appoints the pastors and church officials and pays their salaries.

Other religious groups in Norway include Baptists, Free Lutherans, Methodists, Pentecostals, and Roman Catholics. The Oslo region is home to a large Muslim community.

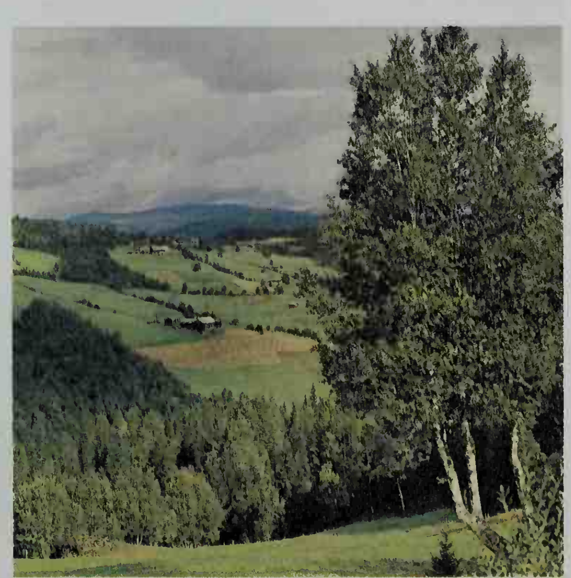
Education. Almost all people in Norway can read and write. Norwegian law requires children from the age of 7 to 16 to go to school. The elementary school program lasts six years. It is followed by three years of junior high school and three years of senior high school. Senior high school provides academic courses for those who wish to go on to college and also vocational courses.

Bergen, Oslo, Tromsø, and Trondheim each have a university. Schools of higher education also include a network of regional colleges, and several technical and other specialized institutions.

The University of Oslo Library is the largest library in Norway. Oslo also has the country's largest city library. All cities and towns are required by law to have free public libraries. These libraries are partly supported by government grants.

Arts. Norwegians have contributed much to the development of the arts. Henrik Ibsen's realistic plays of the late 1800's brought him worldwide fame as the father of modern drama. Three Norwegian writers—Bjørnstjerne Bjørnson, Knut Hamsun, and Sigrid Undset—have won the Nobel Prize for literature.

The painter Edvard Munch was a strong influence on the Expressionist art style of the early 1900's. Statues by Gustav Vigeland, perhaps Norway's greatest sculptor, stand in Oslo's Frogner Park. Edvard Grieg, Norway's best-known composer, used melodies from Norwegian folk songs and dances in his orchestral works. For more information on Norwegian artists, see the biographies listed in the *Related articles* at the end of this article.



The land

Land regions. Most of Norway is a high, mountainous plateau. Its average height is more than 1,500 feet (457 meters) above sea level. Only about a fifth of Norway, including two major lowlands, lies lower than 500 feet (150 meters). Norway has three main land regions: (1) the Mountainous Plateau, (2) the Southeastern Lowlands, and (3) the Trondheim Lowlands.

The Mountainous Plateau is covered largely by bare rock that was smoothed and rounded by ancient glaciers. Glaciers also formed many lakes and deep valleys, especially in the 4,500-square-mile (11,700-square-kilometer) Hardanger Plateau, Europe's largest highland plain. In Norway's uplands above 6,500 feet (1,980 meters), permanent snow and ice cover about 1,200 square miles (3,110 square kilometers). The 188-square-mile (487-square-kilometer) Jostedal Glacier is the largest ice field in Europe outside Iceland.

In the narrow northern half of Norway, the Kjølen mountain range extends along the border with Sweden. Norway's highest mountains rise in the wider southern half of the country. The Dovre Mountains extend in an east-west direction, and the Long Mountains rise to the south. The Jotunheimen range of the Long Mountains includes Galdhøpiggen, northern Europe's tallest mountain, which rises 8,100 feet (2,469 meters).

The Southeastern Lowlands consist mostly of the middle and lower valleys of the Glåma River, which is 372 miles (598 kilometers) long, and several other rivers. The rivers are used to float timber to pulp mills and sawmills. Their many waterfalls provide hydroelectric energy. The region also has narrow lakes, including Lake Mjøsa. Slopes are gentler than in most of the country, and the region is more suitable for farming and

Ernst A. Weber, Photo Researchers

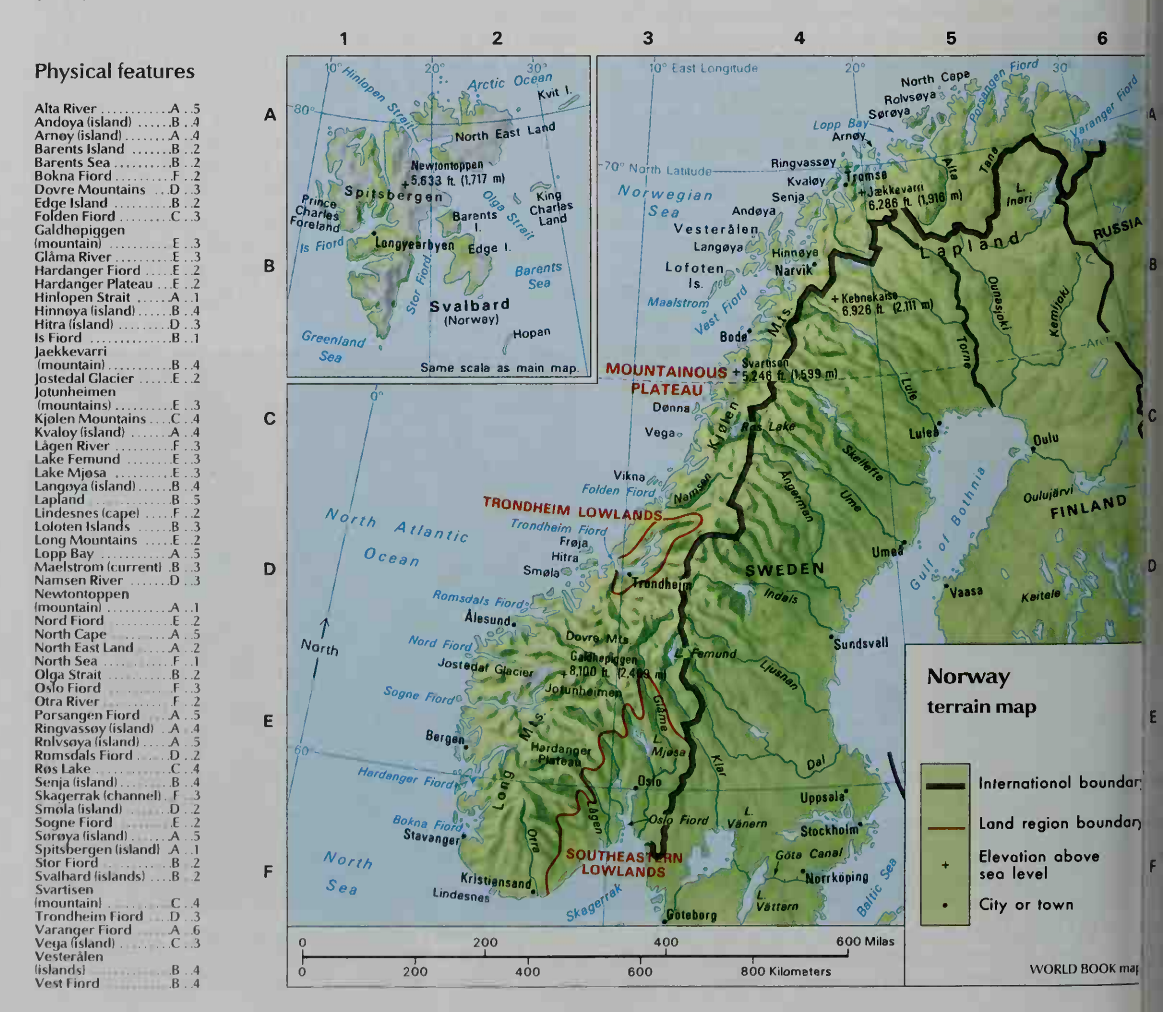
The Trondheim Lowlands include the lower ends of several wide, flat valleys that are suitable for farming. Crops include barley and potatoes. The region also has much dairy farming.

forestry. These lowlands are the most thickly settled part of Norway. They include Oslo, the capital and chief commercial, industrial, and shipping center.

The Trondheim Lowlands include the lower ends of several wide, flat valleys. In addition to providing good farmland, the valleys also serve as important railroad routes to other parts of Norway and to Sweden.

The lowlands have long been a major region of settlement. Trondheim, founded in A.D. 998, was an important religious center in Norway during the Middle Ages. Today, it is a leading center of industry and trade.

Coast and islands. Many long, narrow inlets of the sea indent the rocky coast of Norway. These inlets, called *fiords,* make the coastline one of the most jagged in the world. The longest, Sogne Fiord, extends inland for 127 miles (204 kilometers). Norway has a coastline of about 1,647 miles (2,650 kilometers). Including all the fiords and peninsulas, the full length of the coast is about 13,267 miles (21,351 kilometers), which is approximately half the distance around the world.



About 150,000 islands lie off the Norwegian coast. Some are only rocky reefs called *skerries,* which shield the coastal waters from stormy seas. The Lofoten and Vesterålen islands are the largest offshore island groups. The waters around them have rich cod fisheries. The famous Maelstrom current sweeps between the two outermost Lofotens, sometimes forming dangerous whirlpools. Jan Mayen and Svalbard are island possessions of Norway in the Arctic Ocean.

Climate

The climate of Norway is much milder than that of most other regions as far north, especially along the country's west coast. Near the Lofoten Islands, for example, January temperatures average 45 °F (25 °C) higher than the world average for that latitude. Snow that falls along the coast melts almost immediately. The warm North Atlantic Current of the Gulf Stream keeps nearly all the seaports ice-free, even in the Arctic (see **Gulf Stream**).

During winter, Norway's inland regions are colder than the coast because mountains block the warm west winds from the sea. Snow covers the ground at least three months a year. During the summer months, when the sea is cooler than the land, the west winds cool the coast more than the inland. The warmest summers are in the inland valleys of the southeast. Less rain falls inland than along the coast.

The far north, known as the *Land of the Midnight Sun,* has continuous daylight from mid-May through July. Th

period of midnight sun decreases southward, and there is no 24-hour sunshine south of the Arctic Circle. In winter, northern Norway has similar periods of continuous darkness. See **Midnight sun**.

Economy

Norway has a well-developed economy. In the last half of the 1900's, the nation's income from the production of goods and services increased sharply. Unemployment remained relatively low. The rapid economic growth resulted largely from government programs to promote investment and industries, and from increased foreign demand for the goods and services of Norway.

Natural resources. Norway's waters provide its most valuable resources. Important petroleum and natural gas fields lie offshore in the North Sea. The offshore areas and the country's rivers are rich in fish. Norway's many swift mountain rivers are used to produce hydroelectric power.

Norway's land is not rich in natural resources. About 60 percent of the country consists of mountains and plateaus that are covered mostly by bare rock. Only about 3 percent of Norway is farmland. Productive forests cover more than 20 percent of the land.

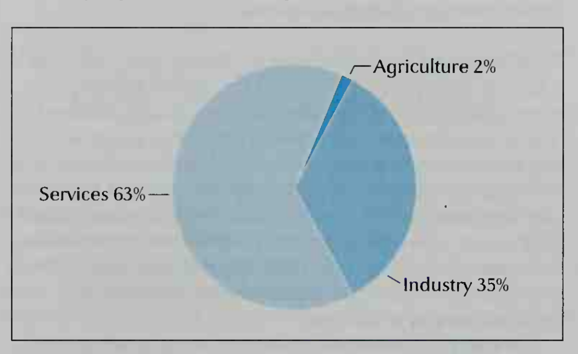
Service industries are those economic activities that provide services instead of producing goods. As in other industrial nations, Norway's service industries employ a growing number of workers. In the mid-1900's, employees in service industries accounted for about 45 percent of the work force. By the end of the 1900's, these activities employed close to 70 percent of Norway's workers.

Community, government, and personal services employ more than a third of Norway's workers and include such activities as education, health care, and government. Other service industries include banking, communication, insurance, trade, and transportation.

Mining became a major Norwegian economic activity during the 1970's, when the country began producing petroleum and natural gas from North Sea fields. Today, petroleum and natural gas account for a large part of the country's income. Iron ore and pyrites, from which copper and sulfur are taken, are mined in Norway. Other minerals include ilmenite, lead, molybdenite, and zinc. Coal is mined only in Svalbard, an island territory north of Norway.

Manufacturing developed much later in Norway than in the major industrial countries. Those countries had their own coal to provide power with which to run machines. In the 1800's, Norway had to import coal for its factories, which made manufacturing costly and held back its growth. By 1900, Norway had started to develop its sources of cheap hydroelectric power. The country's factories turned to hydroelectric power to meet their needs. As a result, manufacturing in Norway expanded rapidly.

Today, manufacturing is one of Norway's most valuable industries. The most important products include petroleum products, chemicals and chemical products, such metals as aluminum and magnesium, processed foods, and wood pulp and paper. Norway is an important aluminum-producing country. This metal is processed from imported bauxite. The nation also produces clothing, electrical machinery, furniture, and small ships.



Agriculture. Farms in Norway lie on narrow strips of land in inland valleys and along the coast. About two-thirds of the country's farms cover 25 acres (10 hectares) or less.

Many Norwegian farmers have a second occupation so they can earn enough to support their families. Farmers own about two-thirds of Norway's commercial forests, and many are also loggers. Some farmers also fish commercially.

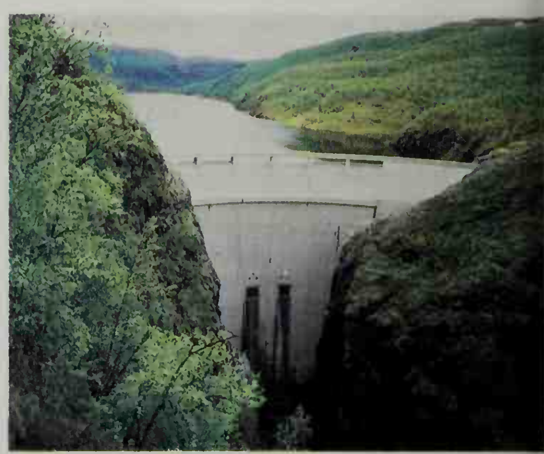
Dairy farming and livestock production account for over two-thirds of Norway's farm income. Most cropland is used to grow livestock feed. The major crops of Norway are barley, fruits and vegetables, hay, oats, and potatoes.

Fishing. Norway has long been a great fishing country. Its total catch is about 4 billion pounds (1.8 billion kilograms) a year. Norwegian fishing crews bring in

Norway's gross domestic product

Norway's gross domestic product (GDP) was $152,943,000,000 in 1999. The GDP is the total value of goods and services produced within a country in a year. *Services* include community, government, and personal services; finance, insurance, real estate, and business services; trade, restaurants, and hotels; and transportation and communication. *Industry* includes construction, manufacturing, mining, and utilities. *Agriculture* includes agriculture, forestry, and fishing.

Production and workers by economic activities



Economic activities	Percent of GDP produced	Employed workers: Number of people	Employed workers: Percent of total
Community, government, & personal services	24	825,000	36
Finance, insurance, real estate, & business services	18	252,000	11
Mining	16	*	*
Manufacturing	12	332,000	15
Trade, restaurants, & hotels	11	411,000	18
Transportation & communication	10	170,000	8
Construction	5	146,000	6
Agriculture, forestry, & fishing	2	102,000	5
Utilities	2	18,000	1
Total	100	2,256,000	100

large numbers of cod, haddock, herring, and mackerel. Much of the catch is processed for export. Norway's once-great whaling industry declined sharply during the 1960's. Large catches by Norway and other major whaling nations made many kinds of whales increasingly scarce. In 1987, Norway joined an international *moratorium* (temporary halt) on commercial whaling (see **Whale** [The future of whales]). It continued to take some whales for research purposes. In 1993, Norway resumed limited commercial whaling of minke whales, claiming they were no longer in danger.

Forestry has been an important industry in Norway for hundreds of years. Lumber became a major export in the 1500's. Today, much timber is also used to make pulp and paper. Commercial trees include birch, pine, and spruce. More than 12,000 miles (19,300 kilometers) of forest roads have been built to transport the logs. Much timber is also moved by way of rivers.

Norwegian loggers cut more than 350 million cubic feet (10 million cubic meters) of timber a year. The forest growth rate is about 670 million cubic feet (19 million cubic meters) a year. Timber production could not be increased much without using up the forests, all of which are protected by government regulations.

Energy sources. Since the early 1900's, hydroelectric stations have generated most of the power used in Norway's industry and homes. But since the mid-1970's, the extraction of Norway's rich oil and natural gas deposits in the North Sea has led to more extensive use of petroleum products in industry and transportation. About half of the energy Norway consumes is now generated by hydroelectric power. About 40 percent of the country's energy is produced by petroleum products, and about 10 percent by such solid fuels as coal, peat, and wood.

Foreign trade. Norway depends heavily on foreign trade to help keep its standard of living high. The nation's trade is one of the largest in the world in relation to its population. Norway, with limited natural resources, imports a wide variety of foods and minerals as well as manufactured goods. Petroleum and natural gas rank as Norway's chief exports. Other exports include chemicals, fish, machinery, metals, transportation equipment, and wood pulp and paper. Norway's merchant fleet, one of the largest in the world, is also an important source of income for the country. The fleet provides shipping services for countries in all parts of the world.

Norway's leading trade partners are Sweden, Denmark, Germany, and the United Kingdom. Norway also trades with other European countries and the United States.

Transportation. Norway's merchant fleet ranks as one of the world's largest. Several hundred vessels link the coastal cities and towns of Norway. Inland, ferries cross many fiords and rivers.

Norway has an extensive road system. Almost all Norwegian households own an automobile. The world's longest highway tunnel, the Lærdal Tunnel, opened in 2000. It extends 15.2 miles (24.5 kilometers) under the Jotunheimen mountain range in southern Norway.

The government owns and operates nearly all the railroads. It also owns part of the Scandinavian Airlines System, which flies throughout the world. Several airlines provide regular service to all parts of Norway. The country's chief airports are located at Oslo, Bergen, Stavanger, and Trondheim.

Communication. Norway has about 80 daily newspapers. The most important dailies include the *Aftenposten, Dagbladet, Dagsavisen,* and *Verdens Gang* of Oslo; the *Bergens Tidende* of Bergen; and the *Adresseavisen* of Trondheim. Many of the country's newspapers support the views of one of the major political parties.

The government-owned Norwegian Broadcasting Corporation operates the national radio and television systems. No advertising is allowed on its programs. The corporation is funded by license fees on all television sets in the country. In 1992, Norway's first nationally broadcast commercial television station, TV2, began operating. Now there are several commercial television stations as well as local commercial radio stations. Norway has an average of 1 radio for every person and 1 television set for every 2 people.

The government owns and operates the telegraph system and most telephone services. Telegraph and telephone lines connect all sections of Norway.

History

Early days. Almost 11,000 years ago, people lived ong the northern and western coasts of what is now orway. Most of the region was covered by thick ice heets, which took thousands of years to melt. By 2000 C., people had started to settle there permanently. By e time of Christ, Germanic tribes had spread through-ut the region, and they continued to arrive for hun-reds of years. These tribes formed local and regional ommunities ruled by chiefs and kings.

The Viking period. Viking sea raiders from the Nor-egian communities spread terror through much of estern Europe for about 300 years. Beginning with reat Britain and Ireland in A.D. 793, they attacked oastal towns and sailed away with slaves and treasure. he Vikings also sailed to the west and established olonies in the Faroe Islands and other North Atlantic is-nds. About 870, they explored farther west and colo-zed Iceland. Eric the Red brought the first group of ettlers to Greenland about 985. About 1000, his son, Leif ricson, led what is believed to have been the first voy-ge of Europeans to the mainland of America. See **Eric e Red; Ericson, Leif; Vikings** (The Norwegian Vikings).

About 900, much of present-day Norway was united nder Norway's first king, Harold I (called Fairhair), or arald I. He defeated many local chieftains and kings, nd others recognized his leadership. King Olav I Trygg-ason began the widespread conversion of Norway to hristianity in the 990's. In the early 1000's, Olav II chieved full Norwegian unity and firmly established hristianity. He became recognized as Norway's patron aint soon after his death in 1030.

The Viking period ended around 1100. The church rew in power, foreign trade expanded, and religious nd trading centers became important cities. Political onfusion and bitter struggles for royal power also de-eloped. Beginning in 1130, many regional leaders laimed the throne. They were defeated in a series of ivil wars that lasted until 1240. Peace was restored un-er Haakon IV. By 1300, Norway's economy was largely ontrolled by north German merchants. Norwegians had ecome dependent on them for grain imports. Norway as weakened further in 1349 and 1350, when about alf of its people died in an epidemic of plague.

Union with Denmark. Margaret, the wife of King aakon VI of Norway, was also the daughter of the king f Denmark. After her father died in 1375, she had her oung son elected king and she ruled Denmark as re-ent. Haakon died in 1380, and Margaret became regent f Norway as well. In 1388, during political confusion in weden, Swedish noblemen elected her to rule that ountry, too. In 1397, in the Union of Kalmar, Margaret nited Norway, Denmark, and Sweden, with power cen-ered in Denmark. Sweden revolted against Danish rule everal times, and broke away from the union in 1523.

Under the Danish-controlled union, Norway grew eaker and Denmark became stronger. In 1536, Den-ark declared Norway a Danish province and made utheranism the official Norwegian religion. Although anish law acknowledged Norway as a separate king-om in 1665, the monarch of Denmark continued to rule orway.

During the 1500's, Norway exported increasing amounts of lumber to the countries of western Europe. As a result, Norway began to develop a great shipping industry during the late 1600's. The industry expanded rapidly throughout the 1700's.

Important dates in Norway

c. 870	Norwegian Vikings colonized Iceland.
c. 900	Harold I united Norway.
c. 985	Eric the Red colonized Greenland.
c. 1000	Leif Ericson sailed to North America.
1349-1350	An epidemic of plague killed about half the people of Norway.
1380	Norway was united with Denmark.
1536	Norway became a Danish province. Lutheranism was made Norway's official religion.
1814	Denmark gave up Norway to Sweden but kept Norway's island colonies.
1884	The cabinet of Norway became responsible to the parliament instead of the king.
1905	Norway became independent.
1940-1945	German troops occupied Norway in World War II.
1945	Norway joined the United Nations.
1949	Norway became a member of the North Atlantic Treaty Organization.
1957	King Haakon VII died and was succeeded by Olav V.
1960	Norway and six other nations formed the European Free Trade Association.
1967	Norway began its greatest welfare program, which combined many established social security plans under the National Insurance Act.
1970's	Norway began producing petroleum and natural gas from North Sea fields, greatly stimulating the economy.
1991	King Olav V died and was succeeded by Harald V.

Union with Sweden. In 1807, during the Napoleonic Wars, Denmark sided with France against the United Kingdom. The United Kingdom had been Norway's chief trading partner, but now the British ended the trade. British warships blockaded Norway's trade with other countries, and many Norwegians starved. Norway was cut off from Denmark by the British blockade and began to manage its own affairs. The Norwegians secretly be-gan to trade with the British again.

Denmark was defeated in 1813 by Sweden, an ally of the United Kingdom against France. In 1814, in the Treaty of Kiel, Denmark gave Norway to Sweden. Den-mark kept Norway's island colonies—Greenland, Ice-land, and the Faroe Islands.

© J. Brun, Mittet Foto

Norwegian Vikings sailed long wooden ships—like this one preserved in an Oslo museum—in raids along the coast of west-ern Europe. They also explored the North Atlantic Ocean.

The National Assembly, Eidsvoll 1814 by Oscar Wergeland.
Storting, Oslo (O. Vaering)

The Constitution of Norway was adopted in 1814 by an elected assembly at Eidsvoll, near Oslo. It has remained in effect since then with only minor changes. This painting of the assembly, presented to the parliament in 1885, hangs in the Storting's main chamber.

The Norwegians did not recognize the Treaty of Kiel. Later in 1814, they elected an assembly to draw up a constitution for an independent Norway. The constitution was adopted on May 17, but Sweden refused to grant Norway independence. Swedish forces attacked Norwegian troops and quickly defeated them. In November 1814, the Norwegian parliament accepted King Charles XIII of Sweden as Norway's ruler as well. Charles promised to respect the Norwegian constitution.

In 1884, after a long political struggle, the parliament won the right to force the cabinet to resign. Until that time the cabinet had been responsible only to the king.

Independence. During the 1890's, Norway's merchant fleet was one of the largest in the world. But the Swedish foreign service handled Norway's shipping affairs in overseas trading centers. Norway demanded its own foreign service, but Sweden refused. In May 1905, the Norwegian parliament passed a law creating a foreign service, but the Swedish king vetoed it. On June 7, the parliament ended the union with Sweden.

Sweden nearly went to war against Norway. However, Sweden recognized Norway's independence in September 1905, after all but 184 Norwegians voted for independence. In November, the people approved a Danish prince as their king. He became Haakon VII.

By the time of independence, Norway had started to develop its many mountain streams to produce hydroelectric power. Its industries expanded rapidly with this cheap power source. Norway's economy increased further during World War I (1914-1918). Norway remained neutral, but its merchant fleet carried much cargo for the Allies. About half its ships were sunk by German submarines and mines.

An economic depression hit Norway following the end of World War I. The nation's economy, dependent on trade and shipping, suffered further during the worldwide depression of the 1930's. Between a fourth and a third of Norway's workers were usually unemployed during this period.

World War II began in 1939, and Norway tried to remain neutral. But on April 9, 1940, Germany invaded Norway by attacking all its main seaports at once. The Norwegians fought bravely for two months, aided by some British, French, and Polish troops. On June 7 of that year, King Haakon VII and the Cabinet fled to London where they formed a government-in-exile. The Germans made Vidkun Quisling, a Norwegian who supported them, premier of Norway. His last name became an international word for *traitor*.

A secret Norwegian resistance army conducted sabotage against the German occupation force. These Norwegians were trained chiefly to join a hoped-for Allied invasion of Norway. Other Norwegians fled their country and trained in Sweden or the United Kingdom for the invasion. Some took part in British commando raids in Norway. After each raid, the Germans shot, tortured, or imprisoned many Norwegians.

Norwegian fighter pilots trained in Canada, and operated from bases in the United Kingdom and Iceland. Norway's merchant fleet carried war supplies for the Allies. The Norwegian navy helped protect Allied shipping, and took part in the invasion of France in 1944.

On May 8, 1945, after Germany fell, the 350,000 German troops in Norway surrendered. Haakon VII returned in triumph on June 7, the 40th anniversary of Norwegian independence. About 10,000 Norwegians died during the war, and about half the merchant fleet was sunk. The far northern counties of Finnmark and Troms lay largely in ruins. See **World War II**.

Postwar developments. After the war, loans from the United States helped Norway rebuild its merchant fleet and industries. By the late 1950's, the Norwegian economy was thriving.

Norway became a charter member of the United Nations in 1945. The next year, Trygve Lie of Norway became the first secretary-general of the UN. In 1949, Norway became a charter member of the North Atlantic Treaty Organization (NATO). But Norway refused to per-

mit NATO bases or nuclear weapons on its territory for fear of angering the Soviet Union, its neighbor on the northeast. (The Soviet Union had been formed under Russia's leadership in 1922, and it existed until 1991). In 1960, Norway and six other countries formed the European Free Trade Association, an economic union (see **European Free Trade Association**).

In 1957, Haakon VII died. His son became King Olav V of Norway.

Social and economic changes. In 1966, the parliament passed the National Insurance Act. The program combined such social security plans as old-age pensions, job retraining, and aid for mothers, orphans, widows, widowers, and disabled people. The Norwegians based much of their expanded social welfare program on the Swedish system, which provided many benefits.

In 1972, Norway signed a preliminary treaty to join the European Community, an economic organization of European nations. The treaty was submitted for voter approval. Supporters argued that membership would benefit the Norwegian economy, while opponents feared that it would threaten Norway's national identity and quality of life. In September 1972, Norway's voters rejected the membership treaty. The Norwegian government then reached a more limited agreement with the European Community to eliminate tariffs on most industrial goods.

Norway began producing petroleum and natural gas from North Sea fields during the early 1970's. The extraction and processing of petroleum and gas greatly stimulated economic growth. Because of its increased petroleum exports, Norway profited from large increases in the price of oil from the mid-1970's to the early 1980's. During this period, the country's economy continued to expand and unemployment remained low, while many other nations struggled with inflation and slow economic growth. However, during the late 1980's, a decline in the international price of petroleum resulted in a slowing of Norway's economic growth.

Political changes. After decades of socialist Labor Party dominance in the Cabinet, Norway entered a period of rapidly shifting coalitions and governments during the 1980's. Since then, coalition governments, usually led by either the Labor Party or the Conservative Party, have ruled the country.

In 1981, Gro Harlem Brundtland became the first woman to serve as Norway's prime minister. Although her first term lasted less than a year, she held the post again from 1986 to 1989 and from 1990 to 1996.

Until 1990, only a king could serve as monarch of Norway. That year, the Storting amended the Constitution to allow women to inherit the throne. Olav V died in 1991. His son, Prince Harald, succeeded him as King Harald V.

Recent developments. In the 1990's, the European Community grew into the European Union (EU), an organization that promotes political and economic cooperation among member states. In 1992, the Storting voted to join the European Economic Area, which provided some of the benefits of EU membership. Many Norwegians urged that the country join the EU. But in November 1994, Norwegians voted against this.

In 1993, Norway fostered peace negotiations between Israel and the Palestine Liberation Organization, which led to the Oslo accords. In 2000, Norway began helping in peace negotiations between Sri Lanka's government and that country's Tamil rebels. Terje I. Leiren

Norwegian elkhound is a hunting dog that originated in Norway, probably between 5000 and 4000 B.C. Hunters claim the elkhound can scent an elk 3 miles (5 kilometers) away. The elkhound stalks its prey quietly and holds it at bay until the hunter arrives. It is also used in hunting bear and game birds. The elkhound's coat is thick and gray with black tips. The dog weighs about 50 pounds (23 kilograms).

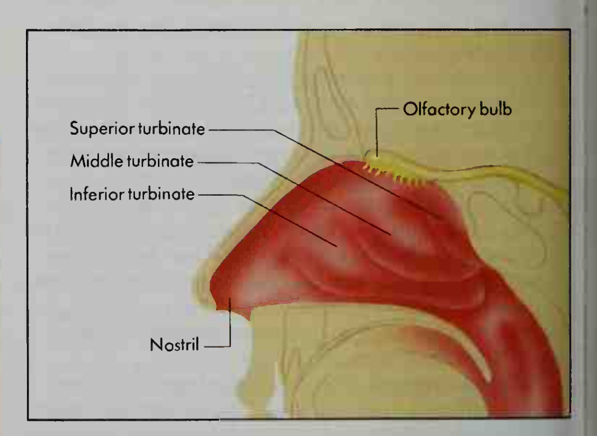
Norwich terrier is a breed of dog that developed in England about 1880. Norwich terriers are alert, quick, sturdy, and instinctively good at hunting mice, rats, and other small animal pests. They make good pets as long as they get plenty of exercise and attention.

Norwich terriers are very similar to Norfolk terriers. But the ears of Norwich terriers stand erect, and those of Norfolk terriers drop forward. The Kennel Club in England recognized the dogs as separate breeds in 1964. The American Kennel Club recognized them as different breeds in 1979. See **Norfolk terrier**.

WORLD BOOK photo by Tom Weigand

The Norwich terrier originated in England.

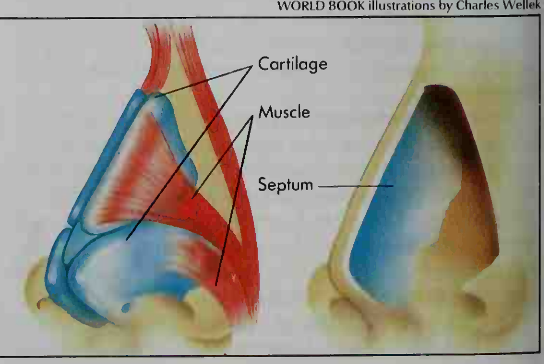
Norwich terriers may be any shade of red, or black and tan. They have a straight, wiry outer coat and a harsh undercoat. The dogs have short, sturdy legs, and sometimes their tail is *docked* (cut) to 3 to 4 inches (8 to 10 centimeters) in length. Full-grown Norwich terriers stand approximately 10 inches (25 centimeters) high at the shoulder and weigh from 10 to 12 pounds (4.5 to 5.4 kilograms).



Critically reviewed by the Norwich and Norfolk Terrier Club

Nose is the organ used for breathing and smelling. It forms part of the face, just above the mouth. Outwardly, it seems simple, but it is complicated inside.

When we breathe, air enters the nose through two openings called *nostrils.* The nostrils are separated by the *septum,* a thin wall of *cartilage* (tough tissue) and bones. Air passes from the nostrils into two tunnels called the *nasal passages,* which lead back to the upper part of the throat. From the nasal passages, air passes through the pharynx and trachea into the lungs.



Both nasal passages have a lining of soft, moist mucous membrane covered with microscopic, hairlike projections called *cilia.* The cilia wave back and forth constantly, moving dust, bacteria, and fluids from the nose to the throat for swallowing. Each nasal passage also has three large, shelflike bones that are called *turbinates* or *conchae.* The top two turbinate bones on each side are actually *processes* (extensions) of the *ethmoid* bone. The lowest turbinate bone on each side is a separate bone. The turbinates warm the air before it enters the lungs. These bones also stir up the air so that dust in the air sticks to the mucous membrane of the turbinates and does not pass into the lungs.

The perception of smell occurs in the highest part of the nasal cavity, where *olfactory nerve receptors* lie in a small piece of mucous membrane about as big as a

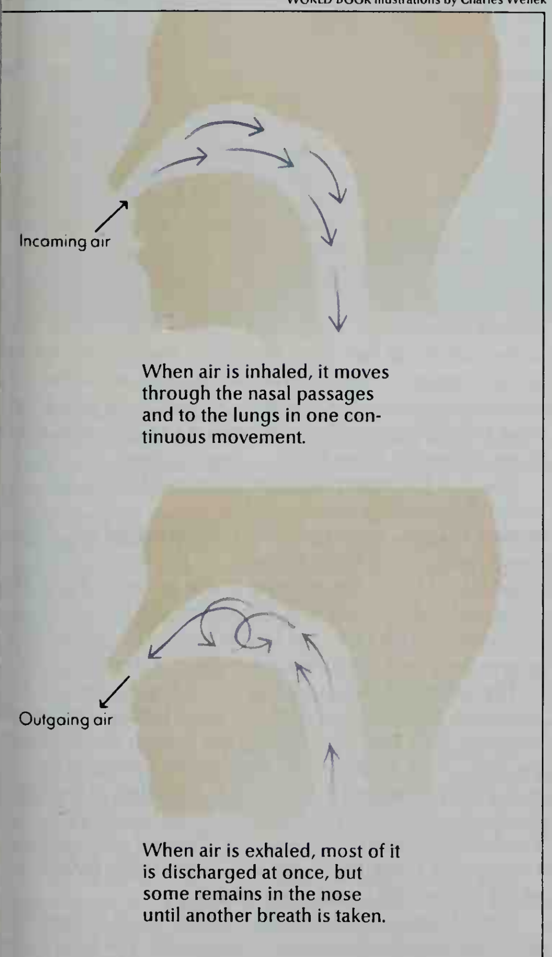
The nose is outwardly simple but inwardly complex. Its interior, *above,* consists of two passages. Each passage contains three shelflike bones called *turbinates,* which are covered by mucous membranes. These bones help warm inhaled air. Nerve fibers extending from an *olfactory bulb* at the top of each passage contain odor-detecting *olfactory nerve receptors.* The exterior of the nose, *below left,* consists largely of an elastic tissue called *cartilage.* So also does the frontmost part of the *septum,* the wall that separates the nasal passages, *below right.*

WORLD BOOK illustrations by Charles Wellek

lime. These receptors generate nerve impulses in response to chemicals in the air. *Olfactory nerve fibers* hen carry the impulses to a part of the brain called the *lfactory bulb.* One olfactory bulb lies just above each asal passage. From there, the impulses are carried to ther parts of the brain, where they are translated into ensations of odor.

The sense of smell is closely related to the sense of aste. Some experts believe that much of our taste sensaions are really sensations of odor that we have associted with certain tastes. For example, we really smell offee, tobacco, wine, apples, and potatoes more than ve taste them. If a person is blindfolded and the nose topped up so that the person cannot smell, the person as great difficulty telling apples from potatoes by taste. Red wine and plain coffee taste almost alike to such a erson when they are at the same temperature and consistency.

We cannot smell when we have a cold, because the nfection inflames the mucous membrane of the nasal assages and blocks the passage of air to the center of mell. It is important to keep nasal passages clean and to reat any inflammation of the mucous membrane at once. When neglected, colds can lead to more serious ailments, such as bronchitis and pneumonia. Sinuses, which empty into the nose, may also become infected.



Charles W. Cummings

How we breathe

WORLD BOOK illustrations by Charles Wellek

When air is inhaled, it moves through the nasal passages and to the lungs in one continuous movement.

When air is exhaled, most of it is discharged at once, but some remains in the nose until another breath is taken.

Nosebleed is a discharge of blood from the nose. Most nosebleeds result from minor irritations of the tissue that lines the lower nasal passages. But nosebleeds may also occur as a symptom of a serious illness or as the result of a head or neck injury. The medical term for nosebleed is *epistaxis.*

The nasal passages are lined with a thin, moist tissue called *mucous membrane.* Many small vessels carry blood close to the membrane's surface. If the membrane becomes dry, even slight knocks or scratches can break the blood vessels. This type of nosebleed commonly occurs in the winter, when nasal tissues become irritated by dry, cool air and by colds and influenza.

WORLD BOOK photos by Dan Miller

To stop minor nosebleeds, lean forward and pinch your nostrils together for about 10 minutes. If bleeding cannot be controlled, seek medical attention.

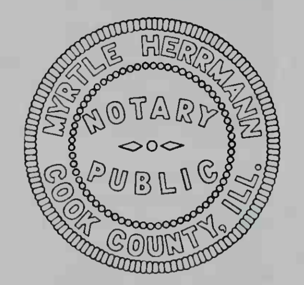
Minor nosebleeds frequently result from irritations of the mucous membrane that covers the *nasal septum,* the structure that separates the two nostrils. Some people have a *deviated septum,* which curves into one of the two nostril chambers. A deviated septum lies directly in the path of air entering the nose, and therefore is likely to become dried and to bleed if irritated.

To stop a minor nosebleed, sit down and lean forward, with your chin toward your chest. Then, pinch your nostrils together for about 10 minutes, or until the bleeding stops. If the nosebleed does not stop after using these measures, seek medical attention.

Severe nosebleeds may be a symptom of a blood-clotting disorder, leukemia, or the rupture of a large blood vessel at the back of the nose. Heavy bleeding from the nose may be life-threatening and thus requires emergency medical care. If a head or neck injury is suspected, do not move the person. Prevent the head and neck from moving by stabilizing them with your hands. Have someone call for an ambulance immediately.

David D. Caldarelli Critically reviewed by the American Red Cross

Nostradamus, *NAHS truh DAY muhs* (1503-1566), was the Latin name of Michel de Notredame, a French astrologer and physician. His fame rests on his book *Centuries* (1555), a series of prophecies in verse. Nostradamus won lasting fame in 1559 when King Henry II of France died in a manner predicted in the *Centuries.*



Bettmann Archive
Nostradamus

Nostradamus was born in St.-Rémy, in southern France. He earned a doctor's degree in 1532, and became a professor at the University of Montpellier. The success of *Centuries* gained him an appointment as court physician to King Charles IX of France. He also became an adviser to Catherine de Médicis, wife of King Henry II of France.

Nostradamus' prophecies are vague and open to interpretation. One published in 1921 seemed to predict World War II (1939-1945). During that war, the Nazis issued their own versions of Nostradamus's prophecies to convince the German people and their European enemies of the Nazis' ultimate victory. John Bell Henneman

Nostril. See Nose.

Notary public, *NOH tuhr ee,* is an officer authorized by state law to certify certain documents and to take oaths. Many documents, such as deeds, must be notarized before they become legally effective. The purpose of notarizing a document is to protect those who use it from forgeries. The notary signs the document to certify that the individual who signed it appeared in person and swore to the notary that the signature on the document is genuine. The notary records that fact, then stamps a seal on the document.

The notary public seal is pressed into paper with a small hand stamp.

In many states, any responsible person can get a commission as a notary public, on payment of a fee. Notaries are usually allowed to charge for their services. In Great Britain and Canada, the Court of Faculties appoints notaries. Jack M. Kress

Notation, *noh TAY shuhn,* is any system of symbols and abbreviations that helps people work with a particular subject. Mathematics uses notation to simplify and consolidate ideas and problems. The Arabic numeral system is a notational device for writing numbers and making arithmetic easier. Chemistry, music, physics, and other subjects have also developed notation systems.
See also **Arabic numerals; Numeration systems; Music** (Musical notation); **Symbol.** Howard W. Eves

Note is an unconditional written promise to pay a specified sum of money on demand or at a given date to a designated person. The one who signs the note is called the *maker.* The one to whom it is made payable is called the *payee.* This written promise is called a *promissory note. Note of hand* is a name sometimes used for a promissory note.

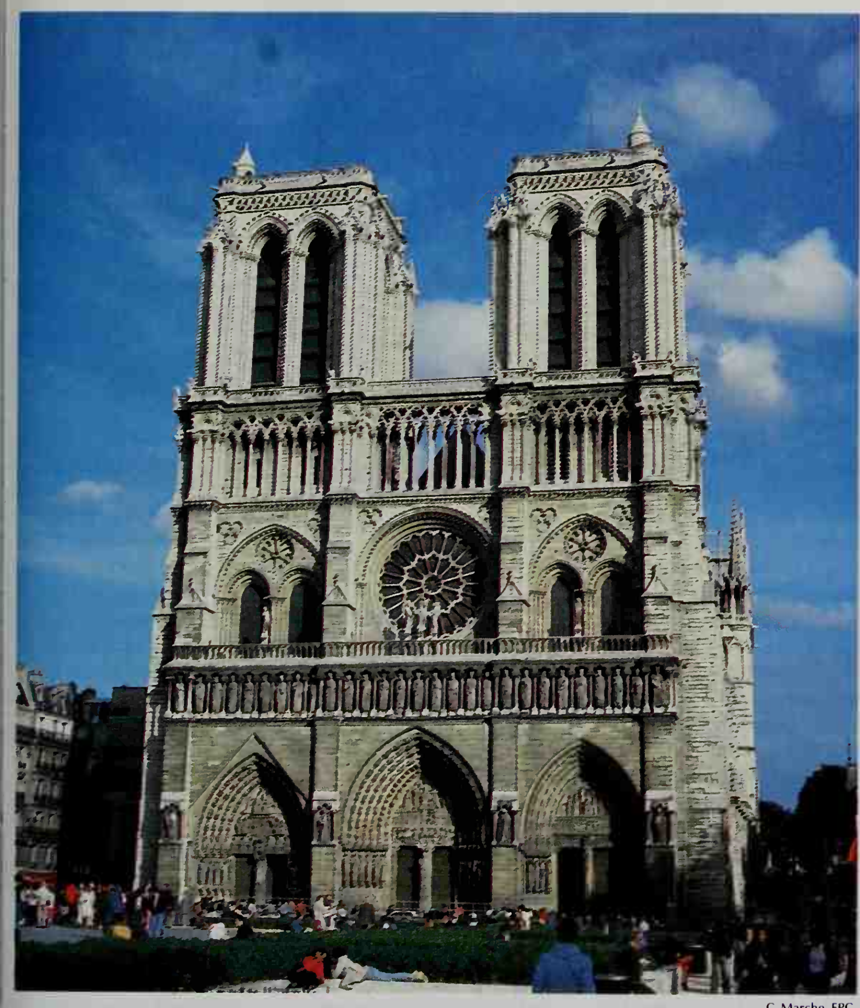
Suppose that Arlene Shaw, a retail merchant with a good business and a good financial standing, needs $500 worth of merchandise but does not have the cash to pay for it. She knows that she has accounts coming due within 60 days. She will be able to pay the $500 when she is paid by those who owe her. She goes to Henry Brown, a wholesale merchant, who sells her the goods and takes her note. The note is as follows:

> $500 San Francisco, Calif.
> March 1, 1991
> Sixty days after date I promise to pay to the order of Henry Brown $500, with interest at 10 per cent. Value received.
> Arlene Shaw

Brown can endorse the note and cash it at the bank, if he needs the money before 60 days. Shaw will then pay the bank when her note becomes due. Sometimes the maker specifies the actual date of payment in the note.

Liability of the maker. A note is *negotiable* when it is made payable to "bearer" or includes the word "order," like the one given above. When a note has been transferred by endorsement, the person in possession of the note is known as the *holder.* The holder can transfer it to another by endorsing it, and so on indefinitely, just as a bank check can be transferred. When the note falls due, the holder looks to the maker for payment. The law protects the holder under almost all conditions, including some kinds of fraud or cheating by the payee.

An endorser is liable in case the maker fails to pay the note when it falls due. The endorser is served with a notice called a *protest.* It is signed by a notary public, and one copy is sent to each endorser if there is more than one (see **Notary public**).



Caution. No one should sign a document without fully understanding what is being signed. A lawyer should examine any document that the maker does not understand. The law holds the maker responsible for his or her signature, except when any part, or all, of the document is proved fraudulent in court, or is proved to have been altered without the maker's knowledge, after it was signed in good faith. Joanna H. Frodin

Notre Dame, *NOH truh DAHM,* **Cathedral of,** is a famous cathedral in Paris. It stands on the Île de la Cité, a small island in the Seine River, in the center of Paris. The cathedral is dedicated to *Notre Dame,* the French expression for *Our Lady,* the Virgin Mary. The cathedral is one of the finest examples of Gothic architecture.

The cathedral stands on the site of two earlier churches. Construction of the present building occurred between 1163 and 1250. During the French Revolution in the late 1700's, Notre Dame was heavily damaged by mobs who regarded the church as a symbol of the hated monarchy. Beginning in 1845, the French architect Eugène Emmanuel Viollet-le-Duc directed extensive restorations of Notre Dame. He was responsible for much of the cathedral's present appearance.

Notre Dame was one of the first buildings to have *flying buttresses* (arched exterior supports). The buttresses strengthen the walls and permit the use of large stained-

G. Marche, FPG

The Cathedral of Notre Dame is a masterpiece of Gothic architecture and one of the most famous buildings in Europe. It stands on a small island in the Seine River in the heart of Paris. The cathedral was built between 1163 and 1250. This picture shows the main entrance.

glass windows that allow light to enter the building. The cathedral's main entrances are elaborately decorated with stone sculptures. A number of other cathedrals are also named Notre Dame, including those in Amiens, Chartres, and Reims, France. William J. Hennessey

Notre Dame, *NOH tuhr DAYM,* **University of,** is a coeducational Roman Catholic school in Notre Dame, near South Bend, Ind. It is governed by a board of trustees consisting of 35 lay people, and 7 priests of the Congregation of Holy Cross—the order that founded the university. Students of all faiths may attend Notre Dame.

The campus. Notre Dame has a 1,250-acre (506-hectare) campus, with twin lakes and wooded areas that provide a beautiful setting for more than 90 buildings. Landmarks include the Log Chapel, which is a replica of the first building erected at Notre Dame; and the Grotto of Our Lady of Lourdes, which is a replica of a shrine at Lourdes, France.

The 14-story Memorial Library, completed in 1963, has a capacity of about 2 million volumes. Nearly a third of the university's undergraduates can study there at one time. The library's important collections include the Dante Library of books from the early 1500's; the Hiberniana collection of Irish history and literature; the Kirsch-Wenninger-Niewland Biology Library; and the Zahm South American Library.

Bordering the campus is Notre Dame Stadium, where the "Fighting Irish" football team plays. Great football figures, such as coach Knute Rockne, George Gipp, and the Four Horsemen of Notre Dame, brought the university much fame (see **Rockne, Knute**).

Educational program. Notre Dame's undergraduate school has colleges of arts and letters, business administration, engineering, and science. Courses in these colleges lead to bachelor's degrees. The College of Business Administration also grants the master's degree. Notre Dame's law school, the first law school at a Roman Catholic university in the United States, offers the Doctor of Laws degree. The graduate school at Notre Dame offers advanced degrees in 30 departments.

The university has awarded the Laetare Medal each year since 1883. The award honors a leading Roman Catholic of the United States for his or her contributions to society.

Research program. Notre Dame places a strong emphasis on research. It receives more than $20 million in

The library at Notre Dame is the tallest building on campus and one of the largest university library buildings in the world. The 14-story building, built at a cost of $12 million, seats 2,900. The exterior features a mural, 132 feet (40 meters) high, made of 7,000 granite pieces. The mural depicts Christ, the apostles, and various scholars.

University of Notre Dame

grants annually for research. The Center for Gerontological Education, Research, and Services investigates the aging process in human beings. The university also conducts research in radiation chemistry at a radiation laboratory built by the U.S. Atomic Energy Commission.

The Medieval Institute conducts research in the culture, life, and thought of the Middle Ages. Other research centers include the Institute for International Peace Studies and the Center for Bioengineering and Pollution Control. The university conducts research in a variety of other areas, including microelectronics materials science and the economics of developing countries. Notre Dame was founded in 1842.

Nottingham, *NAHT ihng uhm* or *NAHT ihng HAM,* is an industrial city in central England. It is the chief city and administrative center of the county of Nottinghamshire. Nottingham lies on the north bank of the River Trent (see **England** [political map]). The district of Nottingham, which includes the city and some surrounding areas, has a population of 279,400.

An old castle towers above the center of Nottingham. Other major landmarks include the University of Nottingham and St. Mary's Church, which is a good example of English church architecture of the 1400's. Sherwood Forest, near Nottingham, was supposedly the home of the legendary English outlaw Robin Hood (see **Robin Hood**).

Nottingham existed by the 800's and became a major center of the wool trade during the Middle Ages. During the late 1700's and early 1800's, the city prospered and its population increased rapidly as a result of the development of hosiery, knitting, and lacemaking industries there. Factories built during the late 1800's and early 1900's manufacture such products as bicycles, cigarettes, and pharmaceutical goods. G. Malcolm Lewis

Nouakchott, *nwahk SHAHT* (pop. 350,000), is the capital and largest city of Mauritania. It lies in western Mauritania, along the Atlantic Ocean. For location, see **Mauritania** (map).

Government buildings and foreign embassies dominate the center of the city. Nouakchott is overcrowded. Severe droughts during the 1970's and 1980's forced large numbers of rural people to move to the city to obtain food and work. Many of them live in shacks and tents. Nouakchott has some modern housing. Its products include hand-woven woolen carpets and other handicrafts, soft drinks, and chemical products.

Nouakchott was founded in 1957, when France ruled Mauritania. It was established to replace St.-Louis, Senegal, as the seat of Mauritania's colonial administration. It became the capital when Mauritania gained independence from France in 1960. Clement Henry Moore

Noun is a part of speech that identifies people, places, objects, actions, qualities, and ideas. The English language has a great variety of nouns. These nouns have been grouped into several classifications, some of which overlap.

Mass nouns and count nouns. Mass nouns identify things that cannot be divided into separate units, such as *fruit* and *soil.* Count nouns identify things that can be divided into units, such as *apple* and *rose.*

Mass nouns and count nouns do not differ completely because some words may belong to either group. In the sentence *I bought cheese,* for example, *cheese* is a mass noun. But in the sentence *I bought the cheeses, cheese* is a count noun. Count nouns, but not mass nouns, occur in the plural and with articles *(a, an, the).* When what is ordinarily a mass noun is used as a count noun, it generally refers to a specific type, as in specific types of cheese.

Abstract and concrete nouns. Abstract nouns identify ideas and qualities that have no physical existence. *Bravery, effort,* and *knowledge* are abstract nouns. In contrast, concrete nouns identify objects that can be seen, heard, smelled, touched, or tasted. *Airplane, layer cake,* and *skyscraper* are concrete nouns. Some words can be used as either abstract or concrete nouns. *Red* as an abstract noun may specify the quality of redness. As a concrete noun, it may represent the color.

Abstract nouns usually function as mass nouns do.

We do not say *She had two knowledges* or *She had the knowledge.* However, when a specific type of knowledge is discussed, it may be treated as a count noun, as in *She has a good knowledge of atomic physics* or *She has the knowledge not to act badly.*

Proper and common nouns. Proper nouns identify particular names or titles and are always capitalized. Examples include *Apollo 11, Beacon Street, Cherokee Park, New Year's Eve,* and *President Lincoln.* Proper nouns are generally used without articles, but there are exceptions, such as *the United States* or names of rivers, such as *the Mississippi River.*

All nouns that are not proper nouns are common nouns. They identify general categories of things, such as *experiment, helper, holiday,* and *river.*

Collective nouns identify groups of persons, animals, or things. Examples include *audience, class, crowd, family, flock, government,* and *team.* A collective noun may be considered singular if the word is used as a unit. In this instance, the noun takes a singular verb. For example, *The cast of the play* was *at its best.* A collective noun is considered plural if the word is used in terms of its parts. The noun then takes a plural verb—*The cast* were applauded *loudly for their performances.*

Nominals are words and phrases that function as nouns. Pronouns are the most common nominals, but other parts of speech may be used as nouns:

Adjective: *The* strongest *was not best.*
Gerund: *Clam* digging *is fun.*
Infinitive: To err *is human.*
Prepositions: *We knew the* ins *and* outs.
Pronoun: He *took a walk.*

Number and case. English nouns may have endings that show *number* and *case.*

Number is the form which indicates that the noun refers to one (singular) or to more than one (plural). Singular nouns indicate one, such as *pear, apple, man,* and *mouse.* Plural forms for these nouns are *pears, apples, men,* and *mice.* Abstract nouns, mass nouns, and proper nouns do not ordinarily have distinct plural forms. In special cases, these may be used as count nouns and take plurals, as in *There are three* Sams *in this room.*

Case is the form that helps show the relation of a noun to other words in a sentence. In some languages, words have many different endings to show relationships. In English, word order, rather than endings, shows relationships. Modern English nouns have only two cases, *common case* and *possessive case. Boys, man,* and *Sam* are common-case forms. *Boys', man's,* and *Sam's* are possessive-case forms.

Gender. In English, nouns are sometimes said to have gender, but this is not regularly shown by endings. An English noun has gender only in the sense that it is referred to by one of three sets of pronouns: *he* or *him, she* or *her,* or *it.* For example, *I found Jim and brought* him *home; I found Sally and brought* her *home;* and *I found a book and brought* it *home.*

Nouns for which the corresponding pronoun is *he* or *him* are *masculine* nouns. Nouns for which the corresponding pronoun is *she* or *her* are *feminine* nouns. Nouns for which the corresponding pronoun is *it* are *neuter* nouns. Usually, masculine nouns name males, feminine nouns name females, and neuter nouns name inanimate or sexless things. However, there are some exceptions. Some people refer to ships as *she,* though most authorities prefer *it.* Babies are often referred to as *it,* except where the sex is known. Even when the sex is known, *it* is more common for many animals. In many languages, the relationship between gender and natural sex is not as close as it is in English. For example, learners of German must memorize noun genders.

There is a tendency in modern English to stop using special words for women. Some pairs are still common, such as *actor* and *actress,* but words like *aviatrix* for a female aviator are virtually obsolete. Susan M. Gass

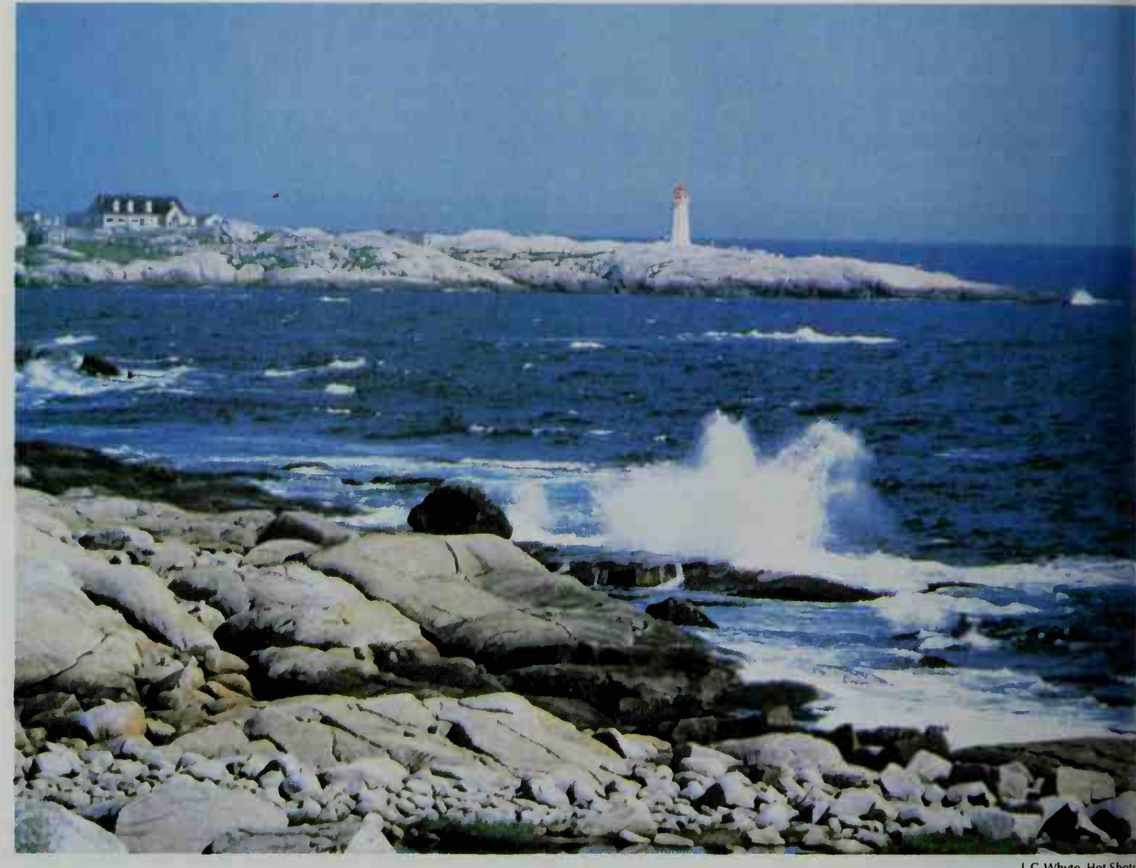
Nova is an explosion that causes a star to become from 10,000 to 100,000 times as bright as the sun. The star may shine this brightly for a month or longer before gradually fading to its original brightness. A nova hurls huge masses of gas and dust into space. The word *nova* comes from the Latin word for *new.* People once mistook novae for new stars.

Stars that undergo *fast novae* reach their maximum brightness several hours after the explosion. They begin to fade after a few days. Stars that undergo *slow novae* take much longer to reach their maximum brightness. However, they stay extremely bright for months or even years before they fade to their original brightness. Fast novae propel gas and dust outward at speeds of a few thousand miles or kilometers per second. Slow novae do so about a tenth as fast.



Astronomers believe that novae occur in *close binaries.* A close binary is a double star system in which two stars revolve closely around each other (see **Binary star**). For a nova to occur, one of the stars must be medium-sized, and the other must be a small, extremely dense star called a *white dwarf.* The two stars are so close that the gravitational pull of the white dwarf draws material rich in hydrogen from the larger star. This material collects on the white dwarf and eventually triggers reactions of *nuclear fusion* there. In such reactions, hydrogen nuclei combine to form helium nuclei, and a large amount of energy is released. The reactions quickly become a runaway process, which results in a nova.

During the last 100 years, astronomers have observed some stars that have undergone more than one nova. Astronomers call such explosions *recurrent novae.* All novae may be recurrent, but for some of them the interval between explosions may be hundreds or even thousands of years. This much time may be required for a white dwarf to accumulate enough hydrogen for nuclear fusion to recur. On the other hand, the causes of recurrent and ordinary novae may differ, and ordinary novae may occur only once in a close binary.

Some close binaries undergo small explosions every month or so. These *dwarf novae* do not throw out material during an outburst, and they become only 10 to 100 times as bright as the sun. Their cause is unknown. Other stars undergo explosions called *supernovae,* which are thousands of times as bright as ordinary novae. Some supernovae occur in binaries, while others result from the collapse of extremely massive stars.

Sumner Starrfield

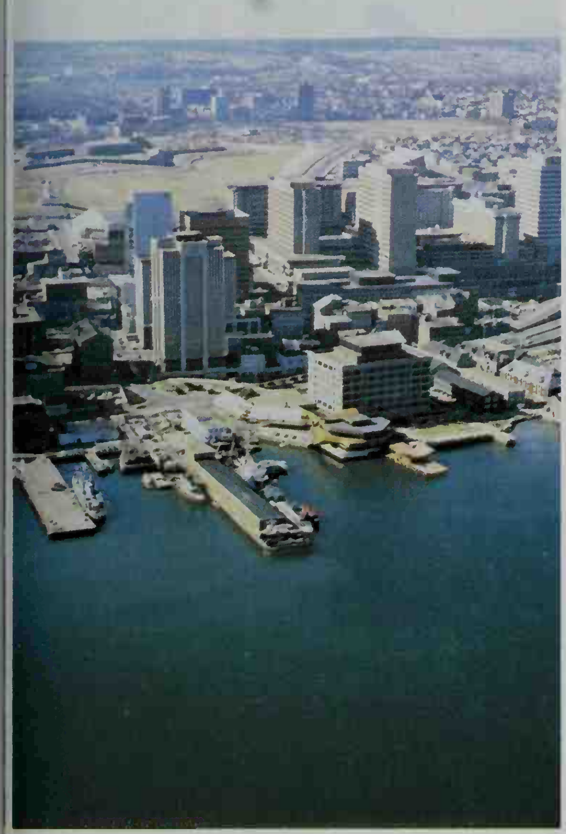
The scenic rocky coast of Nova Scotia

Nova Scotia

Nova Scotia, *NOH vuh SKOH shuh,* is one of the four Atlantic Provinces of Canada. It includes a peninsula of the Canadian mainland and also Cape Breton Island. The province juts out into the Atlantic Ocean from the Canadian mainland. Each year, many visitors enjoy Nova Scotia's beaches and coastal resorts.

No part of Nova Scotia is more than 35 miles (56 kilometers) from the sea. The Atlantic Ocean, the Gulf of St. Lawrence, and the Bay of Fundy almost surround the province. Only a narrow strip of land—the Isthmus of Chignecto—joins the peninsula to the Canadian mainland. Ocean tides may rise higher in Nova Scotia than anywhere else in the world. Sometimes the tide rises more than 50 feet (15 meters) at the head of the Bay of Fundy. Sable Island, which is formed entirely of sand, lies about 100 miles (160 kilometers) offshore toward the southeast. Sailors call Sable Island the *Graveyard of the Atlantic* because it has been the scene of many shipwrecks.



The contributors of this article are Hugh Millward, Professor of Geography at St. Mary's University, and D. A. Sutherland, Associate Professor of History at Dalhousie University.

The sea keeps the climate of Nova Scotia from becoming either extremely hot or extremely cold. Thick forests cover much of the province. In the north, ranges of low hills stretch across parts of Nova Scotia. Seawater reaches far inland in many rivers that irrigate the rich soil of lowland farms. The Annapolis Valley, famous for its apple orchards, glows with pink and white apple blossoms in spring.

White-tailed deer roam the wilderness areas. Many kinds of sea birds nest along the shore and on offshore islands. Lobsters, scallops, and other seafood caught off Nova Scotia help make the province one of the leaders in the Canadian fishing industry.

Service industries are the leading economic activity in Nova Scotia. These industries include education, government, and hotels and restaurants. Manufacturing is also important to the province's economy. The leading products include food products, paper products, transportation equipment, and printed materials. Nova Scotia leads the provinces in mining gypsum.

People have lived in the Nova Scotia region for about 10,000 years. A series of Native American cultures existed in the region before European explorers arrived in the early 1500's. French settlement began at Port Royal

Halifax, an important Canadian port

Interesting facts about Nova Scotia

WORLD BOOK illustrations by Kevin Chadwick

First airplane flight

The first airplane flight in Canada was made on Feb. 23, 1909, over Bras d'Or Lake near Baddeck Bay. J. A. D. McCurdy flew the Silver Dart, which was designed and built by the Aerial Experiment Association under Alexander Graham Bell. It flew 10 to 30 feet (3 to 9 meters) off the ground at a speed of 40 miles (65 kilometers) per hour for a distance of half a mile (0.8 kilometer). The flight was the first by a British subject in the British Empire.

Steamship mail service

The first regular mail service by steamship between Britain, Canada, and the United States was established by Sir Samuel Cunard of Halifax. The paddle steamer *Britannia* began the mail service by crossing from Liverpool to Halifax to Boston in 14 days 8 hours in July 1840.

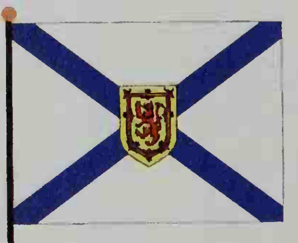
The first newspaper in Canada was the *Halifax Gazette.* John Bushnell published the first issue on March 23, 1752.

in 1605. British settlers first came to Nova Scotia in 1629. Britain won control of Nova Scotia in the mid-1700's. The Latin words *Nova Scotia* mean *New Scotland.*

The American poet Henry Wadsworth Longfellow made Nova Scotia famous in his poem *Evangeline.* This partly fictional poem tells how French colonists, called Acadians, were driven from their homes in Nova Scotia by British troops. The poem gave part of the province the nickname *Land of Evangeline.*

In the early 1750's, settlers from Britain and other parts of Western Europe began coming to Nova Scotia in increasing numbers. During and after the Revolutionary War in America (1775-1783), many people who remained loyal to Britain fled from the United States to Nova Scotia. By the 1820's, people had begun to refer to Nova Scotians as "bluenosers," a nickname that probably came from locally-grown blue potatoes. Today, Nova Scotians still call themselves "Bluenosers."

Nova Scotia, along with New Brunswick, Ontario, and Quebec, was one of the four original Canadian provinces. These four formed the Dominion of Canada in 1867. For the relationship of Nova Scotia to other provinces, see **Atlantic Provinces; Canada; Canada, Government of; Canada, History of.**



Sherman Hines, Masterfile

Apple blossoms in the Annapolis Valley

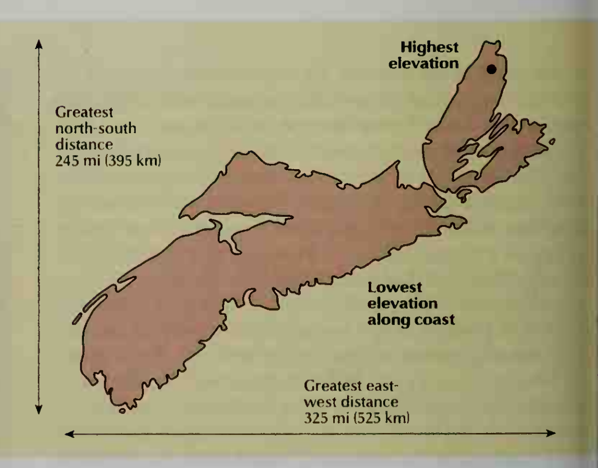
Nova Scotia in brief

Symbols of Nova Scotia

The provincial flag, first authorized by a royal grant in 1625, bears the cross of St. Andrew and the arms of Scotland. These symbols show the province's historical ties to Scotland. The provincial coat of arms, also granted in 1625, has the same symbols on a shield in the center. The Indian represents the province's original inhabitants. A royal unicorn symbolizes England.

Provincial flag

Nova Scotia (brown) ranks ninth in size among all the provinces and third among the Atlantic Provinces (yellow).



Province House is in Halifax, the capital of Nova Scotia since 1749. Annapolis Royal served as the region's capital from 1710 to 1749.

General information

Entered the Dominion: July 1, 1867; one of the original four provinces.
Provincial abbreviation: NS (postal).
Provincial motto: *Munit Haec et Altera Vincit* (One Defends and the Other Conquers).

Land and climate

Area: 21,423 mi² (55,490 km²), including 1,023 mi² (2,650 km²) of inland water.
Elevation: *Highest*—1,747 ft (532 m) above sea level in Cape Breton Highlands National Park. *Lowest*—sea level.
Coastline: 4,709 mi (7,579 km).
Record high temperature: 101 °F (38 °C) at Collegeville, near Antigonish, on Aug. 19, 1935.
Record low temperature: −42 °F (−41 °C) at Upper Stewiacke on Jan. 31, 1920.
Average July temperature: 64 °F (18 °C).
Average January temperature: 23 °F (−5 °C).
Average yearly precipitation: 53 in (134 cm).

Important dates

1497-1524 European explorers reached Nova Scotia while seeking a sea route to Asia.

1605 Samuel de Champlain and Pierre du Gua, Sieur de Monts, founded Port Royal.

1713 France gave Britain territory, including all of Nova Scotia except Cape Breton Island, under the Peace of Utrecht.

1755 British colonial troops from New England began to drive French Acadians out of Nova Scotia.

Government

Provincial government

Premier: term of up to 5 years
Members of the Legislative Assembly: 52; terms of up to 5 years

Federal government

Members of the House of Commons: 11
Members of the Senate: 9

Sources of information

For information on tourism in Nova Scotia, write to: Nova Scotia Tourism and Culture, P.O. Box 456, Halifax, NS B3J 2R5. The Web site at www.novascotia.com also provides tourism information. For information on the economy of Nova Scotia, write to: Economic Development, P.O. Box 519, Halifax, NS B3J 2R7. For information on the government and history of the province, write to: Public Inquiries, P. O. Box 2734, Halifax, NS B3J 3P7. A Web site maintained by the Nova Scotia government at www.gov.ns.ca/about.htm provides a gateway to much useful information about the province's economy, government, and history.

1763 Under the Peace of Paris, France officially gave Cape Breton Island to Britain.

1867 Nova Scotia joined with New Brunswick, Ontario, and Quebec in forming the Dominion of Canada.

1955 The Canso Causeway was opened, linking the Nova Scotia mainland with Cape Breton Island.

1996 Halifax, Dartmouth, Bedford, and the rest of Halifax County were combined to form the Halifax Regional Municipality.

People

Population. The 2001 Canadian census reported that Nova Scotia had 908,007 people. The province's population had decreased by less than one percent since the 1996 census, which reported a total of 909,282.

Most Nova Scotians belong to families that originally came from Scotland, other parts of the United Kingdom, or Ireland. Significant numbers of others are of French, German, African, and Micmac ancestry. A few people in Cape Breton still speak the Gaelic language of their Scottish ancestors. Each year, St. Ann's and some other communities hold Scottish celebrations. These gatherings feature Scottish athletic competitions known as Highland Games, colorful costumes, and singing and dancing to bagpipe music. Other festivities are held regularly to celebrate the cultures of Nova Scotia's French, German, black, and Micmac minorities.

Halifax is the capital of Nova Scotia and by far the largest of the province's three regional municipalities. It includes the communities of Halifax, Dartmouth, and Bedford and the surrounding area. Halifax is one of the most important ports in Canada, as well as being the chief railway and air terminal in Nova Scotia. The Halifax Regional Municipality includes the population center of the province's only Census Metropolitan Area as defined by Statistics Canada.

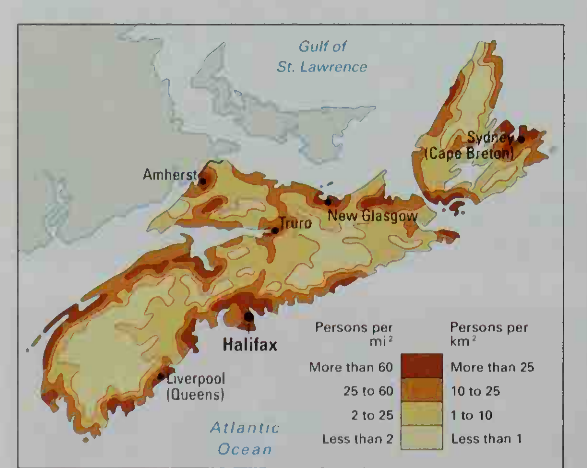
Nova Scotia's second largest regional municipality is the Cape Breton Regional Municipality. It is located on Cape Breton Island and includes the communities of Sydney and Glace Bay. Nova Scotia's towns have populations of less than 25,000. See the separate articles on the communities of Nova Scotia listed in the *Related articles* at the end of this article.

Schools. Public schools in Nova Scotia operate under the provincial Education Act. Nova Scotia's first Education Act was passed in 1766.

The provincial Department of Education supervises the school system. Schools are controlled by locally elected school boards. Each board may include one appointed member of Micmac descent. School boards do not have taxing powers. Funding from the provincial government and from municipalities provides income for the schools. Provincial law requires children to attend school from age 5 to 16. Alternatives to public education include private schools and home schooling, which are both subject to provincial standards.

Libraries. Nova Scotia has nine regional library systems. Regional libraries are funded primarily by the provincial government and municipal councils. Nova Scotia also has a number of college and university libraries.

Museums. The Citadel in Halifax and Fortress of Louisbourg in Louisbourg feature examples of colonial architecture. Both of these national historic sites also present reenactments of life in garrison towns of the past. Grand Pré National Historic Site near Wolfville commemorates Acadian history. Sherbrooke Village in Sherbrooke is a restored town of the 1800's. The Maritime Museum of the Atlantic in Halifax has exhibits on the famous steamer *Titanic.* Other notable attractions include Alexander Graham Bell National Historic Site in Baddeck; Fort Anne and Port Royal national historic sites, both in Annapolis Royal; Nova Scotia Museum of Natural History in Halifax; and the Fisheries Museum of the Atlantic in Lunenburg.



Universities and colleges

Nova Scotia has 10 degree-granting universities and colleges that are members of the Association of Universities and Colleges of Canada.

Name	Mailing address
Acadia University	Wolfville
Cape Breton, University College of	Sydney

Population density

Most of Nova Scotia's people live near the coast. Most of the interior is uninhabited or thinly settled. Halifax is the province's capital and largest regional municipality.

Visitor's guide

Nova Scotia's beaches and shoreline resorts attract many visitors. Fishing enthusiasts can catch striped bass, cod, haddock, and tuna along the coast, and salmon, shad, and trout in the streams. Visitors can also enjoy such sports as canoeing, sailboating, and sea kayaking. The province also has many parks and campgrounds. Halifax, the capital of Nova Scotia and one of the most historic places in Canada, has a number of historic buildings. See **Halifax**.

Many visitors attend the Gaelic festival in St. Anns. They enjoy listening to the sound of bagpipe music and watching the Scottish sport of tossing the caber. In this event, contestants throw the *caber* (a heavy wooden pole) end over end as far as they can. Winter sports in Nova Scotia include curling, hockey, skating, and skiing.

Nova Scotians enjoy festivities celebrating the many aspects of their heritage. The Highland Games, a well-known Scottish festival, takes place in Antigonish in July.

Places to visit

Following are brief descriptions of some of Nova Scotia's many interesting places to visit:

***Bluenose II*,** based in Lunenburg, is a replica of *Bluenose*, a Canadian schooner that won the International Fisherman's Trophy in 1921, 1922, 1923, 1931, and 1938. Visitors may tour *Bluenose II* when it is in port and may take cruises in June, July, August, and September.

Cabot Trail offers motorists a magnificent view of the sea. This highway winds through the wilderness areas of northern Cape Breton Island.

Ceilidh Trail follows the northwest shore of Cape Breton. It offers a view of saltwater bluffs, beaches, and hills and valleys.

Evangeline Trail winds through fishing villages and rolling farmland in the Annapolis Valley of Nova Scotia.

Glooscap Trail offers glimpses of the world-famous fossil cliffs at Joggins and the spectacular tidal bore, caused by the highest tides in the world.

The Lighthouse Route, between Yarmouth and Halifax, passes fishing villages and famous shipbuilding towns.

Marine Drive extends for 250 miles (400 kilometers) along the eastern shore of Nova Scotia's Atlantic coast.

National parklands. Nova Scotia has two national parks—Cape Breton Highlands National Park, on Cape Breton Island, and Kejimkujik National Park, in southwestern Nova Scotia. Canada's government also operates nine national historic parks and sites, including the Citadel and York Redoubt, in Halifax, and Fortress of Louisbourg National Historic Park, in Louisbourg. Alexander Graham Bell National Historic Park, in Baddeck, displays inventions, models, notes, and photographs of Alexander Graham Bell, inventor of the telephone. See Canada (National Park System).

Provincial parks. Nova Scotia has about 120 provincial parks. For information on them, write to Department of Natural Resources, Parks and Recreation Division, RR 1, Belmont, NS B0M 1C0. The department's Web site at www.gov.ns.ca/natr also provides information on Nova Scotia's provincial parks.

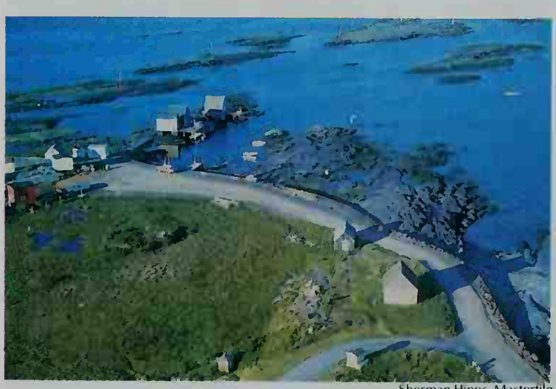
Land and climate

Land regions. Nova Scotia has three main land regions. They are (1) the Atlantic Plateau, (2) the Northern Highlands, and (3) the Lowlands.

The Atlantic Plateau rises gradually from sea level on the Atlantic coast to about 700 feet (220 meters) inland. Hard rocks from 400 million to 500 million years old generally lie beneath the surface of the region. These rocks were worn down to sea level to form a plain. About 70 million years ago, the plain uplifted slightly and tilted so that it sloped to the southeast. In the last ice age, which ended about 11,500 years ago, glaciers removed most of the topsoil, exposing bedrock in many places. The action of glaciers also created many lakes and bogs. Today, the Atlantic Plateau is covered with forests, and the land is unsuitable for farming.

The Northern Highlands consist of masses of harder rocks that are generally over 400 million years old. These rocks form the rugged slopes of the Cobequid Mountains, the Pictou-Antigonish Highlands, and the Cape Breton Highlands. The highest point in Nova Scotia rises to 1,747 feet (532 meters) above sea level in Cape Breton Highlands National Park.



The Lowlands lie mainly in central and northern Nova Scotia. Soft rocks about 200 million to 350 million years old lie beneath the surface of the region. They have worn down more rapidly than the harder rocks in the hills and plateaus of Nova Scotia's other regions.

The Lowlands are gently rolling plains. They have Nova Scotia's finest soils and mineral deposits. The rich farmland of the Annapolis Valley is south of North Mountain, which rises along the Bay of Fundy. Fertile marshlands lie at the head of the Bay of Fundy, along the inlets called Chignecto Bay and Minas Basin. These marshlands also extend far inland along many rivers. Beneath the Lowlands are rich deposits of coal and gypsum. There are also deposits of limestone, quartz, rock salt, sandstone, and shale.

Coastline of Nova Scotia measures 4,709 miles (7,579 kilometers). This includes 2,517 miles (4,051 kilometers) of mainland, 1,170 miles (1,883 kilometers) of major islands and 1,022 miles (1,645 kilometers) of minor islands. The rocky southern shore has many inlets. Fishing fleets use the large inlets as harbors. Small islands lie off the southern coast.

Rivers and lakes. Nova Scotia's rivers are all narrow, and few are over 50 miles (80 kilometers) long. The Mersey and the St. Mary's rivers, both 72 miles (116 kilometers) long, are the longest in the province. The Mersey rises on South Mountain and flows through several lakes, including Lake Rossignol. Rich farmland lies along the Annapolis and Shubenacadie rivers, which flow into the Bay of Fundy. Other important rivers include the La Have and Musquodoboit, which flow into the Atlantic, and the Margaree on Cape Breton Island. Many of Nova Scotia's rivers rise and fall with the tides near their mouths, and carry salt water inland. Dikes protect some lowlands from rivers that could overflow their banks at high tide.

Nova Scotia has more than 400 lakes. Most of them are small. Bras d'Or Lake, the largest, covers 360 square miles (932 square kilometers) on Cape Breton Island. This saltwater lake nearly divides the island in two. The largest freshwater lakes are, in order of size, Lake Rossignol in Queens County, Lake Ainslie on Cape Breton

Sherman Hines, Masterfile

The southern coastline of Nova Scotia has many inlets. Numerous small islands lie off the province's southern shore.

Island, Kejimkujik Lake in Queens and Annapolis counties, and Grand Lake near Halifax.

Plant and animal life. Forests cover about 75 percent of Nova Scotia. Birch, firs, maples, pines, and spruces are the most common trees. Other plants found in the province include the blueberry, bracken, lambkill, mayflower, raspberry, rhodora, sweet fern, and wintergreen.

The white-tailed deer is Nova Scotia's most common large animal. Some black bears, coyotes, moose, and wildcats also live in wilderness areas. Small animals of Nova Scotia include beavers, minks, muskrats, otters, porcupines, red foxes, skunks, and weasels. The province has several kinds of geese and ducks, as well as pheasants, ruffed grouse, and woodcocks. Salmon and trout swim in the streams of Nova Scotia. The coastal waters of the province contain clams, crabs, cod, flounder, haddock, halibut, herring, lobsters, mackerel, pollock, redfish, scallops, and swordfish.

Climate. The sea nearly surrounds Nova Scotia and keeps the climate from becoming extremely hot or cold. The province has an average January temperature of 23 °F (−5 °C). The average July temperature is 64 °F (18 °C). The Atlantic coast is the coolest area of Nova Scotia in summer, but it has the mildest temperatures in winter. The interior and north have hotter summers and colder winters. But even in these areas, winter temperatures seldom fall below 0 °F (−18 °C). In winter, coastal areas of the northern mainland and western Cape Breton Island are chilled by winds crossing the ice-filled Gulf of St. Lawrence.

In spring and early summer, fogs are frequent along the Atlantic and Fundy coasts. Late summer and autumn bring sunny skies and pleasant southwesterly winds to the southern coast of the province.

The province's highest temperature, 101 °F (38 °C), oc- curred at Collegeville, near Antigonish, on Aug. 19, 1935 Upper Stewiacke recorded Nova Scotia's lowest temper ature, −42 °F (−41 °C), on Jan. 31, 1920.

Nova Scotia's *precipitation* (rain, melted snow, and other forms of moisture) averages 53 inches (134 centimeters) a year. Rainfall in the province is heaviest along the Atlantic coast. Annual snowfall is highest where onshore winds blow onto highlands and is greater than 100 inches (250 centimeters) in the Cape Breton Highlands. The lowlands and the Atlantic coast usually receive less than 70 inches (180 centimeters) a year.

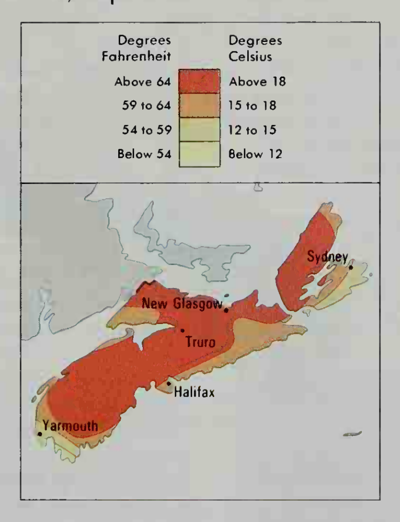
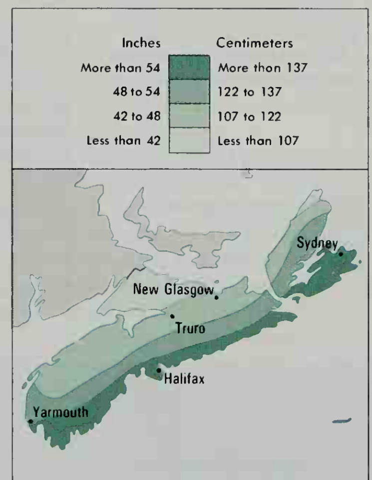
Nova Scotia Communications and Information Ce

The Northern Highlands region includes steep bluffs on Cape Breton Island. Cabot Trail, *above,* winds along the northern part of the island and is a favorite route for visitors.



Average January temperatures

The North Atlantic coast from Sydney to Yarmouth is the mildest area of the prov- nce during the wintertime.



Average July temperatures

Nova Scotia has cool summers along the foggy Atlantic coast. Inland and to the north, temperatures are warmer.

Average yearly precipitation

The Atlantic coastal area is the wettest part of Nova Scotia. Precipitation declines toward the northwest.

VORLD BOOK maps; based on the *National Atlas of Canada.*

Economy

The vast majority of Nova Scotia's workers find jobs in ervice industries, which include activities such as ealth care, retail trade, education, tourism, and finance. lova Scotia also has important manufacturing and fish- ıg industries.

Natural resources. Nova Scotia's most valuable re- ɔurces include its mineral deposits, forests, and fertile ıwlands.

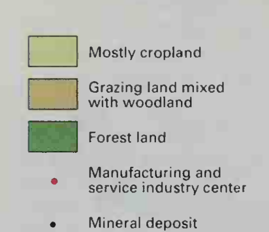
Soil. The Annapolis Valley has the best farmland. ther good farming areas include the marshlands at the ead of the Bay of Fundy, the central lowlands near uro, and the coastal lowlands along the Northumber- nd Strait. The Northern Highlands and Atlantic Plateau gions have shallow, rocky soil.

Minerals in Nova Scotia include two of North Ameri- ı's largest deposits of gypsum, at Windsor and East lilford. Although the province's last coal mine closed in)01, significant coal deposits still lie underground from ignecto on the Nova Scotia mainland to Glace Bay on ıpe Breton Island. Natural gas and oil deposits lie be- ath the shallow waters around Sable Island. Other im- ɔrtant mineral resources include barite, clay, lime- ɔne, peat, salt, and sand and gravel.

Service industries, taken together, produce the larg- t portion of Nova Scotia's *gross domestic product* DP)—the total value of all goods and services pro- ıced in the province in a year. Community, business, d personal services form the province's leading serv- industry. Businesses in this industry group include ucational, health care, and recreational facilities; engi- ering and legal firms; and hotels and restaurants. ımmunity, business, and personal services employ ɔre people than any other service industry group in ıva Scotia.

Finance, insurance, and real estate form the prov- e's second-ranking service industry. Halifax is the center of both finance and wholesale and retail trade in the Atlantic Provinces. Other service industries are government, and transportation and communication. The federal and provincial governments are major employers in Nova Scotia. Information about transportation and communication can be found later in this section.

Production and workers by economic activities



Economic activities	Percent of GDP* produced	Employed workers: Number of people	Employed workers: Percent of total

Manufacturing. Nova Scotia's manufactured products have a *value added by manufacture* of about $2\frac{1}{2}$ billion Canadian dollars yearly. This figure represents the difference between the value of raw materials and the

Economy of Nova Scotia

This map shows the economic uses of land in Nova Scotia and where the province's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

value of finished products manufactured from them.

Food and beverage processing is the leading manufacturing activity in Nova Scotia. Fish products provide much of the income. Dozens of fish-processing plants are scattered along the coast. Other important processed foods include dairy products, meat and poultry products, and preserved fruits.

Paper products rank second in importance among Nova Scotia's manufactured products. The province's paper products include newsprint and cardboard containers. Major centers of production include the Hantsport, Liverpool, Pictou, and Port Hawkesbury areas.

Tires and transportation equipment rank next in value among the province's manufactured products. Large Michelin tire plants operate near Bridgewater, Kentville, and New Glasgow. Establishments in Nova Scotia manufacture aircraft parts and boats. The province's other manufactured products include printed materials, wood products, and petroleum products. The Halifax area has an oil refinery.

Fishing. Nova Scotia ranks first among the provinces in the value of fish caught. Lobsters are Nova Scotia's most valuable catch. Other leading catches are scallops, herring, shrimp, and crab. The once-important cod stocks in the waters around Nova Scotia have been greatly depleted. *Aquaculture* (fish farming) has become increasingly important in sheltered waters along the Atlantic coast and Bras D'Or Lake.

Mining. Nova Scotia's most valuable mineral products are natural gas, petroleum, and gypsum. Natural gas and petroleum are mined near Sable Island, off Nova Scotia's southeastern coast. Gypsum comes from Hants, Inverness, and Victoria counties. Nova Scotia's other mineral products include crushed stone, peat, salt, and sand and gravel.

Agriculture. Nova Scotia has about 4,500 farms. Farmland covers about 8 percent of the province's land area.

Livestock and livestock products provide most of the province's farm income. Milk is the leading farm product. The chief dairying regions are in Colchester County and the Annapolis Valley. Other leading farm products include beef cattle, chickens and eggs, and hogs.

Blueberries and apples are the most valuable crops grown in Nova Scotia. Potatoes, strawberries, and tobacco are also important. Other agricultural activities include the operation of mink farms and Christmas tree nurseries.

Forestry. Nova Scotia's forests supply wood for its pulp and paper mills, lumber mills, boatyards, and furniture factories. Maple and yellow birch are the chief hardwoods of the province. The chief softwoods include balsam fir and spruces.

Electric power. Power plants fueled by coal, oil, and natural gas generate about 90 percent of Nova Scotia's electric power. Hydroelectric plants supply most of the rest. The first tidal power plant in North America operates at the mouth of the Annapolis River.

Transportation. Nova Scotia's major provincial highways run mainly along the coastal areas of the western part of the province. Part of the Trans-Canada Highway stretches from Amherst to North Sydney. Automobiles and trains travel $1\frac{1}{2}$ miles (2.4 kilometers) from the Nova Scotia mainland to Cape Breton Island over a *causeway* (elevated road) built across the Strait of Canso.

Halifax has the province's largest airport and seaport. Sydney and Yarmouth also have major airports. Railways link Nova Scotia's largest cities to a national railroad network. Ferries and other passenger ships connect coastal towns with ports in Maine, New Brunswick, Newfoundland, and Prince Edward Island.

Communication. Nova Scotia has about 50 newspapers, including 8 dailies. The *Halifax Gazette,* founded in 1752, was the first newspaper published in Canada. It is still published as the *Royal Gazette* by the provincial government. Daily newspapers with the largest circulations are *The Chronicle Herald* and *Mail Star* of Halifax, *The Daily News* of Dartmouth, and *The Cape Breton Post* of Sydney.

The province has about 20 radio stations and 2 television stations. Cable television systems service many communities. The first radio station, CHNS, began broadcasting from Halifax in 1926. The first television station, CJCB-TV, began operating in Sydney in 1954.

Lieutenant governor of Nova Scotia represents the British monarch, Queen Elizabeth II, in her role as the queen of Canada. The lieutenant governor is appointed by the governor general in council of Canada. The position of lieutenant governor is largely honorary.

Premier of Nova Scotia is the actual head of the provincial government. Nova Scotia, like Canada itself, has a parliamentary form of government. The premier is an elected member of the Legislative Assembly. The person who serves as premier is usually the leader of the majority party in the Assembly.

The premier presides over the Executive Council (cab-inet). The Council is made up of the premier and other ministers. All the ministers belong to the Assembly's ma-ority party. They are chosen by the premier. Each Coun-cil member usually directs one or more governmental departments. The Council resigns if it loses the support of a majority of the Assembly.

Legislative Assembly makes the provincial laws. This one-house legislature has 52 members elected by he people. An election for the Assembly must be held at least every five years. But the lieutenant governor, on he advice of the premier, may call for an election at any ime. A premier who loses the support of the majority of he Assembly must resign, and a new election is held.

Courts. Nova Scotia has a superior court system with wo divisions, the Supreme Court and the Court of Ap-peal. The Supreme Court consists of a chief justice, an ssociate chief justice, and 23 other judges. The Court of Appeal consists of a chief justice and 8 other judges. he chief justice of the Court of Appeal also serves as he chief justice of Nova Scotia.

The governor general in council appoints the prov-nce's Superior Court judges, who may serve until the ge of 70. The lieutenant governor appoints provincial udges, justices of the peace, and judges of the probate nd family courts, all of whom may serve until age 65.

Local government. Nova Scotia has 18 counties, 3 egional municipalities, and 31 towns. Voters from each egional municipality and town elect a mayor and a ouncil. All other communities are part of 21 districts alled rural municipalities. Nine counties are single rural unicipalities, six are divided into two rural municipali-es apiece, and the other three are regional municipalities. An elected council governs each rural municipality. Members of the council, called councilors, elect a *warden* (chief councilor) from their group.

Revenue. Nova Scotia gets more than half of its *general revenue* (income) from taxes levied by the provincial government. Most of this money comes from taxes on income and on goods and services. Sales of gasoline and tobacco products are also taxed. Other sources of revenue include national and provincial tax-sharing programs and license and permit fees.

Politics. Nova Scotia's leading political organizations are the Liberal Party, the Progressive Conservative Party, and the New Democratic Party. An earlier Conservative Party changed its name to the Progressive Conservative Party in 1942. Since 1867, when Nova Scotia became a province, Liberals have held the office of premier about twice as long as have Conservatives.

The premiers of Nova Scotia

	Party	Term

Nova Scotia Government Services

The Nova Scotia Legislative Assembly meets in chambers in Province House in Halifax. The Assembly's 52 members are elected to terms of up to five years.

History

Indian days. Human beings have lived in Nova Scotia for at least 10,000 years. The earliest people, called Paleo Indians, were hunters who lived mainly off herds of caribou. Their successors, the Micmac, hunted and fished along the coast in the summer and in the forested interior during the winter. See **Micmac Indians**.

Exploration and settlement. The English explorer John Cabot may have landed in Nova Scotia or in Newfoundland as early as 1497. Cabot believed he had landed in Asia. Between 1520 and 1524, several other explorers reached Nova Scotia while trying to find a westward sea route to Asia. They included the Italian navigator Giovanni da Verrazzano and two Portuguese sailors, João Alvarez Fagundes and Estevan Gomez. Verrazzano explored in the service of France. Gomez sailed in the service of Spain. During the summers of the late 1500's, French fishermen used the Nova Scotia shore for drying codfish they had caught nearby. These fishermen returned to France every autumn.

In 1603, King Henry IV of France gave land including Nova Scotia to a French explorer, Pierre du Gua (or du Guast), Sieur de Monts. De Monts and another French explorer, Samuel de Champlain, sailed along the Nova Scotia coast in 1604. Champlain made the first accurate chart of the coast. The Nova Scotia region and the land around it became known as *Acadia* (see **Acadia**). De Monts and Champlain established a colony in the New Brunswick region near the mouth of the St. Croix River. In 1605, this colony was moved to Nova Scotia and became Port Royal. This settlement was initially designed to provide an outpost for the fur trade. It was also supposed to serve as a center for French attempts to convert the Micmac to Christianity. By the mid-1600's, most settlers worked as farmers.

The struggle in Acadia. In 1613, the French colony at Port Royal was captured and burned by English raiders from Virginia. Samuel Argall, a sea captain, led the attack. For over a hundred years the English and the French battled, off and on, for control of Acadia.

In 1621, King James I of England and Scotland made a land grant to Sir William Alexander. The grant included what is now Nova Scotia and also New Brunswick, Prince Edward Island, part of Quebec, and part of Maine. Alexander named the region *Nova Scotia,* Latin for *New Scotland.* In 1629, Alexander's son, Sir William the younger, built a new fort at Port Royal. But the colony lasted only until 1632.

France received Port Royal in 1632 under the Treaty of St. Germain-en-Laye. Colonists sent by a French company took control of Port Royal and also settled at La Have. The settlers became known as Acadians. In 1636, the French reestablished Port Royal, at what is now the town of Annapolis Royal, when they built a fort there.

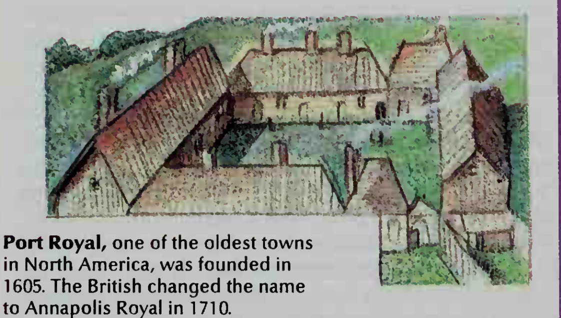
English troops under Sir William Phips captured Port Royal in 1690. But England gave Port Royal back to France under the Treaty of Ryswick in 1697. A combined force of troops from England and New England took Port Royal again in 1710. That year, the British changed the name of the fort from Port Royal to Fort Anne. The nearby town became known as Annapolis Royal.

France gave up the mainland of Nova Scotia under the Treaty of Utrecht in 1713. This treaty made British subjects of the French who stayed in Nova Scotia. The treaty also gave Cape Breton Island (then called *Ile Royale*) and Prince Edward Island (then called *Ile Saint Jean*) to France. The French built a fortress at Louisbourg on Cape Breton Island to assert their power in the region. British troops from New England captured the fortress in 1745 with the aid of the Royal Navy. France regained it in 1748 under the Treaty of Aix-la-Chapelle, which settled a European war. But Louisbourg fell to the British during the Seven Years' War (1756-1763).

British settlers established Halifax in 1749. It became Nova Scotia's capital the same year. Many French, German, and Swiss Protestants came to Nova Scotia in the early 1750's to escape religious persecution in Europe. In 1755, British colonial troops from New England began to drive out of Nova Scotia the Acadians who refused to swear complete allegiance to Britain. Many Acadians died in this upheaval, and thousands fled to Prince Edward Island, Quebec, the French colony of Louisiana, France, and British colonies in America. But by the 1760's, Acadian survivors began to return to Nova Scotia.

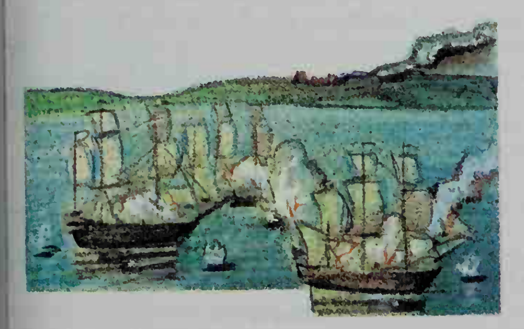
Progress as a province. In 1758, the British government allowed colonists in Nova Scotia to elect a representative assembly. The first assembly met in Halifax. It

Yale University Art Gallery



The First Battle of Louisbourg was a key British victory during the French and Indian wars. British troops from New England helped capture the French fortress of Louisbourg in 1745.

Historic Nova Scotia



Giovanni da Verrazzano, an Italian navigator, sailed along the coast of Nova Scotia in the service of France in 1524. He was one of the first people to explore the coast.

Halifax was founded in 1749 by the English governor Edward Cornwallis. He made Halifax the capital of Nova Scotia.

Port Royal, one of the oldest towns in North America, was founded in 1605. The British changed the name to Annapolis Royal in 1710.

The first British victory in Nova Scotia occurred when seamen captured and burned Port Royal in 1613.

British colonial troops from New England began in 1755 to drive French Acadians away from Nova Scotia.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Nova Scotia

1497-1524 European explorers reached Nova Scotia while seeking a sea route to Asia.

1603 King Henry IV of France commissioned Pierre du Gua, Sieur de Monts, to colonize Acadia.

1604 Samuel de Champlain charted the Nova Scotia coast.

1605 Champlain and De Monts founded Port Royal.

1710 The British captured Port Royal and changed its name to Annapolis Royal.

1713 Under the Treaty of Utrecht, France gave Britain the mainland of Nova Scotia.

1749 The British founded Halifax.

1755 British colonial troops from New England began to drive out of Nova Scotia Acadians who would not swear allegiance to Britain.

1758 The first provincial parliament of Nova Scotia met in Halifax.

1776-1785 United Empire Loyalists came to Nova Scotia from the United States.

1848 Nova Scotia became the first part of Canada to get *Responsible Government* (local self-government).

1867 Nova Scotia joined with New Brunswick, Ontario, and Quebec in forming the Dominion of Canada.

1917 A French munitions ship exploded in Halifax Harbour and killed about 2,000 people.

1939-1945 Halifax became a base for convoys sailing to and from Europe during World War II.

1967 Parliament established the Cape Breton Development Corporation to attract new industry to the area.

gave the people some voice in their government. But a governor and a council appointed by the king really ruled the province. In 1763, the Peace of Paris officially gave Cape Breton Island to Britain.

In 1760, more than 20 ships carrying New Englanders arrived in Nova Scotia. The New Englanders took over the land the Acadians had cleared, and they established many new settlements. During and after the Revolutionary War in America (1775-1783), about 35,000 people came to Nova Scotia from the United States. Most of the people, called Loyalists or United Empire Loyalists, were British colonists in America who refused to fight against Britain in the Revolutionary War. They established Shelburne and also settled in Guysborough, Digby, and other towns. Some Loyalists were blacks who had been promised freedom from slavery in Nova Scotia.

Protestant and Roman Catholic settlers from Scotland began arriving in Nova Scotia in 1773. They continued to immigrate in large numbers for over 50 years, becoming a major group in eastern Nova Scotia. Irish Catholic immigrants also arrived in the early 1800's, settling chiefly in and around Halifax. More blacks came from the United States during the War of 1812 (1812-1815).

Nova Scotians gained control over local affairs in 1848 when the British government granted Nova Scotia a governing council controlled by the elected assembly. Nova Scotia became the first completely self-governing colony within the British Empire. Joseph Howe, a forceful editor and statesman of Nova Scotia, had led the fight to win the new government for the colony.

During the 1800's, Nova Scotia thrived with growing industries and increasing world trade. Shipbuilders used timber from the province's forests to build merchant ships. By 1860, Nova Scotia had one of the largest merchant fleets in the world.

In 1867, Nova Scotia joined with New Brunswick, Ontario, and Quebec in forming a confederation called the Dominion of Canada (see **British North America Act**). The next 25 years brought economic hardship to Nova Scotia. During this time, investors abandoned shipping in an effort to industrialize Nova Scotia. However, this effort failed. But during the late 1890's, Nova Scotia's steel industry and coal production began to thrive.

The early to middle 1900's. During World War I (1914-1918), Halifax served as the headquarters of Allied convoys sailing between North America and Europe. In 1917, a French military supply ship exploded in Halifax Harbour. The blast killed about 2,000 people and damaged much of the city.

During the next 20 years, the province experienced an economic crisis and political unrest. Many people left Nova Scotia. After a brief period of bustle during World War II (1939-1945), hard times returned to the province.

In the mid-1950's, Canada's overall postwar prosperity began to trickle down to Nova Scotia. The economy of the province grew. Schools, hospitals, and a modern network of roads were constructed. The Nova Scotia section of the Trans-Canada Highway was built across the province. In 1955, the Canso Causeway, linking the mainland and Cape Breton Island, was completed. It contributed to the province's economic growth and to expansion of the tourist industry. In this period, the rural population of Nova Scotia declined. But people migrated to urban areas within the province rather than to other parts of Canada or to New England.

Beginning in the 1950's, Canada's federal government and Nova Scotia's provincial government worked to promote economic growth within Nova Scotia. A series of provincial and federal agencies were created that sought to close outdated industries and attract new ones. These agencies included Industrial Estates Limited (established in 1957), the Cape Breton Development Corporation (1967), Sydney Steel Corporation (1969), and Nova Scotia Power Corporation (1973).

The expansion of industry and port facilities helped improve Nova Scotia's economy in the 1970's. For example, a container terminal opened in 1970 at the Port of Halifax to handle large container ships. During the early 1970's, an industrial park was built on the shores of the Strait of Canso.

Recent developments. Several important economic developments took place in Nova Scotia during the 1980's and early 1990's. Facilities were expanded at the Port of Halifax. Oil production began around Sable Island. On the other hand, the decline of several industries hurt the provincial economy. For example, the once-important cod fishery of the province virtually collapsed due to overfishing, and coal mining in Pictou County closed down.

Today, Nova Scotia faces a number of economic problems. A slowdown in Canada's overall economy and efforts to balance the federal budget have reduced the amount of federal funds available for Nova Scotia. As a result, government enterprises have been cut back. Both Nova Scotia Power and Sydney Steel have been sold to private investors. Municipal governments, hospital and school boards, and institutions of higher education are being combined to save money. Gambling casinos have been legalized to provide the province with a source of income. Hugh Millward and D. A. Sutherland

Novalis, *noh VAH lihs* (1772-1801), was the pen name of Baron Friedrich von Hardenberg, a German romantic poet. Five poems by Novalis, called *Hymns to the Night* (1800), express his religious, mystical nature, and a longing for death. In the essay *Christianity or Europe* (1799), Novalis tried to show that people lived more meaningful lives in the spiritual unity of the Catholic Middle Ages than in his own time. This attitude became a theme of German romanticism.

Novalis was born in Saxony. The death of his 15-year-old fiancée in 1797 deepened his melancholy and his religious temperament. Novalis's work as a mining engineer brought him close to the land and intensified his love of nature and its mysteries. Jeffrey L. Sammons

Novaya Zemlya, *NOH vuh yuh ZEHM lee AH,* is a group of islands in the Arctic Ocean that separate the Barents Sea from the Kara Sea. The islands are part of Russia. The Russian name means *new land* and commonly refers to the two largest islands. The northern large island covers about 20,000 square miles (52,000 square kilometers). Glaciers blanket much of it. The southern large island has an area of about 15,000 square miles (38,800 square kilometers), most of which is a treeless plain. Both islands have large deposits of coal and some copper, lead, and zinc.

Early Russians first discovered Novaya Zemlya between the 1000's and 1100's. But the islands remained uninhabited until 1877, when an Arctic people called Samoyeds established the first permanent settlements.

A small colony of Russians and Samoyeds live on the southern island. Islanders raise reindeer, trap and hunt animals, and collect *eider down* (the feathers of eider ducks). The Soviet Union tested nuclear bombs on the northern island in the 1950's. Today, the island shows harmful levels of radiation. Craig ZumBrunnen

Novel is a long fictional story written in prose. It is one of the most popular forms of literature.

The subject matter of novels covers the whole range of human experience and imagination. Some novels portray true-to-life characters and events. Writers of such *realistic novels* try to represent life as it is. In contrast to realistic novels, *romantic novels* portray idealized versions of life. Some novels explore purely imaginary worlds. For example, *science-fiction novels* may describe events that take place in the future or on other planets. Other popular kinds of novels include detective novels and mysteries, whose suspenseful plots fascinate readers.

Some novels point out evils that exist in society and challenge the reader to seek social or political reforms. Novels may also provide knowledge about unfamiliar subjects or give new insights into familiar ones.

The novel has four basic features that together distinguish it from other kinds of literature. First, a novel is a *narrative*—that is, a story presented by a teller. It thus differs from a drama, which presents a story through the speech and actions of characters on a stage.

Second, novels are longer than short stories, fairy tales, and most other types of narratives. Novels vary greatly in length, but most exceed 60,000 words. Because of their length, novels can cover a longer period and include more characters than can most other kinds of narratives.

Third, a novel is written in prose rather than verse. This feature distinguishes novels from narrative poems.

Fourth, novels are works of fiction. They differ from histories, biographies, and other long prose narratives that tell about real events and people. Novelists sometimes base their stories on actual events or the lives of real people. But these authors also make up incidents and characters. Therefore, all novels are partly, if not entirely, imaginary.

The basic features of the novel make it a uniquely flexible form of literature. Novelists can arrange incidents, describe places, and represent characters in an almost limitless variety of ways. They also may narrate their stories from different points of view. In some novels, for example, one of the characters may tell the story. In others, the events may be described from the viewpoint of a person outside of the story. Some novelists change the point of view from one section of a story to another. Novelists also vary their treatment of time. They may devote hundreds of pages to the description of the events of a single day, or they may cover many years within a few paragraphs.

Origins of the novel

This article discusses the development of the novel in Western literature. The history of the novel is marked by

an almost continual development of variations on old narrative forms. No matter how up to date or localized novels may seem, their stories still employ many themes and issues from narrative forms dating back to the ancient Greeks and Romans.

Ancient Greek and Roman narratives. In ancient times, most long narratives were composed in verse. Histories were among the few kinds of long narratives written in prose. The earliest known histories were written by two Greek authors, Herodotus and Thucydides, during the 400's B.C.

The finest fictional narratives of ancient Greece were long poems called *epics,* which told about the deeds of legendary heroes and mythical gods. The *Iliad* and the *Odyssey,* the two most famous epics, were probably composed by Homer between 800 and 700 B.C.

The Greeks also wrote long fictional adventure stories. These tales described fantastic adventures in foreign countries or related the plights of young lovers. Some writers composed *pastoral* tales, which told of love between shepherds and maidens. One of the best-known Greek pastorals is *Daphnis and Chloe* (A.D. 100's or 200's) by Longus.

The most important Roman narratives in prose included *Satyricon* (about 60 A.D.) by Petronius and *Metamorphoses,* or *The Golden Ass* (mid-100's A.D.), by Lucius Apuleius. These earthy stories contrast sharply with the love stories of the Greeks. *Satyricon* vividly portrays the adventures of three Roman scamps. *Metamorphoses* tells of a man who is changed into a donkey and travels through various countries observing the weaknesses and failings of humans.

Medieval narratives. The word *novel* originally referred to prose stories that were topical. The word for *novel* in French and other languages deriving from classical Latin is *roman.* The word reflects the fictions called *romances* in which it had its roots. Love and adventure stories called *romances of chivalry* became widely popular during the late Middle Ages. Many of the romances dealt with the legendary British King Arthur and his Knights of the Round Table.

Early novels. During the 1500's and 1600's, many English romances were written in an extremely decorative style. After John Lyly of England wrote *Euphues: The Anatomy of Wit* (1578), this highly artificial style was called *euphuistic* and was widely imitated. In France, many romances and romance histories were written by important women writers. Madeleine de Scudéry wrote historical narratives, such as *Artamene, or The Great Cyrus* (1649-1653). Marie-Madeleine de La Fayette wrote the most psychologically powerful of these novels, *The Princess of Cleves* (1678).

In Spain, several narratives that were more realistic appeared during the 1500's. One of the most influential was *Lazarillo de Tormes* (1554), by an unknown Spanish author. Some critics consider it the first *picaresque novel.* These novels describe the adventures of a young *picaro* (rogue) who makes his way in the world through cunning and treachery. Picaresque novels are episodic like romances about knights, but in *Lazarillo de Tormes,* the rogue replaces the knight as the hero.

The first classic novel, according to some critics, was the Spanish masterpiece *Don Quixote* (part I 1605, part II 1615) by Miguel de Cervantes. Cervantes's story combines the chivalric romance and the picaresque adventure. The central character in *Don Quixote* is a middle-aged country landowner who imagines himself a knight, battling injustice. He differs significantly from the unbelievably heroic or clever characters in romances and picaresque narratives. Cervantes's characters resemble real people and often make foolish and costly mistakes.

The rise of the English novel

The novel form tends to emphasize realistic social themes. Sophisticated novels of this kind first appeared in England in the early 1700's. At that time, the urge to record the details of ordinary life began to replace the older narrative focus on wondrous, supernatural, remote, and heroic material.

The first English novelists. Some critics regard Daniel Defoe as the first novelist, though others credit Aphra Behn with combining the novel form and the romance in her fascinating slave narrative, *Oroonoko* (1688). Defoe's *Robinson Crusoe* (1719) and *Moll Flanders* (1722) consist of a series of episodes in the lives of clever and resourceful, but ordinary, characters.

Samuel Richardson wrote novels with well-developed plots rather than a sequence of episodes. His *Pamela; or Virtue Rewarded* (1740) tells of a virtuous female servant who resists her master's attempts to seduce her. The story is told in the form of letters, most of which are written by Pamela, the heroine, to her family. Through the letters, Richardson reveals key psychological aspects of the central character.

Henry Fielding wrote *The History of Tom Jones, a Foundling* (1749), which is especially noted for its elaborate, unified plot. This novel tells of the comical adventures of a young orphan, first as he grows up in rural England, and then as he travels toward London, meeting a variety of characters in English life.

Tobias Smollett wrote amusing, loosely constructed novels about eccentric characters. *The Expedition of Humphry Clinker* (1771) is a novel in letter form about a variety of English travelers and personality types.

Laurence Sterne was one of the greatest experimenters in the history of the novel. *The Life and Opinions of Tristram Shandy, Gentleman* (1760-1767). *Tristram Shandy* is an unconventional novel about an unconventional family. The story humorously portrays character types, philosophical ideas, and social customs.

Gothic novels became widely popular in England during the late 1700's through the 1800's. These horror stories tell of mysterious events that take place in gloomy, isolated castles. They have suspenseful, action-packed plots. Mary Shelley's *Frankenstein* (1818), about a scientist who creates a monster from parts of dead bodies, and Bram Stoker's *Dracula* (1897), about a nobleman who is secretly a vampire, became the most enduring examples of the type.

The 1800's

During the 1800's, English writers elaborated on the techniques of the early novelists and produced many great works. Authors in France, the United States, and Russia also wrote novels of major literary importance. The *romantic movement,* which stressed the need for full expression of human emotions and imagination, dominated the literature of the early 1800's. It was fol-

lowed by the *realistic movement,* which demanded that literature accurately represent life as it is.

Britain. Sir Walter Scott, a Scottish writer, created and popularized *historical novels.* Such novels re-create the atmosphere of a past period and include actual characters and events from history. Scott wrote a long series of historical novels, including *Waverley* (1814), about a Scottish rebellion against England.

The *novel of manners* appeared in England during the late 1700's. Fanny Burney was one of the first writers in the tradition with *Evelina* (1778), a novel about a young woman's introduction to London life. Jane Austen perfected the novel of manners in the early 1800's. Her masterpiece, *Pride and Prejudice* (1813), centers on the social conventions surrounding courtship and marriage.

The English novel flourished during the 1800's, expanding to explore society's classes and institutions. Emily Bronte's *Wuthering Heights* (1847) added both Gothic and romance elements to the novel of manners. Charlotte Bronte's *Jane Eyre* (1847) merged Gothic romance and fictional biography. William Makepeace Thackeray wrote satirically on the hypocrisies of life in London and Paris in *Vanity Fair* (1847-1848). Charles Dickens wrote many great novels about English urban life. *Oliver Twist* (1837-1839) deals with the London underworld.

Anthony Trollope wrote long, detailed novels centering on politics, society, and religion as in the witty *Barchester Towers* (1857). George Eliot portrayed English rural and small-town life. Her greatest work, *Middlemarch* (1871-1872), deals with the profound moral crises in the lives of landowners and rural professionals. Robert Louis Stevenson wrote *Treasure Island* (1883) and other popular adventure novels. In the late 1800's, Thomas Hardy wrote novels such as *Jude the Obscure* (1895), in which tortured characters were fated to lead desperate lives.

France. French writers greatly influenced the development of the novel in the 1800's. Honoré de Balzac wrote a series of novels in the 1830's and 1840's under the collective title *The Human Comedy.* These were the first novels to fully explore the manners and morals of an entire society. Stendhal contributed to the development of the psychological novel in *The Red and the Black* (1830) and to the political novel in *The Charterhouse of Parma* (1839). Alexandre Dumas *père* and Victor Hugo wrote massive historical novels. The most famous include Dumas's *The Count of Monte Cristo* (1844-1845) and Hugo's *Les Misérables* (1862).

Gustave Flaubert wrote *Madame Bovary* (1856), which tells about a woman unhappy in her marriage to a village doctor. Flaubert's precise objective style influenced many other writers. Émile Zola helped establish *naturalism* as an important literary movement in the late 1800's. According to the theory of naturalism, a person's life is determined by heredity and environment. Naturalistic novels portray people who are trapped by circumstances beyond their control. Many of these novels deal with grim subjects. Zola's *Germinal* (1885), for example, describes the suffering of French miners.

The United States. The early American novel was less concerned with social and historical tradition than the European novel. From its beginnings, the American novel explored intense family themes, as in Charles Brockden Brown's *Wieland* (1798), about a man who goes insane and murders his wife and children. American novels also dealt with the frontier landscape, as in James Fenimore Cooper's *The Last of the Mohicans* (1826). Cooper's novel includes one of America's great folk heroes, the frontiersman Natty Bumppo.

The mid-1800's produced classic American novels of moral dilemmas and obsession. Nathaniel Hawthorne's tale of sin, *The Scarlet Letter* (1850), and Herman Melville's symbolic whaling story, *Moby-Dick* (1851), are examples. Harriet Beecher Stowe's *Uncle Tom's Cabin* (1851-1852) was one of the first novels to raise the nation's consciousness about slavery.

In the late 1800's, Mark Twain captured American humor and colloquial speech in *The Adventures of Tom Sawyer* (1876) and *Adventures of Huckleberry Finn* (1884). The later book in particular has been praised for its attack on the social evils of the day and its vivid and realistic portrait of life on the Mississippi River.

William Dean Howells, in his novel *The Rise of Silas Lapham* (1885), became the first American writer to draw on the tradition of social realism coming out of European fiction in the 1800's. Henry James has been acclaimed for his psychological portrayals of sensitive, intelligent characters. James spent much time in England and followed the English tradition of writing about social manners in *The Portrait of a Lady* (1880-1881) and other novels.

During the late 1800's and early 1900's, the French naturalist movement influenced many American writers, notably Stephen Crane, Theodore Dreiser, Frank Norris, and Upton Sinclair. Crane's first novel, *Maggie: A Girl of the Streets* (1893), portrays the cruelty and vulgarity of slum life. Dreiser's *Sister Carrie* (1900) tells of a poor, lonely woman in Chicago. Norris's *The Octopus* (1901) depicts the expansion of the American railroad. Sinclair's *The Jungle* (1906) attacked the Chicago-based meatpacking industry so effectively that the novel led directly to government reforms.

Russia produced its two greatest novelists, Leo Tolstoy and Fyodor Dostoevsky, during the 1800's. Tolstoy and Dostoevsky rank as masters of the realistic novel.

Tolstoy's famous masterpiece, *War and Peace* (1869), centers on the 1812 invasion of Russia by the French emperor Napoleon I. The account of the war is interwoven with stories about the lives of several Russian families. Dostoevsky won fame for his probing psychological insight and his treatment of philosophical ideas. In his novel *Crime and Punishment* (1866), he explored the anguished mind of a student who commits two murders.

The modern novel

During the 1900's. Novelists experimented with various styles, techniques, and types of plots. World War I (1914-1918) had a major impact on many writers. The noble ideals and high hopes with which nations entered the war were shattered by the length and destruction of the conflict. After the war, many novelists dealt with the social changes and personal disillusionments of modern times. After World War II (1939-1945), novelists continued to explore the problems of modern life, especially the threat of nuclear war.

New directions in the novel. Older forms of the novel persisted in the early 1900's, notably in the works of Arnold Bennett and Rudyard Kipling in England. How-

ever, more experimental novelists began to gain prominence. In such novels as *Nostromo* (1904), the Polish-born English novelist Joseph Conrad changed the form of the adventure story. Conrad's stylistic experiments and probing psychological analysis helped shape the future of the novel in the 1900's.

In England, D. H. Lawrence broke many social taboos in writing about sexual passion in such novels as *Women in Love* (1920). Ford Madox Ford experimented with narration in *The Good Soldier* (1915), in which the narrator discovers that his wife and his best friend have been lovers for years. E. M. Forster raised issues of class and race in *A Passage to India* (1924).

Marcel Proust of France wrote the masterpiece *Remembrance of Things Past* (1913-1927). This seven-part novel deals with many subjects and portrays French society in the process of change during the early 1900's. The hero of French author Louis-Ferdinand Céline's *Journey to the End of the Night* (1932) wanders aimlessly through war-torn Europe.

The Irish writer James Joyce became one of the greatest novelists of the 1900's. In *Portrait of the Artist as a Young Man* (1916), a largely autobiographical novel about his youth, Joyce began to use techniques of narration in which the author presents the thoughts, sensations, and memories that flow through a character's mind. He perfected this technique, called *interior narration,* or *stream of consciousness,* in *Ulysses* (1922). This challenging novel compares one day in the life of a 1904 Dublin resident with events in Homer's *Odyssey.*

The English author Virginia Woolf also experimented with interior narration. Her best novels, such as *To the Lighthouse* (1927), are known for their brilliant structure and the emotional power of their style.

The greatest American novelists of the early 1900's included Edith Wharton, Sinclair Lewis, F. Scott Fitzgerald, Ernest Hemingway, William Faulkner, and John Steinbeck. Wharton followed Henry James in such novels of manners as *The Age of Innocence* (1920), about aristocratic New Yorkers of the 1870's. Lewis wrote about middle-class Americans in *Babbitt* (1922). In *The Great Gatsby* (1925), Fitzgerald pictured the false glamour and moral emptiness of wealthy, pleasure-seeking Americans of the 1920's, an era called the *Jazz Age.* Hemingway captured the personal letdown and sense of loss that many people felt after World War I in *The Sun Also Rises* (1926). In *The Sound and the Fury* (1929) and other novels, Faulkner dealt with the decline of Southern aristocratic families and the breakdown of traditional standards of behavior. Steinbeck wrote about the Great Depression in such powerful novels as *The Grapes of Wrath* (1939).

The American detective novel made a significant contribution to the modern novel with its realistic language and cynicism. The most important of these novels included *The Maltese Falcon* (1930) by Dashiell Hammett and *The Big Sleep* (1939) by Raymond Chandler.

Franz Kafka, a Czech author who wrote in German, produced puzzling novels that have an atmosphere of fantasy and nightmare. In *The Trial* (1925), Kafka portrayed the frustration and despair of an ordinary man entangled in the workings of a bureaucratic legal system. The German novelist Thomas Mann also wrote about the frustrations of modern life, but the main characters in his novels are sensitive and intellectually gifted. Mann's major novels include *The Magic Mountain* (1924).

Existentialism, a philosophic movement, greatly influenced French literature during the late 1930's and the 1940's. Existentialists emphasized that individuals must choose their own way to live and act in an essentially meaningless world and then accept full responsibility for their actions. The rise of existentialism in France resulted in a number of existential novels, including *Nausea* (1938) by Jean-Paul Sartre and *The Stranger* (1942) by Albert Camus. Sartre and Camus focused on moral issues rather than on experimental techniques.

After World War II. During the 1950's, an experimental form called the *nouveau roman* (new novel) appeared in France. The nouveau roman writers rejected traditional features of novels, such as organized plots and clear-cut types of characters. Instead, they wrote novels that focused on exact descriptions of objects and events. The nouveau roman writers included Alain Robbe-Grillet, Marguerite Duras, and Michel Butor. *Jealousy* (1957) by Robbe-Grillet typifies the nouveau roman. Perhaps the most original novelist of the 1940's and 1950's was Samuel Beckett, an Irish-born author who wrote in both French and English. Beckett was influenced by James Joyce and used the interior narration technique in *Malone Dies* (1951). This novel centers on the repressed hysteria of a dying tramp named Malone.

In England, the leading postwar novelists included Evelyn Waugh, George Orwell, and Graham Greene. Waugh wrote light satirical novels before the war, but his tone later deepened in *Brideshead Revisited* (1945), a study of an aristocratic Roman Catholic family. Orwell's *1984* (1949) deals with life in a totalitarian state. Greene wrote about religious and moral problems in *The Heart of the Matter* (1948). Other postwar English novelists included Kingsley Amis, Anthony Burgess, Doris Lessing, Iris Murdoch, C. P. Snow, and Muriel Spark.

American writers produced fairly conventional novels during the 1950's. One of the most popular novels of this period was *The Catcher in the Rye* (1951) by J. D. Salinger. It tells about the problems of a prep school dropout in New York City. The novels of Saul Bellow, Philip Roth, and Bernard Malamud deal partly with Jewish life in the United States. Bellow followed the form of the picaresque narrative in *The Adventures of Augie March* (1953), about a Chicago youth who grows up during the Great Depression. In *The Assistant* (1957), Malamud portrayed the relationship between a poor Jewish shopkeeper and his helper. In *Goodbye, Columbus* (1959), Roth wrote of the strained love affair between a young middle-class Jewish man and a wealthy Jewish girl.

The American novelists Ralph Ellison and James Baldwin focused on the difficulties faced by African Americans. Ellison's *Invisible Man* (1952) describes a young black man's growing awareness of the turmoil over race in the United States. Baldwin's *Go Tell It on the Mountain* (1953) tells of a poor black family in the Harlem section of New York City. Other brilliant writers in the 1950's produced well-crafted and powerful novels. Flannery O'Connor explored religious fanaticism in the South in *Wise Blood* (1952). The Russian-born Vladimir Nabokov wrote *Lolita* (1955), a funny and controversial novel about an older man's obsession with a young girl.

The middle and late 1900's. The *black humor* style in fiction became popular during the 1960's. Black humorists treat serious subjects in a darkly comic manner. Their novels are both funny and tragic. For example, *Catch-22* (1961), by the American author Joseph Heller, deals humorously with the absurdities of warfare and military organizations, but also captures the terrifying confusion of war.

John Updike's *Rabbit, Run* (1960) is an ironic novel about suburban life in the eastern United States. Philip Roth's *Portnoy's Complaint* (1969) deals with the sexual neuroses of a young man from a Jewish family.

Science fiction played a prominent role in novels of the middle and late 1900's. Key works include *Fahrenheit 451* (1953) by Ray Bradbury, *Stranger in a Strange Land* (1961) by Robert A. Heinlein, *Dune* (1965) by Frank Herbert, *The Andromeda Strain* (1969) by Michael Crichton, *Neuromancer* (1984) by William Gibson, and *The Handmaid's Tale* (1985) by Margaret Atwood.

The novel today features international trends that appeared during the 1960's and 1970's. One of the trends was introduced by a group of authors who wrote *nonfiction novels.* These novelists combined a documentary style with fictional techniques to tell about actual events and people.

The American writer Truman Capote originated the term "nonfiction novel" to describe his *In Cold Blood* (1966). Capote based this work on an actual 1959 murder case in which two men killed a Kansas farm family. Many other American authors, including William Styron and Norman Mailer, followed Capote in writing nonfiction novels. In *The Confessions of Nat Turner* (1967), Styron told the story of an 1831 slave rebellion in Virginia led by Nat Turner, a black preacher. Mailer wrote *The Armies of the Night* (1968), which describes his experiences in a 1967 protest march in Washington, D.C.

One group of writers created highly imaginative and inventive novels. In some cases, they modernized myths, fairy tales, and other old stories, or they created fantasy worlds. Latin American fiction gained recognition with a kind of novel called *magic realism,* which blends dreams and magic with everyday reality. The originator of this style was the Argentine writer Jorge Luis Borges. The Colombian writer Gabriel García Márquez wrote a classic of magic realism, *One Hundred Years of Solitude* (1967), about generations of a strange Latin American family. Manuel Puig of Argentina wrote *Kiss of the Spider Woman* (1976), about the relationship between two men who share a prison cell. Several other Latin American novelists contributed to the tradition of magic realism, often writing in newer, more experimental forms. These authors included Carlos Fuentes of Mexico in *The Death of Artemio Cruz* (1962), Mario Vargas Llosa of Peru in *The Time of the Hero* (1962), and Luisa Valenzuela of Argentina in *The Lizard's Tail* (1983).

Postwar German novelists produced their own style of magic realism in the fiction of Günter Grass. In Grass's *The Tin Drum* (1959), the main character can stop time and drown out history. Grass wrote about postwar stress in Germany and Poland in *The Call of the Toad* (1992). Heinrich Böll dealt with postwar German memories in *Group Portrait with Lady* (1971).

The Italian writers Italo Calvino and Umberto Eco took the novel back to its roots in allegory, fable, and fairy tale. Calvino wrote *The Castle of Crossed Destinies* (1973), and Eco wrote *The Name of the Rose* (1980).

Eastern Europe produced its own style of experimental fiction, often with a political slant. Christa Wolf described the difficulty of living in East Germany before the 1990 reunification in *The Quest for Christa T.* (1968). Milan Kundera dealt with human relationships in Czechoslovakia near the time of a Russian invasion in 1968 in *The Unbearable Lightness of Being* (1984).

Another international trend in the novel was fiction that reflected the breakup of colonial empires in Africa, Asia, and the Caribbean. Some authors wrote about changes in Australia and Canada. Works reflecting these trends included the South African novels *In the Heart of the Country* (1977) by J. M. Coetzee and *Burger's Daughter* (1979) by Nadine Gordimer. Chinua Achebe used Nigerian themes in *Things Fall Apart* (1958). V. S. Naipaul wrote several highly praised novels set in the West Indies, notably *Guerrillas* (1975). Salman Rushdie wrote about Indian and Muslim traditions in *The Satanic Verses* (1988). Patrick White wrote sweeping novels about his homeland of Australia, such as *The Tree of Man* (1955). Robertson Davies wrote sophisticated novels about Canada, including *What's Bred in the Bone* (1985).

British novelists still write in a realistic style, but they have widened the range of their works. Graham Swift wrote about rural life in *Waterland* (1983). Kingsley Amis's son Martin Amis wrote about world finance in *Money: A Suicide Note* (1984). David Lodge used an academic setting in *Small World: An Academic Romance* (1984). Julian Barnes dealt with the world of ideas in *A History of the World in 10 $\frac{1}{2}$ Chapters* (1989). Jeanette Winterson explored myth and sexuality in *Sexing the Cherry* (1989). Kazuo Ishiguro wrote about world politics in *The Remains of the Day* (1989). Ireland produced gritty novels about lower-class urban characters, such as *Paddy Clarke, Ha Ha Ha* (1993) by Roddy Doyle.

Several African American and Asian American women writers created important novels that explored aspects of the modern black and Asian experience. These authors included Toni Cade Bambara in *The Salt Eaters* (1980), Bette Bao Lord in *Spring Moon* (1981), Alice Walker in *The Color Purple* (1982), Toni Morrison in *Beloved* (1987), and Amy Tan in *The Joy Luck Club* (1989).

The novel today continues to explore national themes. Examples include *American Pastoral* by Philip Roth, *Mason & Dixon* by Thomas Pynchon, and *Underworld* by Don DeLillo (all of the United States, all published in 1997), and *The God of Small Things* (1997) by Arundhati Roy of India. Michael Seidel

November is the 11th month of the year according to the Gregorian calendar, which is used in almost all the world today. It takes its name from *novem,* the Latin word for *nine.* In the early Roman calendar, November was the ninth month. Because July was named for Julius Caesar and August for Augustus Caesar, the Roman Senate offered to name the 11th month for Tiberius Caesar. He refused modestly, saying, "What will you do if you have 13 emperors?" Originally there were 30 days in November, then 29, then 31. From the time of Augustus, the month has had 30 days.

November is a month of remembrance. On Día de los muertos, November 2, Mexicans honor the dead. This holiday is somber, yet has many playful characteristics as well. On November 11, Americans honor war veterans with a national holiday called Veterans Day. In Canada, the holiday is called Remembrance Day. This holiday, also known as Armistice Day in some countries, commemorates the signing of the *armistice* (temporary peace agreement) that ended World War I (1914-1918).

On the second Sunday of the month, Father's Day is celebrated in Sweden. Children's Book Week is observed in November in many places. November 14 is Children's Day in India. The Japanese festival Shichi-Go-San (Three-Five-Seven) is a special day set aside for children who are 3, 5, or 7 years old. It is held on November 15. Election Day in the United States falls on the first Tuesday after the first Monday of the month.

People in the United States celebrate Thanksgiving Day on the fourth Thursday of November. On Guy Fawkes Day, November 5, people in the United Kingdom recall the Gunpowder Plot of 1605, an unsuccess-

Important November events

1 All Saints' Day observed by Christians.
— Benvenuto Cellini, Italian goldsmith, born 1500.
— Crawford W. Long, American physician who first used ether as an anesthetic in surgery, born 1815.

2 All Souls' Day observed by Christians.
— Daniel Boone, American frontiersman, born 1734.
— Marie Antoinette, French queen, born 1755.
— Spanish expedition led by Gaspar de Portolá reached San Francisco Bay, 1769.
— James K. Polk, 11th U.S. president, born 1795.
— Warren G. Harding, 29th U.S. president, born 1865.
— North Dakota became the 39th U.S. state, 1889.
— South Dakota became the 40th U.S. state, 1889.

3 Stephen Austin, colonizer of Texas, born 1793.
— Vilhjalmur Stefansson, Canadian explorer, born 1879.
— Panama declared its independence from Colombia, 1903.

4 Erie Canal formally opened at New York, 1825.
— Will Rogers, American humorist, born 1879.
— Iranian revolutionaries took over U.S. Embassy in Tehran and seized some U.S. citizens as hostages, 1979.
— Yitzhak Rabin, prime minister of Israel, assassinated 1995.

5 Guy Fawkes Day in the United Kingdom marks failed Gunpowder Plot to blow up Houses of Parliament, 1605.
— Eugene V. Debs, American labor leader, born 1855.
— Will Durant, American historian, born 1885.

6 John Philip Sousa, American bandmaster, born 1854.
— Ignace Jan Paderewski, Polish pianist, composer, and statesman, born 1860.
— First U.S. intercollegiate football game, Rutgers versus College of New Jersey (Princeton), at Rutgers, 1869.

7 General William Henry Harrison defeated Indians in Battle of Tippecanoe, 1811.
— Marie Curie, French physicist, born 1867.
— Albert Camus, French author, born 1913.
— Bolsheviks ousted provisional Russian government, 1917. (October 25 on the Russian calendar then in use.)

8 Edmond Halley, British astronomer, born 1656.
— Mount Holyoke Female Seminary (today Mount Holyoke College) opened, 1837.
— Montana became the 41st U.S. state, 1889.

9 Ivan Turgenev, Russian novelist, born 1818.
— Edward VII of the United Kingdom born 1841.
— Kaiser Wilhelm II abdicated German throne, 1918.
— *Kristallnacht,* when Jewish businesses and synagogues throughout Germany were attacked by the Nazis, 1938.
— Cambodia became independent in 1953.
— Opening of the Berlin Wall, Germany, 1989.

10 Martin Luther, German religious leader, born 1483.
— William Hogarth, English painter, born 1697.
— Friedrich Schiller, German playwright and poet, born 1759.
— Sir John S. D. Thompson, Canadian prime minister, born 1844.
— Donald MacMillan, American Arctic explorer, born 1874.

11 Remembrance Day, Canada.
— Fyodor M. Dostoevsky, Russian novelist, born 1821.
— Ned Kelly, Australian bushranger, hanged 1880.
— Washington became the 42nd U.S. state, 1889.
— Poland was proclaimed an independent republic in 1918.
— Armistice signed ending World War I, 1918.
— Veterans Day first celebrated in United States, 1954.

12 Joseph Hopkinson, American jurist, born 1770.
— Elizabeth Cady Stanton, American reformer, born 1815.
— Bahá'u'lláh, Baháí prophet, born 1817.
— Auguste Rodin, French sculptor, born 1840.

13 James Clerk Maxwell, Scottish physicist, born 1831.
— Robert Louis Stevenson, Scottish novelist, born 1850.
— Louis D. Brandeis, American jurist, born 1856.
— Holland Tunnel opened in New York City, 1927.

14 Robert Fulton, American inventor, born 1765.
— Claude Monet, French painter, born 1840.

Nov. 4—Will Rogers born

Nov. 6—first intercollegiate football game

ful attempt to blow up the Houses of Parliament. The day is marked with fireworks and bonfires. In Thailand, Loy Krathong, a water festival, is held in mid-November.

Religious holidays in November include the Christian All Saints' Day on November 1. The Bahá'í observance of the birth of Bahá'u'lláh, who founded the faith, occurs on the 12th. Sikhs commemorate the birth of Nanak, the first Sikh *guru* (spiritual teacher), in November.

November's flower is the chrysanthemum. The topaz is November's birthstone. Carole S. Angell

Quotations

November woods are bare and still;
November days are clear and bright;
Each noon burns up the morning's chill,
The morning's snow is gone by night.
Helen Hunt Jackson

November's sky is chill and drear,
November's leaf is red and sear.
Sir Walter Scott

Autumn wins you best by this, its mute
Appeal to sympathy for its decay.
Robert Browning

The wild November comes at last
Beneath a veil of rain;
The night wind blows its folds aside,
Her face is full of pain.
Richard Henry Stoddard

Novi Sad, *NAW vee SAHD* (pop. 179,626), is a Yugoslav center of manufacturing and transportation. The city lies in Serbia, about 45 miles (72 kilometers) northwest of Belgrade. For location, see **Serbia** (map). The Danube River meets the Mali Bački Canal at Novi Sad. The canal is part of a system of waterways that links the Danube and Tisa rivers. Novi Sad also lies on the main highway and railroad between Belgrade and Budapest, Hungary. The city produces electrochemical equipment and processed foods. It is the home of the University of Novi Sad.

Novi Sad was founded in the early 1690's as the headquarters of the Serbian Orthodox Church. It grew as a trade center for the nearby farm area. A boom began in Novi Sad during the 1960's after petroleum and natural gas were found near the city. Sabrina P. Ramet

Novocain. See **Procaine.**

Novosibirsk, *NAW vah sih BEERSK* (pop. 1,402,100), is an important center of manufacturing in Russia. The city lies on the Ob River, about 1,700 miles (2,740 kilometers) east of Moscow, in Siberia. Novosibirsk is the largest city in Siberia (see **Russia** [political map]).

Many factories in Novosibirsk manufacture heavy equipment, including farm and mining machinery and diesel trucks. The city also produces steel. Airlines, railroads, and riverboats serve Novosibirsk.

Novosibirsk was founded in 1893 as a settlement for workers building a railroad across Siberia. The city grew as a transportation center. Industry boomed during World War II (1939-1945), when many factories in combat areas in western areas of the country were moved to the safety of Novosibirsk. In 1958, the government built Akademgorodok (Academy City), a suburb of Novosibirsk, as a science research center. Craig ZumBrunnen

Noyce, Robert (1927-1990), is one of the two inventors of the microchip, or *integrated circuit.* Such a chip contains all the components of an electronic circuit. Microchips are widely used in computers and other types of electronic equipment.

Noyce made his chip in 1959 while working at Fairchild Semiconductor Corporation, a company he helped found. Jack Kilby, an electrical engineer, developed a similar chip at about the same time, but working independently. Kilby's patent was filed first. But Noyce's design made the connections between components a part of the manufacturing process, while Kilby's did not.

In 1968, Noyce left Fairchild. He and Gordon Moore, a research scientist from Fairchild, founded Intel Corporation, now a leading manufacturer of semiconductor chips.

Robert Norton Noyce was born on Dec. 12, 1927, in Burlington, Iowa. He graduated from Grinnell College in 1949 and earned a doctorate in physics from Massachusetts Institute of Technology in 1953. Paul N. Edwards

Noyes, *noyz,* **Alfred** (1880-1958), was one of the most popular English poets of the early 1900's. He became famous for his ballads and lyric poems about English history. Many of Noyes's poems also show his love of the sea. His reputation has declined since the mid-1900's, but some of his poetry remains popular with children, especially the exciting ballad "The Highwayman" (1906).

Noyes was born on Sept. 16, 1880, in Wolverhampton. He established himself as a leading poet with the epic *Drake* (1906-1908). *Drake* deals with the famous English sea captain Sir Francis Drake. In *The Golden Hynde* (1908), Noyes filled his poems with colorful images of the sea and sea voyages. *Tales of the Mermaid Tavern* (1913) describes the adventures of noted Englishmen who lived during the reign of Queen Elizabeth I.

Noyes's most ambitious work was perhaps *The Torch-bearers,* a long three-part poem. It honors the contributions of the great scientists of history. The poem consists of *The Watchers of the Sky* (1922), *The Book of Earth* (1925), and *The Last Voyage* (1930).

In 1927, Noyes converted to Roman Catholicism. His conversion influenced many of his later writings. In *The Unknown God* (1934), he wrote a prose account of his change from an unbeliever to a devout Christian.

In addition to verse, Noyes wrote biographies, literary criticism, novels, plays, and short stories. Some of his literary essays were collected in *Pageant of Letters* (1940). Noyes also wrote an autobiography, *Two Worlds from Memory* (1953). Garrett Stewart

Nubia, *NOO bee uh,* was a region of ancient Africa. It covered part of what is now Sudan. Nubia extended along the Nile River from the southern boundary of ancient Egypt almost to present-day Khartoum, Sudan.

The earliest Nubians were probably blacks. The Nubians were controlled by Egyptian rulers at times from about 2000 to 1000 B.C. The Egyptians regarded Nubia as a source of gold and as a trading center for cattle, ivory, and slaves from central Africa. Nubia's association with Egypt greatly influenced Nubian art and religion.

WORLD BOOK map

The ancient region of Nubia, shown in yellow, occupied an area along the Nile River in what is now Sudan.

Kush, the most important civilization of Nubia, developed rapidly after 1000 B.C. This Nubian kingdom, which lasted until about A.D. 350, became a center of ironworking, learning, and trade. Kushites ruled Egypt from about 750 to 670 B.C. See **Kush.**

During the A.D. 500's, the people of Nubia were converted to Christianity. A large part of Nubia remained Christian until the 1300's, when Arab invaders conquered the region. They firmly established Islam, the religion of the Muslims. John Middleton

Nuclear bomb. See **Nuclear weapon.**

Patrick Aventurier, Gamma/Liaison

A nuclear power plant uses the heat of a controlled nuclear reaction to produce steam, which then generates electric energy. The plant shown here, located southeast of Paris on the Seine River, has tall structures called *cooling towers* to dispose of excess heat.

Nuclear energy

Nuclear energy, also called *atomic energy,* is the powerful energy released by changes in the *nucleus* (core) of atoms. The heat and light of the sun result from nuclear energy. Scientists and engineers have found many uses for this energy, including the production of electric power, the explosion of nuclear weapons, and the diagnosis and treatment of medical conditions.

Scientists knew nothing about nuclear energy until the early 1900's, though they knew that all matter consists of atoms. Through further study, scientists learned that a nucleus makes up most of the *mass* (quantity of matter) of every atom and that this nucleus is held together by an extremely strong force. A huge amount of energy is concentrated in the nucleus because of this force. The next step was to make nuclei let go of much of that energy.

Scientists first released nuclear energy on a large scale at the University of Chicago in 1942, three years after World War II began. This achievement led to the development of the atomic bomb. The first atomic bomb was exploded in the desert near Alamogordo, New Mexico, on July 16, 1945. In August, United States airplanes dropped bombs on Hiroshima and Nagasaki, Japan. The bombs largely destroyed both cities and helped end World War II.

The contributor of this article is Mirela Gavrilas, Assistant Professor of Nuclear Engineering at the University of Maryland at College Park.

Since 1945, scientists have developed peaceful uses of nuclear energy. The energy released by nuclei creates large amounts of heat. This heat can be used to make steam, and the steam can be used to drive machines that generate electric power. Engineers have built devices called *nuclear reactors* to produce and control nuclear energy.

A nuclear reactor operates somewhat like a furnace. However, instead of using such fossil fuels as coal or oil, almost all reactors use uranium. And instead of burning in the reactor, the uranium *fissions*—that is, its nuclei split into two or more fragments. As a nucleus splits, it releases energy that is converted largely into heat. The fission of 1 pound of uranium releases more energy than the burning of 3 million pounds (1,500 tons) of coal. Stated in metric terms, the fission of 1 kilogram of uranium releases more energy than the burning of 3 million kilograms (3,000 metric tons, or 3 kilotons) of coal.

One important peaceful use of nuclear energy is the production of electric power Nuclear energy also powers some submarines, surface ships, and spacecraft. Nuclear reactions also produce particles and rays called *nuclear radiation* that have uses in medicine, industry, and science. However, nuclear radiation can be extremely dangerous. Exposure to too much radiation can result in a condition called *radiation sickness* (see **Radiation sickness**).

This article deals mainly with nuclear energy as a source of electric power. To learn about other uses of nuclear energy, see **Nuclear weapon; Ship** (Nuclear power and automation); **Submarine.**

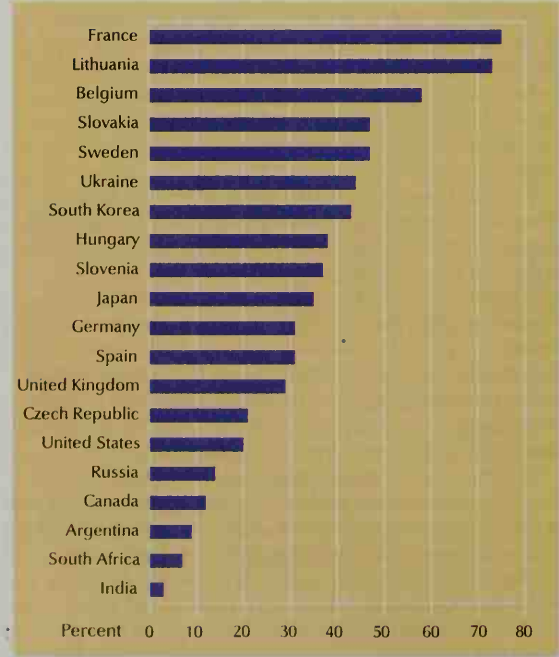
The role of nuclear energy in power production

Almost all the world's electric power is produced by *hydroelectric* and *thermal* power plants. Hydroelectric plants use the force of rushing water from a dam or waterfall to generate electric power. Thermal plants use the force of steam from boiling water. The great majority of thermal plants burn fossil fuels—coal, oil, and natural gas—to produce heat to boil water. The remaining thermal plants fission uranium.

Few countries have enough water power to generate large amounts of hydroelectric power, and many regions have already fully exploited their hydroelectric capacity. Most countries depend mainly on fossil fuels. But fossil fuels are a nonrenewable resource, and burning them produces gases that can damage the environment. Therefore, many experts predict that nuclear power will become increasingly important.

Worldwide use of nuclear energy. Nuclear power reactors produce electric power in more than 30 countries. There are more than 435 reactors worldwide. These reactors produce about 17 percent of the world's electric power. The United States is the world's leading producer of nuclear energy. In addition to these reactors, there are more than 3,000 nuclear facilities worldwide that are used for applications in research, medicine, industry, and agriculture.

Advantages and disadvantages of nuclear energy. Nuclear power plants have two main advantages over fossil-fuel plants. (1) Once built, a nuclear plant can be less expensive to operate than a fossil-fuel plant, mainly because a nuclear plant uses a much smaller volume of fuel. (2) Uranium, unlike fossil fuels, releases no chemical or solid pollutants into the air during use.



However, nuclear power plants have three major disadvantages. These disadvantages have slowed the development of nuclear energy in some countries. (1) Nuclear power plants cost more to build than fossil-fuel plants. (2) Because of the need to assure that hazardous amounts of radioactive materials are not released, nuclear power plants must meet certain government regulations that fossil-fuel plants do not have to meet. For example, a nuclear plant must satisfy the government that it can quickly and automatically deal with any kind of emergency. (3) Used nuclear fuel produces dangerous radiation long after it has been removed from the reactor. As a result, safe disposal of nuclear waste presents a challenge.

The full development of nuclear energy. Many experts believe that the benefits of nuclear energy outweigh any problems involved in its production. According to these experts, oil may be so scarce by the mid-2000's that it will be too expensive to drill. Canada, Germany, Russia, the United States, and some other countries have enough coal to meet their energy requirements for hundreds of years at present rates of use. However, coal releases large amounts of sulfur and other pollutants into the air when it is burned (see **Environmental pollution**). If nuclear energy were fully developed, it could completely replace oil and coal as a source of electric power.

But a number of problems must be solved before nuclear energy can be fully developed. For example, almost all today's power reactors use a scarce type of uranium known as *U-235.* If U-235 continues to be used at

Share of electric power from nuclear energy

This graph shows the percentage of total electric power derived from nuclear energy by selected countries.

Figures are for 1999. Source: International Atomic Energy Agency.

Leading nuclear energy producing countries

Nuclear energy produced in a year	
United States	719,400,000,000 kilowatt-hours
France	375,000,000,000 kilowatt-hours
Japan	306,900,000,000 kilowatt-hours
Germany	160,400,000,000 kilowatt-hours
Russia	110,900,000,000 kilowatt-hours
South Korea	97,800,000,000 kilowatt-hours
United Kingdom	91,200,000,000 kilowatt-hours
Canada	70,400,000,000 kilowatt-hours
Sweden	70,100,000,000 kilowatt-hours
Ukraine	67,400,000,000 kilowatt-hours

Figures are for 1999.

its present rate, the world's supply of it will become so small that it will be too expensive to mine and process by about 2050. Therefore, for nuclear energy to replace other energy sources, it must be based on fuel that is much more plentiful than U-235.

The composition of matter

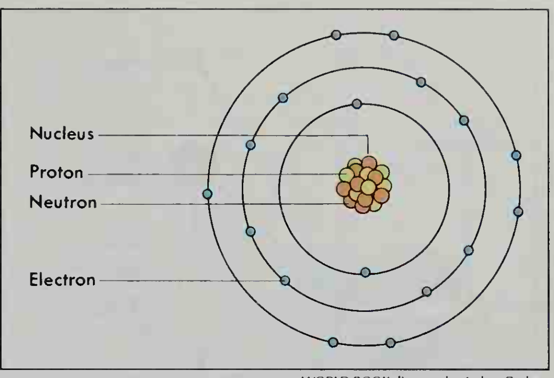
The process by which a nucleus releases energy is called a *nuclear reaction.* To understand the various types of nuclear reactions, a person must know something about the nature of matter.

All the matter that makes up all solids, liquids, and gases is composed of *chemical elements.* The chemical elements, in turn, are composed of atoms. A chemical element consists of a substance that cannot be broken down chemically into simpler substances. There are 115 known chemical elements. Ninety-one of them are found on or in the earth. The other 24 are artificially created. However, one of these 24 elements, plutonium, occurs naturally in tiny amounts.

Scientists rank the elements according to *mass,* a measure of the quantity of matter in an object. An object's mass is proportional to its weight. Hydrogen is the lightest natural element, and uranium is the heaviest. Most of the artificially created elements are heavier than uranium.

Atoms and nuclei. An atom consists of a positively charged nucleus and one or more *electrons,* which are negatively charged particles. The nucleus makes up almost all of an atom's mass. The electrons, which have almost no mass, revolve around the nucleus. Electrons determine the various chemical combinations that an atom enters into with other kinds of atoms (see **Chemistry** [Fundamental ideas of chemistry]). However, electrons do not play an active part in nuclear reactions.

The nuclei of every chemical element except hydrogen consist of particles called *protons* and *neutrons.* An ordinary nucleus of hydrogen, the lightest element, has one proton and no neutrons. The heaviest elements, such as uranium and thorium, have the largest number of protons and neutrons.



Protons carry a positive charge. Neutrons have no net charge. Extremely strong forces, called *nuclear forces,* hold the protons and neutrons together in the nucleus. The nuclear forces of each type of nucleus determine the amount of energy that would be required to release its neutrons and protons.

Isotopes. Most chemical elements have more than one form. These different forms are called the *isotopes* of an element. The atoms that make up each of the different forms have different masses and are also called isotopes.

Scientists identify an isotope by its *mass number*—that is, the total number of protons and neutrons in each of its nuclei. All the isotopes of a given element have the same number of protons in every nucleus. Every hydrogen nucleus, for example, has just 1 proton. Every uranium nucleus has 92 protons.

However, each isotope of an element has a different number of neutrons in its nuclei and so has a different mass number. For example, the most plentiful isotope of uranium has 146 neutrons. Its mass number is therefore 238 (the sum of 92 and 146). Scientists call this isotope *uranium 238* or *U-238.* The uranium isotope that almost all nuclear reactors use as fuel has 143 neutrons, and so its mass number is 235. This isotope is called *uranium 235* or *U-235.*

No two elements have the same number of protons in their atoms. If an atom gains or loses one or more protons, it becomes an atom of a different element. However, if an atom gains or loses one or more neutrons, it be-

WORLD BOOK diagram by Arthur Grebetz

An atom consists of a nucleus and one or more electrons. The nucleus, which makes up almost all of an atom's mass, consists of tiny particles called *protons* and *neutrons.* They are held together by an extremely strong force.

Nuclear energy terms

Atom consists of a positively charged nucleus and one or more negatively charged electrons. The electrons revolve about the nucleus.

Chain reaction is a continuous, self-sustaining series of fission reactions in a mass of uranium or plutonium.

Fission is the type of nuclear reaction that occurs when a nucleus of uranium or another heavy element is split into two nearly equal parts.

Fusion is a type of nuclear reaction that occurs when two lightweight nuclei *fuse* (combine) and form a heavier nucleus. Fusion produces the sun's energy.

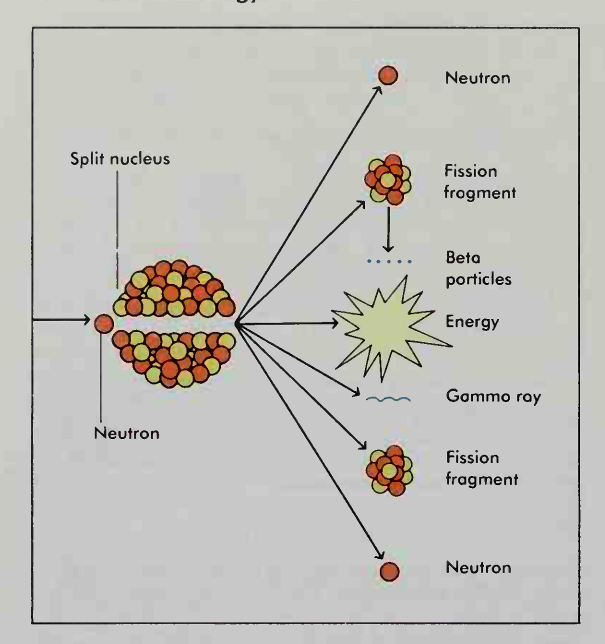
Half-life is the time required for half the atoms of a radioactive substance to decay into another substance.

Isotopes are different forms of the same element. The atoms that make up each of the different forms have different mass numbers. The atoms are also called isotopes.

Mass number is the total number of neutrons and protons in the nucleus of an atom.

Neutron is an electrically *neutral* (uncharged) particle in a nucleus.

Nuclear radiation consists of high-energy particles and tiny packets of energy called *photons* that are given off during a nuclear reaction.



Nuclear reaction involves a change in the structure of a nucleus. Fission, fusion, and radioactive decay are the most important types of nuclear reactions.

Nuclear reactor is a device for producing nuclear energy by means of controlled chain reactions.

Nucleus is the core of an atom and carries a positive charge. The nuclei of all elements except hydrogen consist of neutrons and protons. An ordinary hydrogen nucleus has one proton and no neutrons.

Proton is a positively charged particle in a nucleus.

Radioactive decay, or radioactivity, is the process by which a nucleus *spontaneously* (naturally) changes into the nucleus of another isotope or element. The process releases energy mainly in the form of nuclear radiation.

Nuclear fission is the chief method of producing nuclear energy. It involves using a neutron to split a nucleus of a heavy element, such as uranium, into two *fission fragments.* Besides heat energy, fission releases neutrons and such radiation as gamma rays. The fragments give off beta particles and gamma rays.

Neutron

WORLD BOOK diagrams by Arthur Grebetz

A chain reaction results in the continuous fissioning of nuclei and so produces a steady supply of energy. To produce a chain reaction, each fissioned nucleus must give off neutrons to fission at least two more nuclei, *shown here.* Uranium and plutonium are the materials used to produce a chain reaction.

comes another isotope of the same element.

Nuclear reactions

A nuclear reaction changes the structure of a nucleus. The nucleus gains or loses one or more neutrons or protons. It thus changes into the nucleus of a different isotope or element. If the nucleus changes into the nucleus of a different element, the change is called a *transmutation* (see **Transmutation of elements**).

Three types of nuclear reactions release useful amounts of energy. These reactions are (1) radioactive decay, (2) nuclear fission, and (3) nuclear fusion. During each reaction, the matter involved loses mass. The mass is lost because it changes into energy.

Radioactive decay, or radioactivity, is the process by which a nucleus changes into the nucleus of another isotope or element. The process releases energy chiefly in the form of particles and rays called *nuclear radiation.* Uranium, thorium, and several other elements decay naturally and so contribute to the natural, or *background,* radiation that is always present on the earth. Nuclear reactors produce radioactive isotopes artificially. Nuclear radiation accounts for about 10 percent of the energy produced in a reactor.

Nuclear radiation consists largely of alpha and beta particles and gamma rays. An *alpha particle,* which is made up of two protons and two neutrons, is identical with a helium nucleus. A *beta particle* is identical with an electron. It results from the breakdown of a neutron in a radioactive nucleus. The breakdown also produces a proton, which remains in the nucleus. *Gamma rays* are electromagnetic waves similar to photons or X rays (see **Electromagnetic waves**).

Scientists measure the rate of radioactive decay in units of time called *half-lives.* A half-life equals the time required for half the atoms of a particular radioactive element or isotope to decay. Half-lives range from a fraction of a second to billions of years. See **Isotope** (Radioactive isotopes).

Nuclear fission is the splitting of heavy nuclei to release energy. All commercial nuclear reactors produce energy in this way.

To produce fission, a reactor requires a *bombarding particle,* such as a neutron, and a *target material,* such as U-235. Nuclear fission occurs when the bombarding particle splits a nucleus in the target material into two or more parts called *fission fragments.* Each fragment consists of a nucleus with about half the neutrons and protons of the original nucleus. The energy is released in many forms. But most of the energy released by fission eventually takes the form of heat.

The bombarding particle must first be captured by a nucleus for fission to occur. Reactors use neutrons as bombarding particles because they are the only atomic particles that are both easily captured and able to cause fission. Neutrons can also pass through most kinds of matter, including uranium.

The target material. Commercial power reactors use uranium as their target material, or fuel. Uranium is abundant in nature and has one of the easiest nuclei to split because of its large number of protons. Protons naturally repel one another, and so a nucleus with many protons has a tendency to "fly apart." It can thus be split with little difficulty.

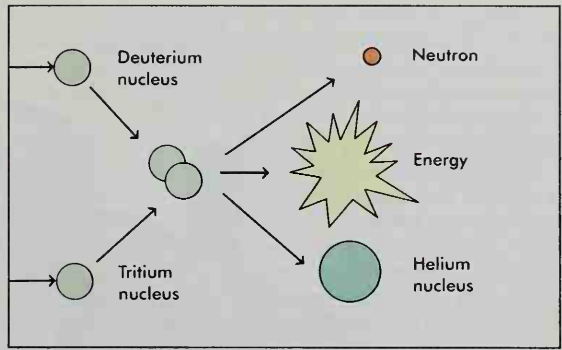
Uranium also makes a good nuclear reactor fuel because it can sustain a continuous series of fission reac-

ons. As a result, uranium can produce a steady supply f energy. To create a series of reactions, each fissioned ucleus gives off neutrons. Each of these neutrons can plit another uranium nucleus, thus releasing still more eutrons. As this process is repeated over and over, it ecomes a self-sustaining *chain reaction.* Chain reacons can produce an enormous amount of energy. Only uclei that have many more neutrons than protons, such s uranium nuclei, can produce a nuclear chain reaction.

The scarce uranium isotope U-235 is the only natural naterial that nuclear reactors can use to produce a hain reaction. Nuclei of the much more abundant U-238 sotope usually absorb neutrons without fissioning. An bsorbed neutron simply becomes part of the U-238 nuleus.

Neutrons released in fission travel too rapidly to be bsorbed by U-235 nuclei in numbers large enough to ustain a chain reaction. Reactors can use U-235 as a fuel ecause they utilize other materials called *moderators* o slow the neutrons down. Some reactors use water as moderator, while others use graphite or *heavy water.* Heavy water contains an isotope of hydrogen called *deuterium* in place of hydrogen. Deuterium is also nown as *heavy hydrogen.*

The slowed neutrons travel at a velocity of about 2.2 ilometers per second and are known as *thermal neurons.* Reactors that use moderators are called *thermal eactors.* Most of today's reactors are thermal reactors.



Thermal neutrons are highly effective in causing fision in U-235. Therefore, the uranium in a thermal reacor can have a low percentage of U-235 content. Depending on their design, today's power reactors use a U-235 content ranging from 0.71 percent—the percentage in natural uranium—to almost 5 percent. Special purpose reactors may use fuel with a higher percentage of U-235.

Scientists have also developed *fast reactors,* in which high-velocity neutrons cause the fissions. These reactors use plutonium or uranium 233 fuel. *Fast breeder reactors* produce more fuel material than they consume. A ast breeder reactor that converts U-238 to plutonium can greatly extend the use of uranium as an energy resource. In addition, a fast reactor can be designed to consume certain radioactive elements that have long ives and are present in used fuel. Such a reactor would reduce the amount of certain radioactive wastes that must be disposed of. The section *Research on new types of reactors* in this article discusses fast reactors in more detail.

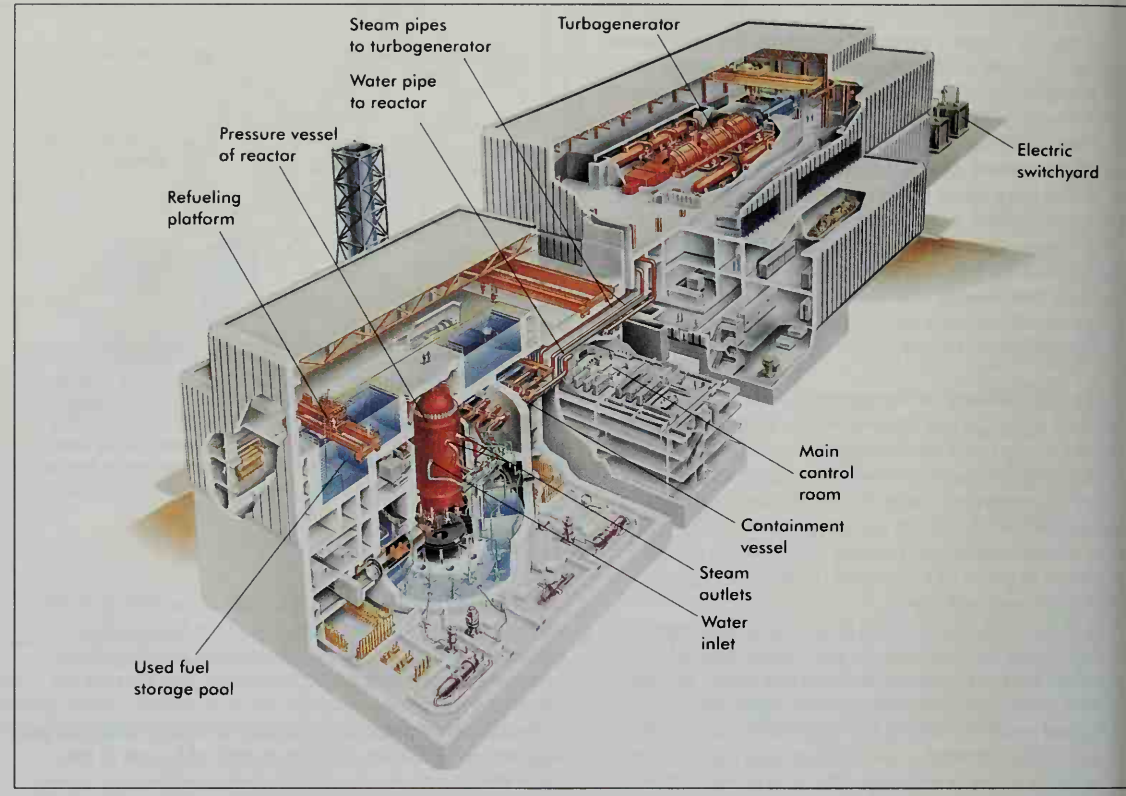
Nuclear fusion occurs when two lightweight nuclei *fuse* (combine) and form a nucleus of a heavier element. The products of the fusion reaction have less mass than the original nuclei had. The lost mass has therefore been changed into energy.

Fusion reactions that produce large amounts of energy can be created by means of extremely intense heat. Such reactions are called *thermonuclear reactions.* Thermonuclear reactions produce the energy of both the sun and the hydrogen bomb.

A thermonuclear reaction can occur only in a form of matter called *plasma.* Plasma is a gaslike substance made up of free electrons and *free nuclei* (nuclei that have no electrons revolving about them). Normally, nuclei repel one another because of the positive charges

WORLD BOOK diagram by Arthur Grebetz

Nuclear fusion occurs when two lightweight nuclei unite and form a heavier nucleus. In the example shown here, nuclei of deuterium and tritium unite and form a helium nucleus. This process releases energy and a neutron. Repeated many times, fusion creates the energy of the sun and the hydrogen bomb. However, scientists have yet to control fusion for energy production.



of their protons. However, if a plasma containing lightweight atomic nuclei is heated many millions of degrees, the nuclei begin moving so fast that they overcome the force of repulsion and fuse. See **Plasma** (in physics).

Problems of controlling fusion. Scientists have not yet succeeded in harnessing the energy of fusion to produce electric power. In their fusion experiments, scientists generally work with plasmas that are made from the three isotopes of hydrogen—protium, deuterium, and tritium. The most common hydrogen isotope, protium, has a nucleus that consists of a single proton. Ordinary hydrogen is made almost entirely of protium. Deuterium is the second most common isotope. It has a nucleus made up of one proton and one neutron. The nucleus of the rarest isotope, *tritium,* consists of one proton and two neutrons. Tritium is not found in nature. Scientists produce tritium artificially by bombarding lithium nuclei with neutrons. Of the three isotopes of hydrogen, only tritium is radioactive.

A mixture of deuterium and tritium is an excellent thermonuclear fuel because ordinary seawater contains plentiful stocks of deuterium and lithium. One barrel of seawater contains enough of these substances to produce as much energy as the burning of about one-fifth of a barrel of oil.

To produce a controlled thermonuclear reaction, a plasma of one or more hydrogen isotopes must be heated many millions of degrees. But scientists have yet to develop a container that can hold plasma this hot. The plasma expands quickly. In addition, the walls of the container must be kept at low temperatures to prevent them from melting. But if the plasma touches the walls, it becomes too cool to produce fusion. The plasma must therefore be kept away from the walls of the container long enough for its nuclei to fuse and produce usable amounts of energy.

Fusion devices. Most experimental fusion reactors are designed to contain hot plasma in "magnetic bottles" twisted into various shapes. The walls of the bottles are made of copper or some other metal and are surround-

GE Nuclear Energy

A nuclear power plant uses a nuclear reactor to convert water to steam. The steam drives turbogenerators that produce electric energy. This energy flows through wires to a switchyard, where other wires carry it from the plant. This plant uses a *boiling water reactor,* which produces steam inside its pressure vessel. After the steam drives the turbogenerators, it is cooled so that it turns back into water. This water is recirculated into the reactor. A steel and concrete containment vessel guards against the escape of radioactive material from an accidental leak in the reactor.

ed by electromagnets. An electric current is passed through the electromagnets, creating a magnetic field on the inside of the walls. The magnetism pushes the plasma away from the walls. All the fusion devices thus far developed, however, use much more energy than they create. The section *Research on new types of reactors* discusses experimental fusion reactors in greater detail.

How nuclear energy is produced

All large commercial nuclear power plants produce energy by fissioning U-235. But U-235 makes up about 0.71 percent of the uranium found in nature. About 99.28 percent of all natural uranium is U-238. The two types occur together in uranium ores, such as *carnotite* and *pitchblende.* Separating the U-235 from the U-238 in these ores is difficult and costly. For this reason, the fuel used in reactors consists largely of U-238. But the fuel has enough U-235 to produce a chain reaction. Nuclear fuel requires special processing before and after it is used. The processing begins with the mining of uranium ore and ends with the disposal of fuel wastes.

This section deals chiefly with the methods used in the U.S. nuclear power industry. These methods resemble those used in other countries.

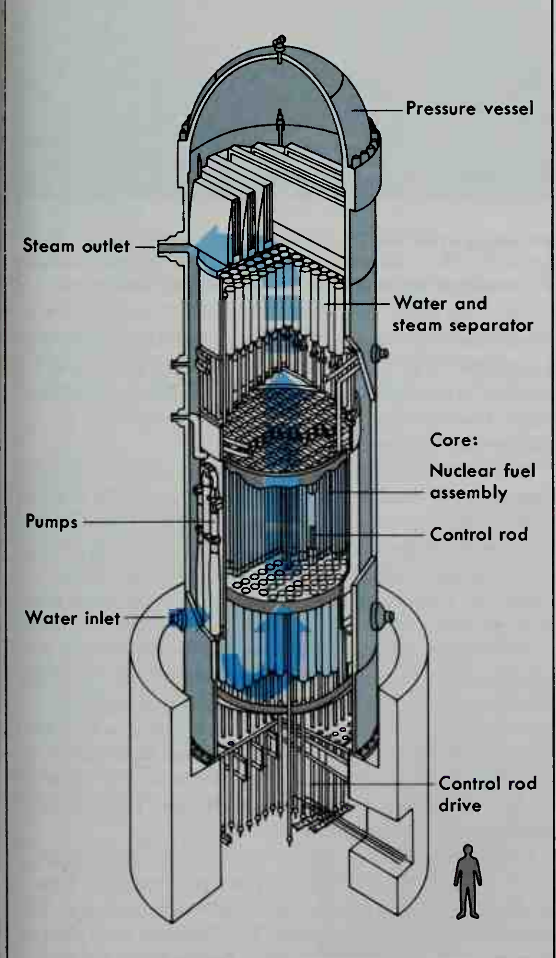
Power plant design. Most nuclear power plants cover an area of 200 to 300 acres (80 to 120 hectares). The majority are built near a large river or lake because nuclear plants require enormous quantities of water for cooling purposes.

A nuclear plant consists of several main buildings, one of which houses the reactor and its related parts. Another main building houses the plant's turbines and electric generators. Every plant also has facilities for storing unused and used fuel. Many plants are largely automated. Each of these plants has a main control room, which may be in a separate building or in one of the main buildings.

The reactor building, or *containment building,* has a thick concrete floor and thick walls of steel or of concrete lined with steel. The concrete and steel guard against the escape of radioactive material from an accidental leak in the nuclear reactor.

Power reactors that are used in nuclear power plants in the United States consist of three main parts: (1) a reactor vessel, also called a pressure vessel; (2) a core; and (3) a set of control rods. In addition, reactor operations depend upon two substances—moderators and coolants.

The *reactor vessel* is a tanklike structure that encloses

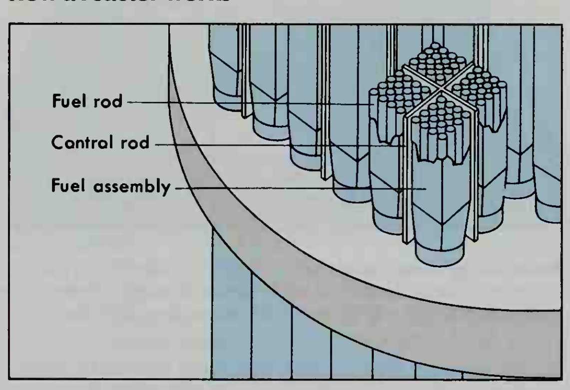


the other main parts of the reactor. The vessel has steel walls that are typically at least 6 inches (15 centimeters) thick and capable of containing the high pressure exerted in a reactor.

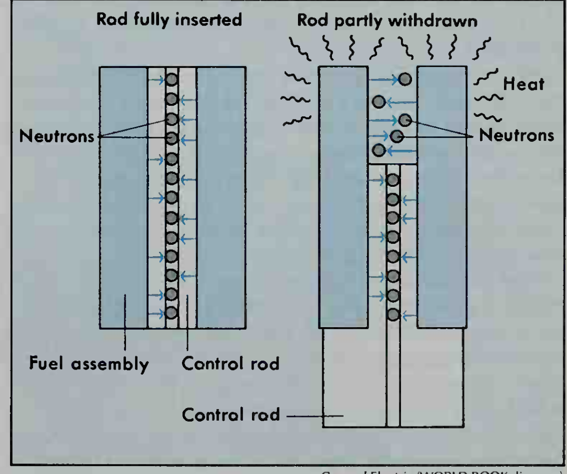
The *core* contains the nuclear fuel, in which the fission chain reaction occurs. The core sits in the lower half of the reactor vessel. A great many *fuel assemblies* stand upright in the core between an upper and lower support plate. Each fuel assembly contains a bundle of *fuel rods.* A fuel rod consists of pellets of fuel inside a metal tube. The pellet material is usually a powder called *uranium dioxide.* The tubing material is typically *zircalloy,* a mixture of the metal zirconium and one or more other metals. Neutrons can pass from the fuel through the tube walls, but most other nuclear particles cannot.

The *control rods* are long metal rods that are used to regulate fission in the fuel. The control rods contain such neutron-absorbing materials as boron, cadmium, hafnium, or silver. A mechanism outside the reactor vessel is attached to the rods. This mechanism inserts the rods into the core and withdraws them when necessary. When inserted fully into the core, the control rods absorb many neutrons and so prevent a fission chain reaction from occurring. To begin operation of the reactor, the control rods are partially withdrawn until a chain reaction occurs at a constant rate. To increase power in the reactor, the rods are withdrawn slightly more. Thus, fewer neutrons are absorbed, and more are available to cause fission. To stop the chain reaction, the rods are inserted all the way into the core to absorb most of the neutrons.

The *moderator* is a substance that slows down neutrons as they pass through it. Slow neutrons are needed for fission in a nuclear reactor. The moderator fills the space between the fuel rods in the fuel assemblies. It



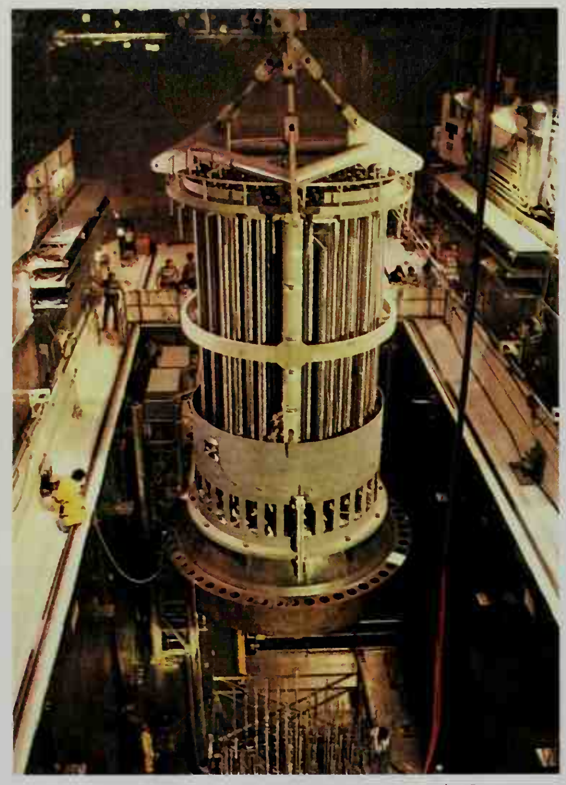
Parts of a nuclear reactor



General Electric (WORLD BOOK diagrams)

The core is the heart of a nuclear reactor. Nuclear fuel in the core of this boiling water reactor produces heat that converts water to steam. The steam runs machinery outside the reactor. A pressure vessel encloses the core and various other equipment.

How a reactor works



Fuel assemblies in the reactor's core hold individual fuel rods that contain atoms of nuclear fuel. As the fuel nuclei split, they produce energy and release neutrons. Other fuel nuclei split when struck by the neutrons, and thus the reaction continues.

General Electric (WORLD BOOK diagram)

Control rods limit the number of fuel nuclei that can split. Materials in the rods absorb neutrons. When fully inserted in the core, the rods absorb so many neutrons that few nuclei can split. To start the reactor, some rods are partly withdrawn.

slows down neutrons as they pass from one fuel rod to another.

The *coolant* is a liquid or gas that carries off the heat created by the fission chain reaction. The coolant circulates throughout the core. It carries the heat from the reactor to an energy conversion system. Thus, the coolant keeps the fuel and cladding from getting too hot, and it transfers energy to a place where electric power can be generated.

All commercial power reactors in the United States are *light water reactors.* In these devices, *light* (ordinary) water serves as the moderator and the coolant. Canadian reactors are *heavy water reactors.* They use *heavy water* as the moderator and the coolant. Heavy water contains deuterium in place of ordinary hydrogen. For more information on reactors, see the section *Research on new types of reactors* in this article.

Fuel preparation. After uranium ore has been mined, it goes through a long milling and refining process to separate the uranium from other elements in the ore. Light water absorbs more neutrons than do other types of moderators. The uranium used in light water reactors must therefore be *enriched*—that is, the percentage of U-235 must be increased. Neutrons then have a better chance of striking a U-235 nucleus. In the United States, uranium that has been separated from the ore is sent to an *enrichment plant.*

Enrichment plants increase the proportion of U-235 in the uranium, depending on the intended use of the uranium. Most light water reactors use fuel with about 2 to 4 percent U-235. Much higher amounts of U-235 are needed in nuclear weapons and in the fuel for nuclear ships. The enriched uranium used as reactor fuel is shipped to *fuel fabrication plants.*

A fuel fabrication plant changes enriched uranium into uranium dioxide. The plant then shapes the uranium dioxide powder into pellets about $\frac{1}{3}$ inch (8 millimeters) in diameter and $\frac{1}{2}$ inch (13 millimeters) long. The pellets are inserted into tubes made of zircalloy. Each tube measures about $\frac{1}{2}$ inch (13 millimeters) in diameter and 10 to 14 feet (3 to 5 meters) long.

After a tube has been filled with uranium dioxide pellets, its ends are welded shut. This sealed tube is called *cladding.* These fuel rods are then fastened together into bundles of 30 to 300 each. Each bundle, or *fuel assembly,* weighs 300 to 1,500 pounds (140 to 680 kilograms). Commercial power reactors need 50 to 150 tons (45 to 136 metric tons) of uranium dioxide. The amount depends on the size of the reactor.

Chain reactions. A reactor requires a certain minimum amount of fuel to keep up a chain reaction. This amount, called the *critical mass,* varies according to the design and size of the reactor. Reactors are designed to hold more than a critical mass of fuel to allow for fuel use during operation. The position of the control rods determines the *effective mass* of the fuel, the amount of fuel taking part in the chain reaction. If the effective mass is decreased below the critical mass, the chain re-

ction will die out and reactor power will decrease. If ne effective mass is increased above the critical mass, ne chain reaction will become more rapid and reactor ower will increase. In an emergency, if the chain reacon became too rapid, the reactor could overheat. Howver, the control rods are available to slow down the hain reaction if it becomes too rapid.

To prepare a reactor for operation, the fuel assemlies are loaded into the core with the control rods ompletely inserted. In a light water reactor, the water sed as a moderator to slow down the neutrons fills the paces between the fuel assemblies. The control rods re then slowly withdrawn, and a chain reaction begins. he farther the rods are withdrawn, the greater the rate f the reaction because fewer neutrons are absorbed. Aore neutrons thus are available to cause fission. When ne desired power is reached, the control rods are posioned so that the effective mass is equal to the critical nass. The water in the core carries off the heat created y the chain reaction. To stop the reaction, the rods are gain inserted all the way into the core to absorb most eutrons.

Steam production. The light water reactors used by lmost all U.S. nuclear plants are of two main types. One ype, the *pressurized water reactor,* produces steam outide the reactor vessel. The other type, the *boiling water eactor,* makes steam inside the vessel.

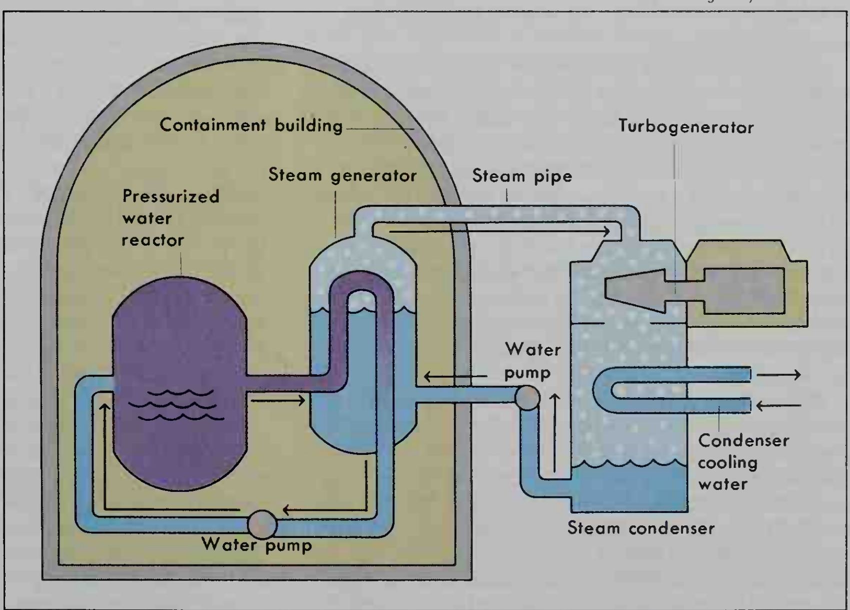
Most nuclear plants in the United States use pressurzed water reactors. These reactors heat the moderator vater in the core under extremely high pressure. The ressure allows the water to heat past its normal boiling oint of 212 °F (100 °C) without actually boiling. The hain reaction heats the water to about 600 °F (315 °C). ipes carry this extremely hot, though not boiling, water o *steam generators* outside the reactor. These generaors transfer heat from the pressurized water to a sepaate supply of water that boils and so produces steam.

In a boiling water reactor, the chain reaction boils the moderator water in the core. Steam is therefore produced inside the reactor vessel. Pipes carry the steam from the reactor to the plant's turbines.

In producing electric energy, a nuclear plant's steam turbines and electric generators work like those in a fossil-fuel plant. The steam produced by a reactor spins the blades of the plant's turbines, which drive the generators. Many plants have combination turbines and generators called *turbogenerators.*

After steam has passed through a plant's turbines, it is piped to a *condenser.* The condenser changes the steam back into water. A reactor can thus use the same water over and over. But a condenser requires a constant supply of fresh water to cool the steam. Most plants pump this water from a nearby river or lake. The water, which becomes warm as it passes through the condenser, is then pumped back into the river or lake. This warm wastewater may heat the water in the river or lake enough to endanger plants and animals that live there. For this reason, the discharge of the wastewater is sometimes called *thermal pollution.*

To help solve the problem of thermal pollution, most new nuclear plants have *cooling towers.* Hot water from the steam condensers is moved through the towers in such a way that the heat passes into the atmosphere. The cooled water is returned to the steam condenser for reuse.



Hazards and safeguards. An ordinary power reactor cannot explode like an atomic bomb. Only a greatly *supercritical* mass of plutonium 239 or of highly enriched uranium 235 can explode in this way. A supercritical mass contains more than the amount of plutonium or uranium required to sustain a chain reaction.

The chief hazards of nuclear power production result from the great quantities of radioactive material that a reactor produces. These materials give off radiation in the form of alpha and beta particles and gamma rays. The reactor vessel is surrounded by thick concrete

The main control room of a nuclear power plant contains a variety of computers, switches, recorders, and other devices. Some of these devices help regulate the production of nuclear energy. Others monitor the plant's safety systems.

blocks called a *shield,* which normally prevents almost all radiation from escaping.

Federal regulations limit the amount of radiation allowed from U.S. nuclear plants. Every plant has instruments that continually measure the radioactivity in and around the plant. They automatically set off an alarm if the radioactivity rises above a predetermined level. If necessary, the reactor is shut down.

A plant's routine safety measures greatly reduce the possibility of a serious accident. Nevertheless, every plant has emergency safety systems. Possible emergencies range from a break in a reactor water pipe to a leak of radiation from the reactor vessel. Any such emergency automatically activates a system that instantly shuts down the reactor, a process called *scramming.* The usual method of scramming is to insert the control rods rapidly into the core.

A leak or break in a reactor water pipe could have dangerous consequences if it results in a loss of coolant. Even after a reactor has been shut down, the radioactive materials remaining in the reactor core can become so hot without sufficient coolant that the core melts. This condition, called a *meltdown,* could result in the release of dangerous amounts of radiation. In most cases, the large containment structure that houses a reactor would prevent radioactive material from escaping into the atmosphere. To prevent such an accident from occurring, all reactors are equipped with an *emergency core cooling system,* which automatically floods the core with water in case of a loss of coolant.

Wastes and waste disposal. The fissioning of U-235 produces more neutrons than are needed to continue a chain reaction. Some of them combine with U-238 nuclei, which far outnumber U-235 nuclei in the reactor fuel. When U-238 captures a neutron, it is changed into U-239. The U-239 then decays into neptunium 239 (Np-239), which decays into plutonium 239 (Pu-239). This same process forms Pu-239 in a breeder reactor. Slow neutrons can fission Pu-239, as well as U-235. Some of the newly formed Pu-239 is thus fissioned during the fissioning of U-235. The rest of the Pu-239 remains in the fuel assemblies.

The fissioning of U-235 also produces many other radioactive isotopes, such as strontium 90, cesium 137, and barium 140. Fuel wastes can remain dangerously radioactive for about 600 years because of the strontium and cesium isotopes. After that time, enough of the strontium and cesium will have decayed into stable isotopes so that they no longer present a severe problem. However, the plutonium and other artificially created elements in the wastes remain radioactive for thousands of years. Even in small amounts, plutonium can cause cancer or genetic damage in human beings. Larger amounts can cause radiation sickness and death (see **Radiation sickness**). Safe disposal of these wastes is one of the most difficult problems involved in nuclear power.

Most nuclear plants need to replace their fuel assemblies only about once a year. The radioactive wastes generate heat, and so used fuel assemblies must be cooled after removal from a reactor. Nuclear plants cool the assemblies by storing them underwater in specially designed *storage pools.*

In the United States, the federal government is working on guidelines for the safe and permanent disposal of nuclear wastes. The current U.S. plan calls for isolating long-lived radioactive waste from the environment in underground storage sites. A law passed by Congress in 1982 required the federal government to build two sites for nuclear wastes from commercial power plants. In 1987, the law was changed to require a single site.

A storage site for nuclear waste must lie in a highly stable area that is free of earthquakes, faulting, and other geologic activity. The site must be dry so that the waste containers cannot be corroded and water supplies cannot be contaminated. The site also must be constructed so that future generations do not dig into it and release radioactivity. The government has for several years been studying the suitability of a location in

levada. In the meantime, commercial nuclear power lants in the United States continue to store used fuel ssemblies and other wastes in pools of water on the lant grounds.

Other countries, including Japan, Russia, and the Jnited Kingdom, are pursuing a *reprocessing* plan. Uner this plan, nuclear plants would ship their used fuel ssemblies to the reprocessing plants for removal of Pu 39 and unused U-235. These radioactive isotopes vould then be recycled into fuel for nuclear reactors. lowever, this method would leave radioactive isotopes 1 the chemical solutions used for reprocessing. These olutions would have to be changed into a solid form ıat could be safely stored.

The nuclear energy industry

In every country that has a nuclear energy industry, ıe government plays a role in the industry. But the govrnment's role varies greatly among countries. This secon deals mainly with the U.S. and Canadian nuclear enrgy industries.

Organization of the industry. Private utility compaies own most of the nuclear power plants in the United tates. The rest are publicly owned. Private companies lso manufacture reactors, mine uranium, and handle ıost other aspects of U.S. nuclear power production.

Canada's nuclear power plants are all publicly owned. tomic Energy of Canada Limited (AECL), a government orporation, has overall responsibility for the country's uclear research and development program. AECL also lesigns the CANDU (*CAN*ada *D*euterium oxide-*U*ranium) eavy water reactors used by all Canadian nuclear lants. Private companies make the various reactor parts nd mine and process the country's uranium. Canada as no uranium enrichment plants because CANDU rectors operate with unenriched uranium fuel.

The industry and the economy. The main economic dvantage of nuclear power plants is that this fuel is less xpensive than fossil fuels. But nuclear plants cost somevhat more to build than do fossil-fuel plants.

Under normal economic conditions, a nuclear plant's avings in fuel eventually make up for its higher contruction expenses. At first, these expenses add to the ost of producing electric power. But after some years, a lant will have paid off its construction costs. It can then roduce electric power more cheaply than a fossil-fuel lant can.

The industry and the environment. Unlike fossiluel plants, nuclear plants do not release solid or chemial pollutants into the atmosphere. For this reason, nulear power is expected to play a major role in enabling everal countries to meet the objectives of the Kyoto 'rotocol, a 1997 agreement calling for reduced emisions of various heat-trapping gases. However, a nuclear lant releases small amounts of radioactive gas into the ir. In addition, the cooling water used in pressurized vater plants picks up a small amount of radioactive tritım in the steam condenser. The tritium remains in this vater when it is returned to a river or lake. But these mall amounts of radiation released into the environıent are not believed to be harmful. Thermal pollution emains a problem at some nuclear plants. But cooling owers help correct this problem.

In a small number of nuclear accidents, hazardous amounts of radiation have been released into the atmosphere. Accidental releases of radioactive substances have occurred in Russia, the United States, and the United Kingdom; and an especially serious accident occurred in 1986 at the Chernobyl nuclear power plant in Ukraine (then part of the Soviet Union). The subsection *Hazards and safeguards* that appears earlier in this article discusses the main methods of guarding against accidents.

Critics of nuclear power also fear another danger to the environment. As power production increases, the creation of high-level radioactive wastes also increases. The problem of storing radioactive wastes is discussed in the subsection *Wastes and waste disposal.*

Government regulation. The Nuclear Regulatory Commission (NRC), an agency of the federal government, regulates nonmilitary nuclear power production in the United States. One of the NRC's main duties is to ensure that nuclear power plants operate safely, and it makes and enforces a variety of safety standards. Every nuclear reactor and power plant must be inspected and licensed by the NRC before it may begin operations. The NRC also supervises the manufacture and distribution of nuclear fuels, and controls the disposal of radioactive wastes from commercial production.

The Atomic Energy Control Board, a Canadian government agency, regulates Canada's nuclear energy industry. The board's duties resemble those of the Nuclear Regulatory Commission.

Careers in nuclear energy cover a wide range of occupations and require widely varying amounts of training. A high percentage of the jobs require a college degree or extensive technical education. Many of these jobs are in large research laboratories, which work to improve nuclear processes and to lessen their hazards. Other careers requiring advanced training are in such areas as uranium mining and processing, reactor manufacturing and inspection, power plant operation, and government regulation.

Many colleges and universities offer undergraduate and graduate degrees in such highly specialized fields as nuclear engineering, nuclear physics, and nuclear technology. The industry also employs many workers with college degrees in various branches of engineering and in such fields as biology, chemistry, geology, and medicine. Many vocational and technical schools and some high schools prepare students for specialized jobs in the industry.

The development of nuclear energy

In 1972, scientists discovered that a natural chain reaction had released nuclear energy nearly 2 billion years ago in a uranium deposit in west-central Africa. Two billion years ago, there had been so little radioactive decay that the ore contained enough U-235 for a chain reaction. An accumulation of ground water acted as a moderator to begin the reaction. As heat from the reaction changed the water into steam, less and less water was available to serve as a moderator and the reaction died out. Except for such rare natural occurrences, nuclear energy was not released on a large scale on the earth until 1942. That year, scientists produced the first artificially created chain reaction. Scientific discoveries that have taken place since the late 1800's have led to the

large-scale release of nuclear energy.

Early developments. Before the late 1800's, scientists did not suspect that atoms could release nuclear energy. Then in 1896, the French physicist Antoine Henri Becquerel found that uranium constantly gives off energy in the form of invisible rays. He thus became the discoverer of radioactivity. Other scientists soon began experiments to learn more about this mysterious phenomenon.

The beginning of nuclear physics. In 1898, the great New Zealand-born physicist Ernest Rutherford identified two kinds of radioactive "rays," which he called *alpha rays* and *beta rays.* He and other researchers later showed that these rays are actually high-energy particles, which became known as *alpha* and *beta* particles. Experiments with these particles then led Rutherford to discover the atom's nucleus. This achievement, which Rutherford announced in 1911, marked the beginning of a new science—nuclear physics.

About 1914, scientists began doing experiments to see what happens when nuclear particles collide. The scientists used alpha particles from naturally radioactive materials to bombard the nuclei of light atoms. Light nuclei do not repel positively charged particles, such as alpha particles, as strongly as heavy nuclei do. Rutherford used this method to produce the first artificial transmutations in a series of experiments from 1917 to 1919. He bombarded nitrogen atoms with alpha particles. In rare collisions, a nitrogen 14 nucleus absorbed an alpha particle (a helium 4 nucleus). At the same time, the alpha particle pushed a proton out of the nitrogen nucleus. The nucleus thereby became an oxygen 17 nucleus.

Artificial fission. To produce nuclear reactions in heavy nuclei, scientists needed a particle that heavy nuclei would not repel. In 1932, the British physicist James Chadwick discovered such a particle—the neutron. In 1938, two German radiochemists, Otto Hahn and Fritz Strassmann, reported they had produced the element barium by bombarding uranium with neutrons.

At first, scientists could not explain how uranium had produced barium, which is much lighter than uranium. All previous transmutations had resulted in an element about as heavy as the original one. Then in 1939, the Austrian physicist Lise Meitner and her nephew Otto Frisch showed that Hahn and Strassmann had in fact produced the first known artificial fission reaction. A uranium nucleus had split into two nearly equal fragments, one of which consisted of a barium nucleus. Two neutrons were also emitted. The other fragment consisted of a nucleus of krypton, a somewhat lighter element than barium. These two nuclei, together with the emitted neutrons, are lighter than a uranium nucleus and a neutron. The reaction had therefore produced more energy than it consumed.

Scientists soon realized that if many uranium nuclei could be made to fission, a tremendous amount of energy would be released. The amount of energy could be calculated from a theory developed by the great German-born physicist Albert Einstein in 1905. The theory shows that matter can change into energy and that matter and energy are related by the equation $E = mc^2$. This equation states that the *energy (E)* into which a given amount of matter can change equals the *mass (m)* of that matter multiplied by the *speed of light squared (c^2).* The speed of light squared is obtained by multiplying the speed of light by itself. Using this equation, scientists determined that the fissioning of 1 pound (0.45 kilogram) of uranium would release as much energy as 8,000 tons (7,300 metric tons) of TNT. Uranium could therefore be used to make a powerful bomb.

The development of nuclear weapons. World War II broke out in Europe in September 1939. The month before, Einstein had written to U.S. President Franklin D. Roosevelt urging him to commit the United States to developing an atomic bomb. Einstein had fled to the United States from Germany to escape Nazi persecution. He warned Roosevelt that German scientists might already be working on a nuclear bomb. Roosevelt acted on Einstein's urging, and early in 1940 scientists received the first funds for uranium research in the United States.

Detail of a 1957 painting by Gary Sheahan; Chicago Historical Society (University of Chicago)

The first nuclear reactor was built by scientists at the University of Chicago beneath the stands of the university's athletic field. The reactor, made of tons of uranium oxide and uranium embedded in graphite, produced the first artificial chain reaction in 1942.

The United States entered World War II in 1941. The government then ordered an all-out effort to build an atomic bomb and in 1942 established the top-secret Manhattan Project to achieve this goal (see **Manhattan Project**).

A group of scientists at the University of Chicago had charge of producing plutonium for the Manhattan Project. The group included such noted physicists as Enrico Fermi, Leo Szilard, and Eugene Wigner, all of whom had been born in Europe and had settled in the United States. Fermi headed the group. Under the scientists' direction, workers built an atomic *pile,* or reactor, beneath the stands of the university athletic field. The pile consisted of 50 tons (45 metric tons) of natural uranium oxide and uranium embedded in 500 tons (450 metric tons) of graphite. The graphite served as a moderator. The pile was designed to demonstrate a controlled nuclear chain reaction in the uranium. Cadmium rods controlled the reaction. On Dec. 2, 1942, this reactor produced the first artificial chain reaction.

The success of the University of Chicago project led the U.S. government to build a plutonium-producing plant in Hanford, Washington. The government also built a uranium enrichment plant in Oak Ridge, Tennessee. Plutonium and greatly enriched uranium from these plants were used in the two atomic bombs that the United States dropped on Japan in August 1945.

After World War II, scientists began work on developing a hydrogen bomb. The United States exploded the first hydrogen bomb in 1952 and so achieved the world's first large-scale thermonuclear reaction. The Soviet Union tested its first atomic bomb in 1949 and its first full-scale hydrogen bomb in 1953. China, France, India, Pakistan, South Africa, and the United Kingdom have also exploded nuclear weapons. For more information on the development of nuclear weapons, see **Nuclear weapon.**

The first peaceful uses. While research on nuclear weapons continued, various countries also began experimenting with nuclear reactors. The United States and the Soviet Union had built uranium enrichment plants for nuclear weapons. Both countries therefore started to develop light water reactors, which require enriched uranium fuel. Canada, France, and the United Kingdom worked on reactors moderated by graphite or heavy water. These reactors cost more to build than light water reactors but use unenriched uranium.

The U.S. Congress set up the Atomic Energy Commission (AEC) in 1946 to direct and control all aspects of nuclear energy development in the United States. In 1954, Congress allowed private industry to take over most aspects of commercial nuclear power development. But the AEC became responsible for regulating the nuclear energy industry. It also kept control in such areas as uranium enrichment and waste disposal.

The United States made the world's first full-scale use of controlled nuclear energy in 1954. That year, the U.S. Navy launched the first nuclear-powered vessel, the submarine *Nautilus.* The world's first full-scale nuclear power plant began operations in 1956 at Calder Hall in northwestern England. In 1957, the first large-scale nuclear plant in the United States opened in Shippingport, Pennsylvania. It supplied electric power to the Pittsburgh area until 1982, when the plant was closed. Canada opened its first full-scale plant in 1962 at Rolphton, Ontario.

The successful start of the nuclear power industry convinced world leaders of the need for international cooperation in the field. In 1957, the United Nations (UN) established the International Atomic Energy Agency to promote the peaceful uses of nuclear energy (see **International Atomic Energy Agency; United Nations** [Peaceful uses of nuclear energy]). Also in 1957, Belgium, France, Italy, Luxembourg, the Netherlands, and West Germany formed the European Atomic Energy Community (Euratom). The organization encourages the development of nuclear power among its member countries. Today, the countries that make up the European Union are all members of Euratom (see **European Union**).

The spread of nuclear capability. During the 1960's and early 1970's, a number of countries acquired reactors and used them to start nuclear power development. Progress was also made during this period toward limiting nuclear weapons tests and stopping the spread of nuclear weapons. In 1970, for example, a nuclear *nonproliferation treaty* went into effect. The treaty prohibits the nuclear powers that have agreed to abide by the document from giving nuclear weapons to nations that do not already have them. The nonproliferation treaty also prohibits nations without nuclear weapons from acquiring them.

But the nonproliferation treaty does not prohibit nations from selling or buying nuclear reactors. A reactor can be used not only for peaceful purposes but also to produce plutonium for nuclear weapons. India used a research reactor for this purpose and in 1974 exploded its first atomic bomb. Canada had supplied the reactor to India with the understanding it would be used for peaceful purposes only. Canada has signed the nonproliferation treaty, but India has not. Critics of India's action question the wisdom of supplying reactors to countries that do not already have them.

Meanwhile, the United States had been greatly increasing its nuclear power capacity. But opposition to nuclear power development also increased in the United States during the late 1960's and early 1970's. Critics began to question nearly every aspect of nuclear power production, from the cost of uranium enrichment to the problems of waste disposal.

Many critics of the United States nuclear program charged that the government overlooked various safety risks at nuclear plants to promote nuclear power development. Partly as a result of such criticism, Congress disbanded the Atomic Energy Commission (AEC) in 1974 and divided its functions between two newly formed agencies. The Energy Research and Development Administration (ERDA) took over the AEC's development programs. The Nuclear Regulatory Commission (NRC) took over its regulatory duties. The NRC, it was believed, could better regulate the industry if it was not also responsible for the industry's growth and development. In 1977, Congress abolished ERDA and transferred its responsibilities to the newly created Department of Energy. See **Energy, Department of; Nuclear Regulatory Commission.**

In 1992, the U.S. Congress passed the Energy Policy Act, opening the way for deregulation of the electric power industry. Since then, many nuclear utilities have

Sovfoto

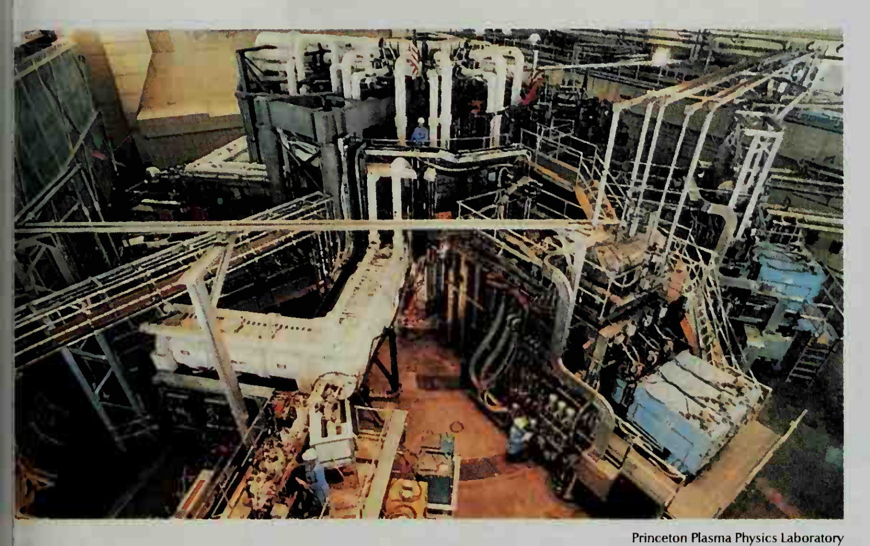
consolidated. In 2000, the NRC began approving extensions of operating life for existing nuclear plants.

Safety concerns. There have been a number of accidents at nuclear power plants. Most have not been serious. However, in 1957, a fire at the Windscale plutonium production plant in northern England resulted in the release of a large quantity of radioactivity. The British government banned the sale of milk from cows in that part of England for more than a month after the fire.

In the United States, concerns about the safety of nuclear reactors increased after a serious accident in 1979 at the Three Mile Island nuclear power plant near Harrisburg, Pennsylvania. Mechanical and human failures resulted in a breakdown of the reactor's cooling system and the destruction of the reactor core. Scientists and technicians prevented a failure of the reactor vessel that might have released large amounts of radioactive isotopes into the reactor containment building. Cleanup of the plant was completed in the early 1990's.

The worst nuclear accident in history occurred in 1986 at the Chernobyl nuclear power plant near Kiev in Ukraine, which was then part of the Soviet Union. An explosion and fire ripped apart the reactor and released large amounts of radioactive isotopes into the atmosphere. Unlike most Western reactors, the Chernobyl reactors lacked an enclosure to prevent radioactive isotopes from escaping. Soviet officials reported that 31 people died from radiation sickness or burns and more than 200 others were seriously injured. The radioactive substances spread over parts of what are now Ukraine, Russia, and Belarus, and were carried by wind into northern and central Europe. Experts expected a significant increase in the number of cancer deaths among those near the reactor. But they predicted that the health effects outside the area would be slight. The last working reactor at Chernobyl was shut down in 2000.

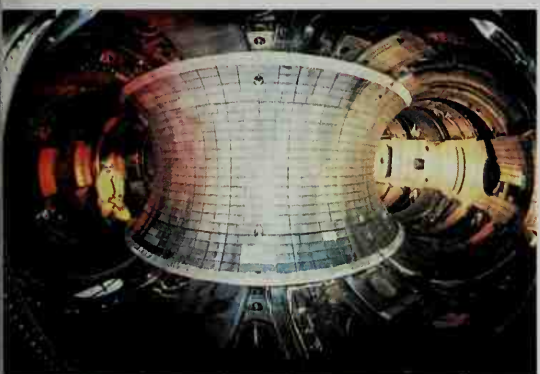
As a result of the accidents at Three Mile Island and Chernobyl, opposition to nuclear power increased in many countries during the late 1980's. In the United States, the NRC tightened its control of nuclear plants.



Experts have expressed particular concern over the safety of older Soviet-designed reactors now operating in Russia, Ukraine, and several countries of the former Soviet bloc. Western scientists and engineers are helping to remedy some of the most urgent safety problems in these reactors.

As the nuclear power industry has continued to develop, many improvements in plant equipment and operation have increased safety. Nonetheless, some experts insist that the next generation of reactors should take greater advantage of design features that rely less—or not at all—on mechanical equipment such as pumps and valves to remove heat if an accident occurs. Some of these reactors are known as *passively safe reactors.* The following section on *Research on new types of reactors* describes some of these proposed reactors.

Research on new types of reactors. New research on reactors was sparked by fears of a shortage of U-235 to fuel fission reactors. However, during the 1970's nuclear power production increased less rapidly than expected. Geologists also discovered that there was much more uranium on earth than had originally been estimated. Therefore, the expected near-term shortage did not occur.



Today, scientists seek to develop safer and more efficient reactors. Researchers have concentrated their efforts on the development of a fusion reactor and advanced fission reactors.

Experimental fusion devices. Most experiments on controlled nuclear fusion have concentrated on the de-

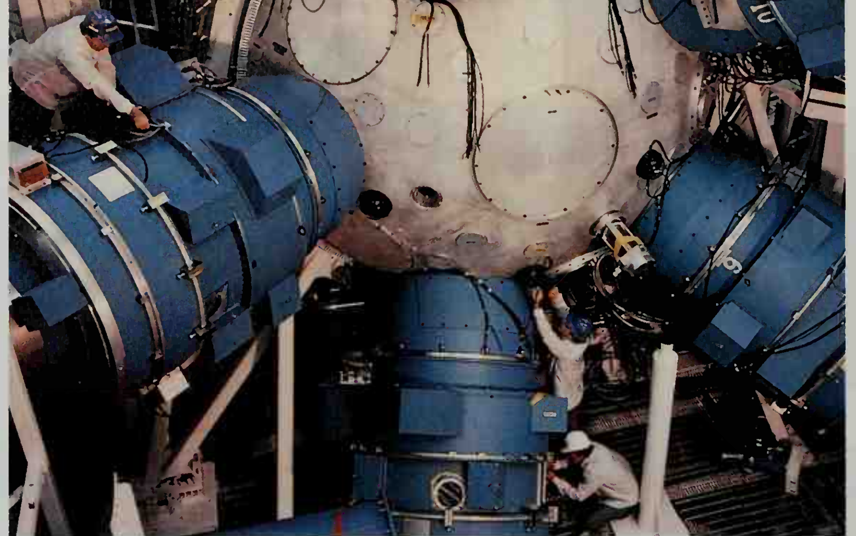
side a tokamak is a chamber, being examined here by a orker, in which hydrogen nuclei are forced to fuse. The tokaak produces fusion by heating a *plasma* (a mixture of nuclei id electrons) to at least 180,000,000 °F (100,000,000 °C).

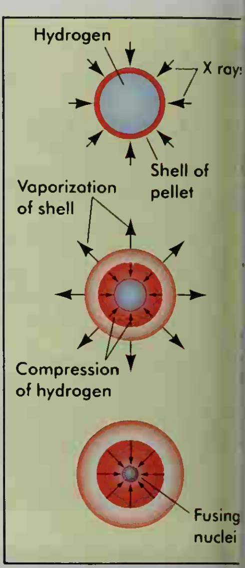
WORLD BOOK illustration by Roberta Polfus

Plasma in a tokamak is held away from the chamber walls by a magnetic field produced by two sets of magnets. If the plasma were to touch the walls, its temperature would fall so sharply that nuclei in the plasma could not fuse.



›lopment of reactors that would use deuterium and itium plasma as the fuel. The most successful type of sion reactor, called a *tokamak,* was originally designed / Soviet scientists. The term *tokamak* comes from Rusan words meaning *toroidal* (doughnut-shaped) *chamer and magnetic coil.* Like many other experimental fuon reactors, a tokamak uses *magnetic confinement.* A agnetic field pushes plasma away from the tokamak's ›ntaining walls. The tokamak also passes a strong elecic current through the plasma. The current interacts ith the magnetic field to help confine the plasma.

One goal of fusion research is to reach the *breakeven vel,* the level of energy production equal to the energy ›eded to create and heat the plasma. To reach this lev-, a tokamak of the design presently under developent must heat the plasma to at least 180,000,000 °F)0,000,000 °C). Also, each cubic centimeter (0.061 cubic ch) of the plasma must contain about 100 trillion nuei, and the magnetic field must confine the plasma for ›out 1 second.



Researchers working with tokamaks have reached ese three goals, but never in the same experiment. By e mid-1990's, individual experiments on plasmas made up of deuterium and tritium atoms had achieved about 30 percent of the breakeven level.

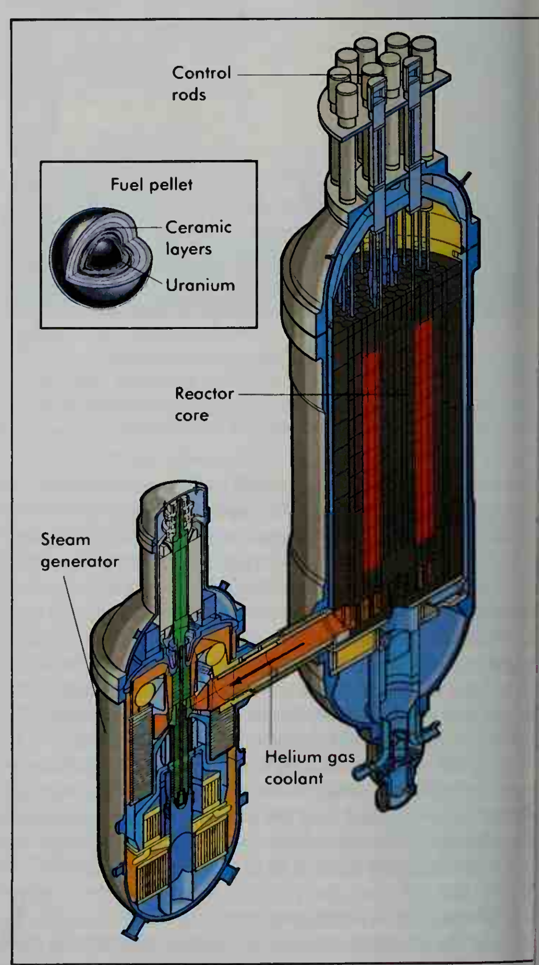
Another kind of fusion reactor uses *inertial confinement.* In this case, no container holds the fuel during fusion. Rather, the fuel's *inertia,* its natural tendency to remain in the same place, holds it long enough for fusion to occur. In one kind of inertial confinement fusion (ICF) reactor, extremely powerful laser beams strike a cylindrical case made of metal. Inside the case is a pea-sized sphere containing deuterium and tritium gas. The laser beams heat the case, causing it to turn to plasma. The plasma, in turn, bombards the sphere with X rays, rapidly heating the shell of the sphere. As a result, the shell both expands and pushes inward. The inward push compresses the fuel, causing fusion.

The most powerful laser-driven reactor was the Nova device at Lawrence Livermore National Laboratory in Livermore, California. Nova operated from 1985 to 1999. At its peak power, Nova could deliver up to 40,000 *joules* of energy in a pulse lasting 1 billionth of a second. One joule is the amount of work done when a force of 1 newton moves an object 1 meter in the direction of the force.

Lawrence Livermore National Laboratory

WORLD BOOK diagram by Mark Swinc

An inertial confinement fusion reactor heats a target so rapidly that nuclei fuse before the target can fly apart. Laser beams hit a target in a spherical chamber, *above,* producing X rays. The rays strike a hydrogen-filled pellet, *right,* vaporizing its shell and compressing the hydrogen. The hydrogen becomes so hot that nuclei fuse.



Advanced fission reactors. Research, development, and design work on advanced fission reactors has concentrated on advanced versions of today's light-water reactors (LWR's), other types of advanced thermal reactors, and fast reactors. The goals of this work include improved operating efficiency, simplified design, lower cost, and increased use of *passive* safety systems. A passive safety system is one that does not depend upon mechanical devices, such as pumps and valves, to prevent core damage and remove heat from the core if an accident occurs.

A type of fission reactor that is currently operating in Japan—and which the NRC has certified for use in the United States—is the *advanced light water reactor* (ALWR). Many ALWR's are smaller than today's LWR's, and they have many passive safety features. One ALWR design relies on gravity, rather than pumps, to circulate a supply of cooling water that would be needed in certain emergencies.

A *high-temperature gas-cooled reactor* (HTGR) is a small unit that uses a gas, usually helium, as the coolant. The fuel consists of ceramic-coated pellets of uranium oxycarbide. The purpose of this design is to make it impossible for the fissions in a pellet to produce enough heat to rupture the casing, even if the reactor were to lose all its coolant. If the pellets remained intact, radioactive material would not be released.

A group of reactors known as *fast reactors* have long-term advantages. A fast breeder reactor can be designed to both consume plutonium as a fuel and convert U-238 to more plutonium. The new plutonium, in turn, can be used as reactor fuel. The breeder thus creates more fissionable material than it consumes. Because uranium is plentiful, the use of breeders would extend its potential as an energy resource enormously. Several countries have built experimental breeders. A unit in France, called the Superphénix, is the most powerful. It can produce 1,200,000 kilowatts of electric power.

Fast reactors can also be developed to consume some of the long-lived radioactive materials, such as plutonium and americium in spent fuel, thus avoiding

Nuclear fission. See Fission; Nuclear energy.

Nuclear Nonproliferation Treaty is an international agreement that attempts to prevent the spread of nuclear weapons. Its official name is the Treaty on the Non-Proliferation of Nuclear Weapons. The pact was approved by the United Nations in 1968 and took effect in 1970. Under the treaty's terms, after 25 years it was to be extended for a fixed period or made permanent. In 1995, the pact's signers agreed to make it permanent.

Under the treaty, nations that have nuclear weapons agree (1) not to help countries that do not already have such weapons acquire them; (2) to help nonnuclear-armed countries benefit from the peaceful uses of nuclear energy; and (3) to seek nuclear disarmament. Also, countries without nuclear weapons agree (1) not to acquire nuclear weapons and (2) to accept safeguards arranged by the International Atomic Energy Agency (IAEA). The safeguards allow the IAEA to inspect nuclear facilities and materials in each country.

A vast majority of all countries have ratified the treaty, including such nuclear-armed nations as China, France, Russia, the United Kingdom, and the United States. China and France did not ratify the pact until 1992. Some countries that have not agreed to the treaty either possess nuclear weapons or are able to produce them. These nations include India, Israel, and Pakistan.

Robert E. Williams

Nuclear physics is the study of atomic nuclei and the application of nuclear processes to technology. Nuclear physics began in about 1900 as the study of radioactive materials, such as radium and uranium.

Three major nuclear processes are (1) *radioactivity,* involving the decay of a nucleus; (2) *fission,* the breakup of a nucleus to form two smaller nuclei; and (3) *fusion,* the joining of two nuclei to form a larger nucleus. Both fusion and fission create the energy of nuclear weapons.

Radioactivity is the *emission* (giving off) of particles and energy by a nucleus. An atomic nucleus lies at the center of an atom. The simplest nucleus is that of the lightest *isotope* (form) of hydrogen. This nucleus consists of a single particle, called a *proton,* which carries a positive electric charge. All other nuclei consist of at least one proton and one *neutron.* A neutron has internal charges that cancel one another out, making it electrically neutral.

The location of individual protons and neutrons in a nucleus depends on their energy and other factors. The protons and neutrons of certain isotopes, called *radioisotopes,* will change their locations by means of radioactive decay. In one kind of decay, two protons and two neutrons leave the nucleus together as a unit known as an *alpha particle.* Decay occurs *spontaneously*—that is, no input of particles or energy is needed to trigger it.

Physicians can use radioisotopes to diagnose disease. To detect heart ailments, for example, doctors inject a radioactive substance called a *tracer* into a patient's bloodstream. A camera equipped with a radiation detector then records the flow of the tracer through the heart. In another medical application, physicians treat cancer by bombarding tumors with radiation.

Other scientists make use of the fact that radioisotopes decay at an exact and uniform rate. One application, known as *radiocarbon dating,* uses the rate of decay of a carbon isotope to determine the age of ancient plants and animals.

Fission creates energy in a nuclear power plant. In this process, a heavy nucleus, such as a uranium nucleus, absorbs a subatomic particle, then splits into two smaller nuclei. In each fission, a tiny amount of nuclear matter changes into heat energy. Electric generators in the power plant convert the heat to electric energy.

Fusion powers the sun and other stars. In one kind of fusion reaction, two protons come together. One of them emits a positively charged particle called a *positron* and a neutral particle known as a *neutrino.* The emissions turn the proton into a neutron, so the resulting nucleus consists of a proton and a neutron. During fusion, some nuclear matter changes into heat energy. Scientists are experimenting with ways to produce electric energy from the energy of fusion. William Karl Pitts

Nuclear reactor is a device in which controlled nuclear fission reactions take place. See **Isotope** (Artificial radioisotopes); **Nuclear energy** (Power reactors); **Rocket** (Nuclear rockets; picture); **Submarine** (The power plant; pictures).

Nuclear Regulatory Commission is an independent agency of the United States government. The commission, also called the NRC, was organized to ensure that the use of nuclear energy for civilian purposes does not endanger the health and safety of the public and the environment. It licenses and oversees the construction and operation of nuclear reactors that produce electric power. The NRC also regulates the use of radioactive materials in agriculture, industry, and medicine, and the packaging of such materials for transport.

The Energy Reorganization Act of 1974 abolished the Atomic Energy Commission (AEC) and replaced it with the NRC and the Energy Research and Development Administration (ERDA). The NRC began operations in 1975. In 1977, ERDA was abolished and its responsibilities were transferred to the Department of Energy.

Critically reviewed by the Nuclear Regulatory Commission

Nuclear waste. See Nuclear energy (Wastes and waste disposal).

Nuclear weapon is any weapon that gets its destructive power from the transformation of matter in atoms into energy. All nuclear weapons are explosive devices. They are carried in missiles, bombs, artillery shells, mines, or torpedoes. The most powerful nuclear weapons are far more destructive than any *conventional* (nonnuclear) weapon.

Nuclear weapons can be *fission weapons,* also called *atomic bombs* or *atomic weapons,* or they can be *thermonuclear weapons,* also known as *hydrogen bombs, hydrogen weapons,* or *fusion weapons.* In fission weapons, matter converts to energy when the *nuclei* (cores) of certain kinds of uranium or plutonium atoms are split. Thermonuclear weapons convert matter to energy by combining pairs of certain kinds of hydrogen nuclei to form single nuclei. Thermonuclear weapons are generally far more powerful than fission weapons. Most nuclear weapons are thermonuclear.

The first nuclear weapons were two fission bombs dropped by the United States on the Japanese cities of Hiroshima and Nagasaki during World War II (1939-1945). The bombs killed from 110,000 to 140,000 people and destroyed large areas of both cities. The terrible destruction caused by the bombs became a major factor in Japan's decision to surrender to the United States and its Allies. Japan's surrender ended the war. The bombs exploded at Hiroshima and Nagasaki are the only two nuclear weapons that have ever been used.

Most experts believe that the threat of nuclear war probably helped keep the peace during the Cold War, a period of intense hostility between Communist and non-Communist nations, and their respective allies, following World War II. To avoid the terrible damage that nuclear weapons could cause, many nations have long sought ways to control such weapons and reduce the risk of nuclear war.

The United States and Russia have most of the world's nuclear weapons. The United Kingdom and France also developed small, potent *arsenals* (supplies) of nuclear weapons during the Cold War. Other countries that possess nuclear arms include China, India, Pakistan, and South Africa. Several other nations may have the ability to build nuclear weapons.

The growing number of nuclear powers increases the danger that regional tensions could possibly lead to use of nuclear weapons. An example of such tensions was a crisis between India and Pakistan in the disputed region of Kashmir in 2002. Troops on both sides exchanged artillery fire, and the two countries, both with nuclear weapons, seemed on the brink of war. Tensions also run high in the Middle East. Many experts believe the Middle Eastern nations of Israel, Iraq, and Iran either possess or are close to building nuclear weapons. Other threats may involve terrorist groups without governmental ties that could acquire and use nuclear devices.

How nuclear weapons work

Fission weapons generate their destructive power through the *fission* (splitting) of atomic nuclei. The only three materials known to be fissionable in weapons are two isotopes of uranium (U), U-235 and U-238, and one isotope of plutonium (Pu), Pu-239. Isotopes are different kinds of atoms of the same element. Each kind has a different *mass* (total amount of matter). See **Isotope**.

Nuclear fission occurs when a *neutron*—a subatomic particle with no electric charge—strikes the nucleus of a uranium or plutonium atom. Splitting the nucleus transforms a small amount of its matter into a large amount of energy. In addition, two or three additional neutrons are released. These neutrons may then split other nuclei. If this process continues, a self-sustaining *chain reaction* begins in which many nuclei split rapidly, and their combined energies produce a fission explosion.

Generating a self-sustaining chain reaction requires a minimum amount of fissionable material known as the *critical mass.* A mass too small to support a self-sustaining chain reaction is called a *subcritical mass.*

A fission weapon uses one of two methods to create a

Photri

Photri

Nuclear weapons include missiles and artillery shells. The top photograph at the left shows the launching of two long-range nuclear missiles. Such missiles carry extremely powerful thermonuclear devices. The explosion of such a device creates a huge mushroom-shaped cloud like the one shown at the right. A self-propelled howitzer, *bottom left,* can fire nuclear artillery shells.

critical mass: (1) the *gun-type method* or (2) the *implosion method.* In the gun-type method, two subcritical pieces of material are placed in a device similar to the barrel of a gun. One piece rests at one end of the barrel. The other is some distance from the first piece, with a powerful conventional explosive behind it. The barrel is sealed at both ends. When the weapon's fuse is triggered, the conventional explosive propels the second subcritical mass at high speed into the first. The resulting combined mass immediately becomes *supercritical* (greater than critical), causing a rapid, self-sustaining chain reaction, and thus a nuclear explosion. The United States used a gun-type fission bomb at Hiroshima.

In the implosion method, a subcritical mass is made supercritical by compressing it into a smaller volume. The subcritical mass is in the center of the weapon, surrounded by conventional explosives. When the fuse is triggered, all the conventional explosives go off at the same time. The explosions compress the mass into a high-density supercritical mass. A self-sustaining chain reaction occurs, causing the explosion. The United States used an implosion-type fission bomb at Nagasaki.

Thermonuclear weapons get their power from the *fusion* (combining) of atomic nuclei under intense heat. The nuclei fused in thermonuclear weapons are of the hydrogen isotopes deuterium (H-2) and tritium (H-3).

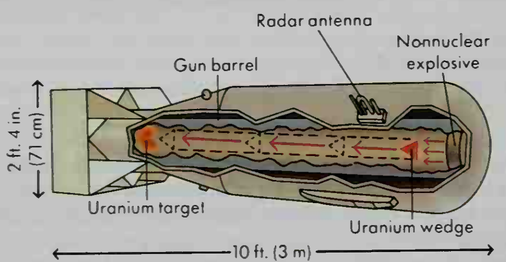
Fusion reactions require temperatures equal to, or greater than, those found in the sun's core—about 27,000,000 °F (15,000,000 °C). The only practical way to achieve such temperatures is by a fission explosion. Thus, an implosion-type fission device triggers thermonuclear explosions. When the fission device explodes, it also releases neutrons that bombard a compound inside the weapon. This compound, called *lithium 6 deuteride,* consists of deuterium and lithium 6 (Li-6), an isotope of the element lithium. When struck by the released neutrons, the Li-6 forms helium and tritium. Then, pairs of tritium nuclei, pairs of deuterium nuclei, and pairs of one tritium nucleus and one deuterium nucleus each fuse to form helium nuclei. A small amount of matter from each deuterium and tritium nucleus converts to a large amount of energy, and a thermonuclear explosion occurs. The *yield* (explosive power) of a thermonuclear weapon can be increased by blanketing the lithium 6 deuteride with the uranium isotope U-238. The U-238 fissions during the hydrogen explosion.

Effects of nuclear weapons

Nuclear explosive devices have different yields. Some older bombs had yields of about 20 *megatons,* equivalent to the yield of about 1,540 Hiroshima bombs. A megaton is the amount of energy released by 1 million tons (907,000 metric tons) of TNT. Today, most nuclear devices have yields of less than 1 megaton. Most large thermonuclear weapons are about 8 to 40 times as powerful as the Hiroshima bomb.

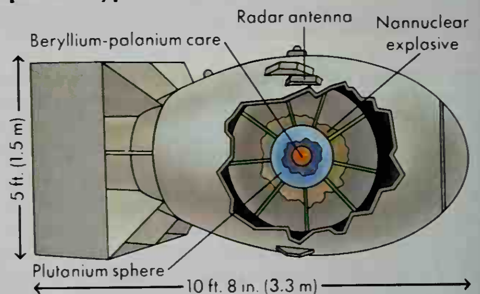
The effects of a nuclear explosion can vary greatly, depending on a number of factors. These factors include weather, terrain, the point of explosion in relation to Earth's surface, and the weapon's yield. This section describes the possible effects of a large nuclear weapon. The weapon's explosion would produce four basic effects: (1) a blast wave, (2) thermal radiation, (3) initial nuclear radiation, and (4) residual nuclear radiation.

Blast wave. The explosion begins with the formation of a *fireball,* a cloud of dust and extremely hot gases un-



der high pressure. A fraction of a second after the explosion, the gases begin to expand and form a blast wave, also called a *shock wave*. This wave is like a wall of highly compressed air moving rapidly away from the fireball. The blast wave created by a 1-megaton explosion could travel about 12 miles (19 kilometers) from *ground zero* in just 50 seconds. Ground zero is the point on the ground directly below the explosion.

The blast wave causes most of the explosion's damage. As the wave moves forward, it creates *overpressure*, atmospheric pressure above the normal level. A 1-megaton explosion can produce enough overpressure to destroy most buildings within 1 mile (1.6 kilometers) of ground zero. This overpressure can also cause moderate to severe damage within 6 miles (9.6 kilometers) of ground zero. Strong winds accompany the blast wave. These winds may reach speeds of 400 miles (640 kilometers) per hour at 2 miles (3.2 kilometers) from ground zero. The blast wave and wind probably would kill the majority of people within 3 miles (4.8 kilometers) of ground zero and some people between 3 and 6 miles (4.8 and 9.6 kilometers) from ground zero. Many other people within 6 miles of ground zero would be injured.



Thermal radiation consists of ultraviolet, visible, and infrared radiation given off by the fireball. Particles in the air rapidly absorb the ultraviolet radiation, and so it does little harm. However, the visible and infrared radiation can cause eye injuries as well as skin burns called *flash burns*. Flash burns caused from 20 to 30 percent of the deaths at Hiroshima and Nagasaki.

Thermal radiation also can ignite flammable materials, such as newspapers and dry leaves, causing large fires. Some scientists theorize that, in a nuclear war, the smoke from such fires would absorb enough sunlight to lower the temperature for several months or years. These scientists speculate that the lowered temperatures would result in widespread crop failure and famine. This possible effect of nuclear war is called *nuclear winter*. However, the effects of thermal radiation can vary considerably, depending on a number of condi-

Gun-type fission bomb

Implosion-type fission bomb

WORLD BOOK illustrations by J. Harlan Hunt (adapted from artwork by Van Dyke, Dec. 19, 1960, *Newsweek*)

UPI/Bettmann Newsphoto

Hiroshima, Japan, was largely destroyed by a gun-type fission bomb called the Little Boy bomb, *top,* on Aug. 6, 1945. The bomb was dropped from a B-29 bomber. When the bomb reached 1,850 feet (564 meters), a radar echo set off an explosive inside. This explosive drove a wedge of U-235 into a larger piece of U-235, setting off the nuclear blast. This photograph shows Hiroshima after the explosion.

Atomic Energy Commission

Nagasaki, Japan, was struck by an implosion-type fission bomb called the Fat Man bomb, *top,* on Aug. 9, 1945. In this bomb, an explosive crushed a hollow sphere of plutonium into a core made up of the chemical elements beryllium and polonium. This core then released neutrons, which triggered a fission chain reaction in the plutonium. This photograph shows Nagasaki after the nuclear blast.

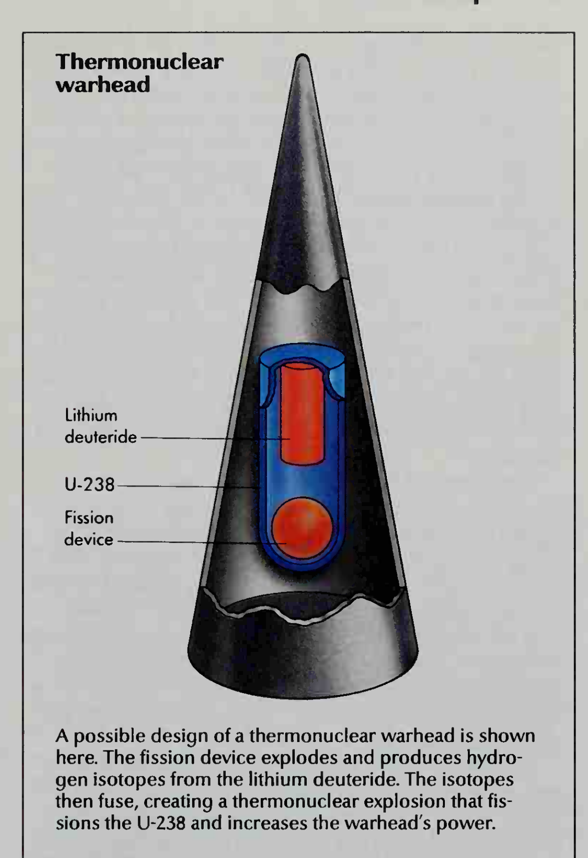
tions at the time of the explosion. In a light atmospheric haze, for example, the effects could be only one-hundredth as strong as they would be in clear air.

A person can be shielded from the direct effects of thermal radiation by solid, nontransparent objects, such as walls, buildings, trees, and rocks. In addition, light-colored clothing reflects heat, and so can help protect a person from flash burns. However, thermal radiation from a 1-megaton explosion can produce *second-degree burns* (blistering) of exposed human skin up to 11 miles (18 kilometers) from ground zero. The thermal radiation would last only about 10 seconds. Thus it would char, but not completely burn, heavy fabrics and thick pieces of wood or plastic.

Initial nuclear radiation occurs within the first min-ute beginning at the instant of the explosion. It consists of neutrons and *gamma rays,* a form of radiation similar o X rays. The fireball emits neutrons and some of the gamma rays almost instantaneously. The rest of the gam-na rays are given off by a huge mushroom-shaped cloud of radioactive material formed by the explosion. Nuclear radiation can destroy living cells and prevent normal cell replacement. Large doses of radiation can cause death. For more information about how radiation ffects the body, see **Radiation** (Effects of radiation) and **Radiation sickness.**

The amount of harm to a person from initial nuclear adiation depends in part on the person's location in re-ation to ground zero. Initial radiation decreases rapidly n strength as it moves away from ground zero. In all nu-lear explosions, for example, initial radiation at about $\frac{1}{3}$ o $\frac{2}{3}$ mile (0.5 to 1 kilometer) from ground zero is only bout one-tenth to one-hundredth as strong as radiation t ground zero.

Residual nuclear radiation is given off later than ne minute after the explosion. Residual radiation creat-d by fission consists of gamma rays and *beta particles* lectrons). Residual radiation produced by fusion is nade up primarily of neutrons. It strikes particles of ock, soil, water, and other materials that make up the nushroom-shaped cloud. As a result, these particles be-ome radioactive. They fall back to earth and are known s *fallout.* The closer an explosion occurs to Earth's sur-ce, the more fallout it produces.



Early fallout reaches the ground within 24 hours of e explosion. Its heavier particles are highly radioactive, nd most fall downwind from ground zero. Early fallout lls or severely injures living things.

Delayed fallout reaches the ground from 24 hours to number of years after the explosion. It consists of tiny, ten invisible, particles that may fall in small amounts er large areas. Such fallout causes long-term radiation mage to living things. See **Fallout.**

Types of nuclear weapons

Nuclear weapons can be divided into two main types, pending on the military role for which they are de-gned. These types are (1) *strategic nuclear weapons* d (2) *theater nuclear weapons.*

Strategic nuclear weapons are designed primarily launch an attack from great distances on targets in an emy's homeland. These weapons include bombs and ssiles delivered by long-range bomber aircraft. They o include missiles that can deliver explosive devices

A possible design of a thermonuclear warhead is shown here. The fission device explodes and produces hydrogen isotopes from the lithium deuteride. The isotopes then fuse, creating a thermonuclear explosion that fissions the U-238 and increases the warhead's power.

WORLD BOOK illustration by J. Harlan Hunt. Adapted from artwork in Howard Morland's *The Secret That Exploded,* Random House, 1981.

to targets up to 6,500 miles (10,500 kilometers) from the launch site. Some of these missiles are based on land. Others are based underwater on submarines. Strategic nuclear missiles include *intercontinental ballistic missiles* (ICBM's), *submarine-launched ballistic missiles* (SLBM's), and *cruise missiles.* See **Guided missile** (Ballistic missiles; Nonballistic missiles).

Some strategic nuclear missiles have several nuclear *warheads,* each of which carries explosive material to a separate target. These warheads are called Multiple Independently Targetable Reentry Vehicles (MIRV's).

Strategic nuclear weapons can destroy or disable an enemy's strategic nuclear weapons. They also can disrupt an enemy's economy or social organization.

Theater nuclear weapons are designed for use within a *military theater,* a large area in which military operations may be conducted. Smaller or shorter-range theater nuclear weapons are also called *tactical nuclear weapons.* Theater nuclear weapons can be used to attack conventional forces during a battle or military campaign, or to attack the enemy's theater nuclear weapons. Theater nuclear weapons include medium-range ballistic and cruise missiles, and short-range guided missiles and unguided rockets. They also include artillery shells, nuclear mines, and torpedoes.

Nuclear weapons in military planning

For nearly 50 years following World War II, nuclear weapons dominated the military planning of the United

States and the Soviet Union, the world's leading military powers. Their national arsenals of nuclear weapons increased and decreased as tensions between the countries grew and declined. But nuclear weapons have changed their military role over time, and several regional military powers have acquired such weapons.

The United States. In the mid-1930's, some U.S. military planners began to see airpower as the best means of ending a war quickly. They favored using bombers to strike a quick, crushing blow against an aggressor's homeland. During World War II, this *airpower theory* led the United States to drop many conventional bombs on Germany and Japan. However, the war lasted several years despite the bombing. Germany surrendered only after Allied ground forces defeated its army. Japan surrendered soon after nuclear bombs hit Hiroshima and Nagasaki.

Supporters of the airpower theory thought that Japan's surrender after the use of nuclear bombs confirmed their theory. As a result—and because it is far cheaper to build and maintain nuclear weapons than conventional forces—nuclear weapons became central to U.S. strategic military power during the Cold War.

In the mid-1950's, the United States adopted the policy of *massive retaliation.* This policy stated that if Soviet forces struck any area vital to the United States or its allies, the United States might respond with a major nuclear strike against the Soviet Union.

In the early 1960's, the policy of massive retaliation was replaced by that of *flexible response.* Under this policy, the U.S. response to enemy aggression would match the nature of the aggressor's attack. The United States could use any type of weapon to stop the attack, including conventional forces or nuclear weapons.

In the 1980's, advances in conventional military tactical practices and in military technologies made possible a sweeping transformation of strategy that military planners called the *revolution in military affairs* (RMA). The RMA included a shift from large forces and massive bombing to precision strikes, using "smart" munitions, delivered by smaller, more agile forces. The United States and other nations with modern technology turned increasingly to new and highly advanced conventional weapons instead of nuclear arms. In 1990, the United States announced that it would use a nuclear weapon only as a last resort. Elements of the RMA proved effective against Iraq in the Persian Gulf War of 1991 and in operations in Yugoslavia in 1999 and in Afghanistan in 2002.

The Soviet Union. Beginning in the 1930's, Soviet planners based their military strategy on the *deep battle theory.* They stressed the use of all available weapons in a fast, overwhelming, and, when possible, surprise offensive. Most experts believed such a strike could include nuclear weapons. The Soviet nuclear arsenal consisted mainly of large land-based missiles. The Soviet focus on surprise offensives especially concerned U.S. planners, because a portion of the Soviet nuclear arsenal might have crippled U.S. missile and bomber forces in a *first strike* (initial nuclear attack).

Control of nuclear weapons

Because of the great dangers associated with nuclear weapons, many nations have made attempts to control them. The chief approaches to control have been strategies of deterrence and the placing of limits on the testing, numbers, and proliferation of nuclear weapons.

Deterrence refers to preventing the countries that have nuclear weapons from using them. Theories of deterrence may be offense-based or defense-based.

Offense-based deterrence theory holds that the possession of a strong nuclear force by opposing nations best prevents nuclear war. Forces must be so large that, even if attacked first, a defender would retain enough weapons to devastate an aggressor. The theory relies on a potential aggressor's belief that, no matter how powerfully it attacks, it will suffer a counterattack and unacceptable destruction in return. The theory was widely called the doctrine of *mutually assured destruction* (MAD).

Offense-based deterrence depends on nations being unable to defeat or seriously limit a nuclear strike against them. In 1972, the Strategic Arms Limitation Talks (SALT) between the United States and the Soviet Union concluded with a treaty called SALT I, which included strict limits on each country's defenses against nuclear missiles. Such defenses use *antiballistic missiles* (ABM's) to destroy incoming nuclear missiles before they reach their targets. SALT I's ABM Treaty limited each nation to one missile *site* (permanent location) with only 100 missiles.

Defense-based deterrence theory agrees with offense-based theory that a major nuclear power will not attack unless it is sure it can destroy a victim's ability to launch a nuclear counterattack. However, defense-based theory also holds that only an effective defense against a powerful first strike will reliably protect a defender's ability to counterattack.

In cases of threat from a limited nuclear attack, many military experts hold that an effective defense will either deter the attack or, at least, limit major destruction. However, no country today has an effective defense. From 1983 to 1993, the United States carried out research on a program known as the Strategic Defense Initiative (SDI), a space-based system of defense against missiles. SDI was originally intended as a complete protection against nuclear attack, but in later stages, it aimed to protect against more limited nuclear attacks. See **Strategic Defense Initiative.**

By 2000, many people in the United States supported the idea of building a limited defense against attacks by small numbers of nuclear weapons that might be launched by terrorist groups or by what some leaders call "rogue nations"—small or medium-sized nations that ignore international law and support terrorism. Others objected that developing such a national missile defense system would violate the 1972 ABM Treaty, a major part of SALT I. Following terror strikes against the United States on Sept. 11, 2001, the United States withdrew from the ABM Treaty in June 2002 and increased spending on a defensive system.

Limiting testing. Nations have sought to limit the testing of nuclear weapons to protect people and the environment from nuclear radiation and to slow the development of nuclear weapons. In 1963, the Soviet Union, the United Kingdom, and the United States negotiated the first—and still chief—test limitation treaty, the Limited Test Ban Treaty. They agreed not to test nuclear

weapons in the atmosphere, in outer space, or underwater. Only underground testing was not banned.

In 1974, the United States and the Soviet Union agreed not to test explosive devices with yields above 150 *kilotons.* A kiloton is the amount of energy released by 1,000 tons (907 metric tons) of TNT. This agreement, contained in the Threshold Test Ban Treaty, took effect in 1990, the year it was ratified by both countries. But both nations had followed the treaty's guidelines long before ratification.

In 1996, the United Nations approved the Comprehensive Nuclear Test Ban Treaty, which would end all testing of nuclear weapons. To go into effect, the treaty must be ratified by all countries that have *nuclear reactors* (devices for producing nuclear energy). About three-fourths of the countries with reactors have ratified the treaty.

Limiting numbers. Attempts to limit the number of U.S. and Soviet nuclear weapons began about 1970. The first efforts, under the SALT approach, imposed limits at then-existing levels for some weapons and at higher levels for others. Both nations ratified the 1972 SALT I treaty. However, the U.S. Senate refused to ratify the 1979 SALT II treaty after Soviet forces invaded Afghanistan. See **Strategic Arms Limitation Talks.**

In 1982, U.S. President Ronald Reagan began the Strategic Arms Reduction Talks (START). These talks aimed for the first time at deep reductions in offensive strategic weapons. The START approach took root in 1987, when Reagan and Soviet President Mikhail S. Gorbachev signed the Intermediate-Range Nuclear Forces (INF) Treaty. This treaty called for the elimination of all U.S. and Soviet ground-launched nuclear missiles with ranges of 500 to 5,500 kilometers (310 to 3,420 miles). It took effect in 1988.

Efforts to limit nuclear weapons quickened following the INF Treaty. From 1989 to 1992, major political reforms in the Soviet Union and Eastern Europe, including the fall of most Communist governments, led to reduced tensions and general arms reductions. In 1990, the United States, the Soviet Union, and 20 other nations signed the Treaty on Conventional Armed Forces in Europe (CFE). The CFE Treaty, which took effect in 1992, called for the destruction of large numbers of tanks and other conventional weapons in Europe.

With international tensions reduced, and the INF and CFE treaties achieved, U.S. President George H. W. Bush and Soviet President Gorbachev in July 1991 signed the first treaty to significantly reduce existing numbers of strategic nuclear weapons. The Strategic Arms Reduction Treaty, now known as START I, aimed to reduce U.S. and Soviet long-range nuclear missiles and bombers from 23,500 to 15,400. START I officially took effect in 1994. Soon after its signing, in September 1991, the United States announced that it would destroy all of its ground-based tactical nuclear weapons and many of those carried by ships and aircraft. The following month, the Soviet Union announced similar steps.

The Soviet Union broke up in December 1991, seemingly ending the immediate threat of large-scale nuclear war. The United States and the four states that controlled portions of the former Soviet Union's nuclear arsenal—Russia, Ukraine, Belarus, and Kazakhstan—recommitted themselves to START I in May 1992.

In 1993, U.S. President George H. W. Bush and Russian President Boris Yeltsin signed START II, a new arms-reduction treaty that aimed to cut the total number of strategic nuclear weapons in the United States and the former Soviet republics to between 6,000 and 7,000. START II also called for the elimination of land-based MIRV's. By late 1996, Ukraine, Belarus, and Kazakhstan had turned over all their nuclear weapons to Russia. In May 2002, U.S. President George W. Bush and Russian President Vladimir Putin signed an agreement to further cut their strategic nuclear arsenals to between 1,700 and 2,200 warheads for each country by 2012.

Limiting proliferation involves preventing the spread of nuclear weapons to nations that do not have them. In 1968, the United Nations approved the Treaty on the Non-Proliferation of Nuclear Weapons. The treaty has since been ratified by nearly all countries.

History

The beginnings. Scientists gained an understanding of the basic structure of the atom during the late 1800's and early 1900's. In 1938, researchers discovered that splitting the nucleus of a uranium atom released much energy. See **Atom** (Development of the atomic theory); **Nuclear energy** (The development of nuclear energy).

World War II. By early 1939, only months before the start of World War II, physicists in the United States had become aware of the potential military applications of nuclear energy. They became concerned that Nazi Germany might develop a nuclear weapon.

In August 1939, the German-born physicist Albert Einstein helped alert U.S. President Franklin D. Roosevelt to the potential military applications of nuclear fission. World War II began on Sept. 1, 1939. The United States entered the war in December 1941. In 1942, the U.S. government set up the Manhattan Project to design and build a fission bomb.

On July 16, 1945, Manhattan Project scientists led by the American physicist J. Robert Oppenheimer exploded the first experimental nuclear device. It was a 22-kiloton implosion-type fission device. The test, at the Trinity test site near Alamogordo, New Mexico, convinced U.S. leaders that fission weapons could be built.

The first nuclear weapon used against Japan was a gun-type fission bomb. Its yield was about 13 kilotons. The bomb was dropped from an American B-29 aircraft on the city of Hiroshima on Aug. 6, 1945. Three days later, another B-29 dropped a 22-kiloton implosion-type fission bomb on Nagasaki, Japan. These bombs largely destroyed both cities, but the number of deaths differed greatly. The smaller bomb killed from 70,000 to 100,000 people in Hiroshima, which has a flat terrain. The larger bomb killed about 40,000 in Nagasaki, which has hilly terrain. Other people in both cities died later of injuries and radiation. On Aug. 14, 1945, Japan agreed to surrender, ending World War II.

The Cold War. By the late 1940's, tension between the Soviet Union and the United States led to a bitter struggle known as the Cold War. During the Cold War, many nuclear weapons were developed. See **Cold War.**

In 1949, the Soviet Union tested its first fission device in the midst of rising tension. In 1952, during the Korean War, the United States exploded the first experimental thermonuclear device. The Soviet Union set off its first

weapons-grade thermonuclear device in 1955. In the mid-1950's, the Soviets built the first submarines equipped with nuclear missiles. In 1957, they test-launched the first land-based intercontinental ballistic missile (ICBM). The first U.S. ICBM became operational in 1959. Also in 1959, the United States commissioned its first submarine equipped with SLBM's. The first MIRV's were acquired in the 1970's, first by the United States and then by the Soviet Union.

After the Cold War. Political developments in Eastern Europe and the Soviet Union from 1989 to 1992 ended the Cold War. Concern in Europe shifted from fear of massive conventional attack to ensuring political—and military—stability. World leaders began to focus on reducing nuclear arsenals and properly controlling them. Following the September 11 terrorist attacks in New York City and Washington, D.C., many nations began to perceive a new threat from terrorists who might gain access to nuclear arms, possibly with support from hostile countries. George W. S. Kuhn

Nuclear winter refers to the deadly worldwide environmental effects that could result from a major nuclear war. Such a war could bring on nuclear winter by drastically changing the earth's atmosphere and climate.

Nuclear winter could begin to develop from city fires created by the extreme heat of nuclear explosions. Large amounts of smoke from these fires could spread and cover at least half of the earth's surface. The smoke could prevent most sunlight from reaching the ground. Temperatures could drop substantially, and rainfall could be reduced. These conditions might last for several months or years. With greatly reduced sunlight, less rain, and lower temperatures, farming could stop, and worldwide famine could result. Nuclear winter also could reduce the earth's ozone layer, which protects people and other forms of life from the sun's dangerous ultraviolet light.

Scientists estimate that the nuclear explosions in a major nuclear war could kill 500 million people. But 4 billion more people could starve to death in the next year because of nuclear winter. Thus, nuclear winter could endanger every country. Mark A. Harwell

Nuer, *NOO uhr,* are a cattle-keeping people of northeast Africa. About 700,000 Nuer live in the grasslands and swamps along the Nile River in southern Sudan and western Ethiopia. They speak a language called Nuer, which belongs to the Nilo-Saharan family of African languages that also includes Dinka and Maasai.

Cattle play a central role in the social and religious life of the Nuer. A Nuer bridegroom gives a large gift of cattle to his bride's family. The Nuer sacrifice cattle to their supreme god and to lesser spirits. Milk and milk products make up much of their diet, but the Nuer do not kill their cattle for meat.

The Nuer move to higher ground during the rainy season, from May to December, when the Nile River floods. There they raise peanuts, a grain called *millet,* and other vegetable crops. The Nuer build houses of sun-dried mud and make thatched roofs for them.

The Nuer are divided into clans whose members have a common ancestor. Until the 1900's, the Nuer were not organized under the control of leaders. A religious expert called the *kuuarmuon* or *leopard-skin chief* helped settle disputes and presided over religious ceremonies. The United Kingdom and Egypt made Sudan a protectorate in 1899 and brought many changes to the Nuer, including the creation of tribal chiefs and administrato[rs.]

Arabic-speaking Muslims from northern Sudan have controlled Sudan's government since the nation gaine[d]

independence in 1956. In the 1980's, the Nuer joined other black African groups, including the Dinka, to form an opposition group called the Sudan People's Liberation Army (SPLA). Southern Sudan suffered brutal fighting and numerous famines as the SPLA battled for independence from the Muslim north. In the 1990's, the SPLA split into several ethnic divisions. The Nuer continue to fight the Sudanese government, which opposes granting independence to the south. Elliot Fratkin

Nuevo Laredo, *NWAY voh lah RAY doh* or *noo AY voh luh RAY doh* (pop. 310,227), is a city on the eastern part of Mexico's border with the United States. For location, see **Mexico** (political map). Three road bridges across the Rio Grande link the city with Laredo, Texas, which is located just north of the border.

Nuevo Laredo is a major point of entry into Mexico. It lies at the northern end of one of the stretches of the Pan American Highway, a major road to Mexico City.

© Bob Daemmerich, The Image Works

luevo Laredo lies on Mexico's border with the United States. his photograph shows a main business district of the city.

ach year, millions of American tourists visit the city. hey shop in handicraft stores; attend bullfights, dog aces, and horse races; and fish in a large lake nearby.

The city of Laredo was founded in 1755. It then included what are now Laredo and Nuevo Laredo. Laredo and uevo Laredo became separate cities in 1848, when the reaty of Guadalupe Hidalgo established the boundary etween Mexico and Texas. *Nuevo* in the name Nuevo aredo means *new.* Julian C. Bridges

ullification, *NUHL uh fuh KAY shuhn,* is the action of etting aside a law by declaring it *null and void.* The nited States Constitution does not provide any way for law of Congress to be declared unconstitutional after has been signed by the president. Some delegates to e Constitutional Convention believed that the courts ould naturally assume this authority. But only in 1803, ith the case of *Marbury v. Madison,* did the Supreme ourt of the United States flatly assert the right of the urts to pass on the constitutionality of an act of Coness.

The theory that the states, rather than any branch of the federal government, should have the right to *nullify* (declare unconstitutional) a law of Congress, developed slowly. The Kentucky and Virginia Resolutions of 1798 protested the Alien and Sedition Acts passed by Congress. Many people believed that these acts violated the First Amendment. They wanted all the states to declare the acts unconstitutional. But no other state would join in the action. In 1799, the Kentucky legislature stated its belief in the legality of nullification, but merely entered a protest against the Alien and Sedition Acts.

Nullification was next seriously proposed in 1828, when John C. Calhoun prepared a document known as the South Carolina Exposition. Rising industrial interests of the Northeast had persuaded Congress to include in the tariff law of 1828 (the "tariff of abominations") protective duties that the cotton-growing South disliked. Sentiment against the tariff was strongest in South Carolina. There was even talk of secession.

Calhoun's motive in recommending nullification was to provide an alternative to secession. He argued that the federal government had no right to judge the constitutionality of its acts. He also insisted that the states had given certain powers to Congress, and were alone competent to say whether or not Congress had exceeded its powers. Calhoun's reasoning was set forth by Senator Robert Y. Hayne in his famous debate with Senator Daniel Webster in 1830. Webster said nullification would break up the Union, and closed with the words: "Liberty *and* Union, now and forever, one and inseparable!"

In 1832, Congress again passed a protective tariff act. South Carolina passed an ordinance which declared the tariff laws of 1828 and 1832 null and void in that state. It threatened to leave the Union if the federal government tried to enforce the tariff laws anywhere in South Carolina. President Andrew Jackson warned the people that the laws would be enforced. He also took measures to make sure that the tariff would be collected at the important port of Charleston. After Congress passed a law called a *force bill* to uphold Jackson's position, it became clear that resistance was unwise. Besides, the Compromise Tariff of 1833, engineered through Congress by Henry Clay, greatly reduced the tariff duties.

Nullification was only one manifestation of the doctrine of states' rights, which, insofar as it meant the supremacy of the states over the nation, was ended by the American Civil War. Robert M. Weir

Numbat is an Australian marsupial with distinctive striped coloring. It grows about 10 inches (25 centimeters) long and has a bushy tail. The numbat is rusty-red above and white below. The hind third of the back is crossed by about six white stripes. A black stripe runs through the eye from snout to ear. Unlike most female marsupials, female numbats do not have a pouch for carrying their young. Instead, young numbats cling to their mother's body for the first few months of life.

Numbats feed during the day mainly on termites, which they catch by scratching open the insect's underground tunnels. The termites are caught on the numbat's long, sticky, cylindrical tongue. Numbats live in scrub woodland. They shelter at night in hollow logs. The numbat was once common over much of the south-

A numbat searches for termites on top of a termite mound. The numbat is a marsupial found only in the southwestern corner of Australia.

ern half of Australia but is now found only in the southwest corner.

Scientific classification. The numbat makes up the numbat family, Myrmecobiidae. It is *Myrmecobius fasciatus.*

Number, in grammar, is a feature of language that indicates how many persons or objects are referred to. In English, the form of a noun shows whether the reference is to one person, place, object, or idea, or to more than one. The form that indicates only one is called the *singular.* The form that indicates more than one is called the *plural.* Some other languages have a singular form, indicating one; a *dual* form, indicating two; and a plural form, indicating more than two. The plurals of English nouns are formed in *regular* and *irregular* ways.

Regular plurals are formed by adding *-s* or *-es* to the singular forms of the noun, as in *cap, caps* and *church, churches.* Compound nouns form plurals with the addition of *-s* or *-es,* but the placement varies. For example, the plural of *brother-in-law* is *brothers-in-law.* But the plural of *grown-up* is *grown-ups.* And in *manservant,* both parts take the plural form—*menservants.*

Irregular plurals are not formed according to any established rule, as are regular plurals. The plurals of some nouns of Old English origin are formed by a vowel change, as in *man, men* and *tooth, teeth.* A small number of nouns still have the Old English plural ending *-en*—for example, *ox, oxen* and *child, children.*

About a dozen nouns that end in *-f* or *-fe* are changed to *-ves* in the plural, among them *half, halves* and *wife, wives.* But not all nouns that end in *-f* or *-fe* follow this pattern. For example, *roof* and *chief* form regular plurals —*roofs* and *chiefs.*

Some nouns, such as *barracks, deer,* and *sheep,* have the same form in both the singular and the plural. A few expressions use a singular form even though a plural is actually called for. These include *two-inch nail, six-foot man,* and *two-gallon bucket.*

Some nouns, including *cowardice* and *brilliance,* have no plural. They differ from such nouns as *deer* and *sheep* because *two sheep* is correct, but *two cowardices* is not. The plural of *cowardice* would usually be expressed by saying something like *There are different kinds of cowardice.*

Foreign plurals. Words coming into English from foreign languages sometimes keep their foreign plurals. Such foreign plurals are mostly from Greek and Latin words. Some of these are *phenomenon, phenomena; criterion, criteria; alumnus, alumni; alumna, alumnae; fungus, fungi;* and *thesis, theses.* There is a strong tendency for such words to go into the regular English plural group. For example, at an earlier period the plural of *stadium* was the foreign form *stadia.* Now, however, *stadiums* is the plural form commonly used.

The spelling of plurals in English has many irregularities that are not reflected in speech. Singular nouns that end in *-y,* following a consonant, are changed to *-ies* in the plural—for example, *lady, ladies; flurry, flurries;* and *candy, candies.* For those ending in *-y,* preceded by a vowel, *-s* is added, as in *alley, alleys* and *day, days.* Some nouns that end in *-o* have *-s* added: *silos* and *pianos.* Others, for no special reason, have *-es* added: *tomatoes* and *heroes.* Several even have optional forms, such as *zeroes* or *zeros* and *ghettoes* or *ghettos.*

English pronouns also have plurals, but the relationship is not so consistent as in nouns. *We* can be called the plural of *I,* and *they* the plural of *he, she,* and *it.* *These* is the plural of *this,* and *those* the plural of *that.*

English verbs reflect number by agreeing with the subject. For example, the verb *play* occurs with a plural subject in the sentence *The boys play baseball every day.* The verb appears with a singular subject in *The boy plays baseball every day.* Patricia A. Moody

Number and numeral. A number is an idea that is used to refer to amounts of things. People use *number*

words, number gestures, and *number symbols.* Number words are said out loud. Number gestures are made with some part of the body, usually the hands. Number symbols are marked or written down. A number symbol is called a numeral. When we read a numeral out loud, we say the number word for that numeral. When we want to write a number, we can write the numeral or the word. For example, we say the word *five* and write the numeral *5* or the word *five.* The number is the idea we think of when we see the numeral or when we see or hear the word.

There are several kinds of numbers. *Cardinal numbers* tell how many things there are, as in "There are *five* people in my family." *Ordinal numbers* tell the position of something in an ordered set. For example, "I am *sixth* in line for lunch." *Denominate numbers* tell how many units of something there are, as in "I weigh *62* pounds." Denominate numbers are also called *measure numbers.* See **Denominate number.** Karen Connors Fuson

See also **Arabic numerals; Decimal system; Duodecimal system; Infinity; Numeration systems.**

Number theory is the branch of mathematics concerned with the properties of the natural numbers 1, 2, 3, 4, and so on. Number theory also deals with a type of natural numbers called *prime numbers.* A prime number, such as 2, 5, or 71, is a natural number that can be divided without a remainder only by itself and 1.

About 300 B.C., the Greek mathematician Euclid discussed prime numbers in his book *Elements.* He proved that there are infinitely many prime numbers. Euclid's *Elements* also stated a famous property of natural numbers called the *fundamental theorem of arithmetic.* This theorem states that every natural number can be written as a product of prime numbers in exactly one way.

The systematic study of number theory began with the work of the French mathematician Pierre de Fermat in the 1600's. A landmark book in number theory was *Disquisitiones Arithmeticae* (1801), by the German mathematician Carl Friedrich Gauss. It developed a comprehensive theory of natural numbers, including a proof of the fundamental theorem of arithmetic. Thomas Butts

See also **Fermat, Pierre de; Gauss, Carl Friedrich.**

Numbers, Book of, is the fourth book of the Bible. Its title, which comes from ancient Greek and Latin versions of the Bible, reflects parts of the book that describe the census, or *numbering,* of the Twelve Tribes of Israel. The Hebrew title *In the Wilderness* is perhaps more accurate because the book tells about the Israelites during their traditional 40 years of wandering in the wilderness after their departure from Egypt.

The Book of Numbers begins at Mount Sinai with God ordering the Israelite leader Moses to take a census of the Israelites. The book ends with the Israelites camped on the plains of Moab, an area east of the Jordan River, just before they entered Canaan. The book highlights the personal virtue of Moses as the leader of the difficult and rebellious Israelites. An assortment of religious material is interwoven with the main story, including stories that describe the priestly role of the Levites—one of the Twelve Tribes of Israel. Other passages give procedures for such religious rituals as purification rites and sacrificial offerings to God. Carol L. Meyers

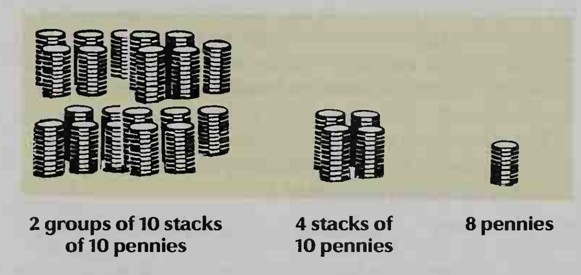
Numeral. See Number and numeral.

Numeration systems are ways of counting and of naming numbers. They are also called *numeral systems.* We cannot see or touch numbers, because they are ideas. But we can use symbols to stand for numbers. These symbols are called *numerals.* Here are four numerals that represent the number in a half dozen: 6, six, VI, and 𝍸 I.



The most commonly used numeration system has 10 basic numerals, called *digits:* 0, 1, 2, 3, 4, 5, 6, 7, 8, 9. With these symbols we can represent any number. This system is called a *decimal system* because it is based on 10. The word *decimal* comes from the Latin word for *ten.* Ten is the *base* or the *scale* of the decimal system.

Kinds of numeration systems

It is possible to use any whole number greater than one as a base in building a numeration system. The number of digits used is always equal to the base. For example, the decimal system, also called the *base 10 system,* uses 10 digits. The *binary system* that computers use, also known as the *base 2 system,* has only 2 digits.

The decimal system represents numbers in terms of groups of 10. Suppose you wanted to count the pennies you have saved. Instead of counting them one by one, you could count them in groups of 10. First, you would put them in stacks of 10. Then you would arrange the stacks in groups, putting 10 in each group, as shown.

How many pennies are there? You could count them like this: 2 groups of 10 stacks of 10 = $2 \times (10 \times 10)$ =

2 groups of 10 stacks of 10 pennies **4 stacks of 10 pennies** **8 pennies**

200; 4 stacks of 10 = $4 \times 10 = 40$; plus 8 single pennies. In all, you have $200 + 40 + 8 = 248$ pennies.

If you had counted the pennies one by one, you would have counted the same total. In decimal counting, you use one-digit numerals to count from 1 to 9. Then you use two-digit numerals to count from 10 to 99. In two-digit numerals, the digit on the left stands for the number of groups of 10. The digit on the right shows the number of ones. For example, the numeral 14 stands for 1 group of 10 plus 4 ones. After 99, you use three-digit numerals. The first digit on the left of these numerals stands for the number of *hundreds* (groups of 10 tens). Thus, the numeral 248 stands for 2 hundreds + 4 tens + 8, as shown in the illustration.

The value of each digit in a decimal numeral depends on its place in the numeral. Each position has a name that tells its value in terms of 10. In the numeral 248, the 8 is in the ones place; the 4 is in the tens place; and the 2 is in the hundreds place. In numerals with more than three digits, the additional positions are called the thousands place, the ten thousands place, and so on. Each position has a value 10 times greater than the position to its right.

Another way of expressing place value is to use *powers of 10.* The following table shows the meaning of several powers of 10.

Place name	Power of 10	Meaning	Symbol
Ones		1	10^0
Tens	1st	1×10	10^1
Hundreds	2nd	10×10	10^2
Thousands	3rd	$10 \times 10 \times 10$	10^3
Ten thousands	4th	$10 \times 10 \times 10 \times 10$	10^4

The 2 in 10^2, the 3 in 10^3, and the 4 in 10^4 are called *exponents.* The 10 is called the *base.* The exponent tells the number of times the base is to be used as a *factor.* For example, 10^2 means 10 is used as a factor twice, or 10×10; and 10^4 means $10 \times 10 \times 10 \times 10$.

The binary system groups numbers by twos and by powers of two. The word *binary* comes from a Latin word meaning *two at a time.* This system uses only two digits: 0 and 1. The numeral 10_{two} (one, zero, base two) stands for *two,* the base of the system. It means "1 two plus no ones."

In binary counting, single digits are used for *none* and *one.* Two-digit numerals are used for 10_{two} and 11_{two} (2 and 3 in decimal numerals). For the next counting number, 100_{two} (4 in decimal numerals), three digits are necessary. After 111_{two} (7 in decimal numerals), four-digit numerals are used until 1111_{two} (15 in decimal numerals) is reached, and so on.

In a binary numeral, every position has a value 2 times the value of the position to its right. For example, in the numeral 1010_{two}, the 0 on the right means 0×1; the 1 at the left of this 0 means 1×2; the next 0 means $0 \times 2 \times 2$; and the 1 at the far left of the numeral means $1 \times 2 \times 2 \times 2$.

The place value of each position can be expressed in terms of powers of 2. The following table shows the meaning of several powers of 2.

Base 2 numeral		Meaning		Decimal numerals	
1_{two}	=	1	=	1 =	2^0
10_{two}	=	2×1	=	2 =	2^1
100_{two}	=	2×2	=	4 =	2^2
$1{,}000_{two}$	=	$2 \times 2 \times 2$	=	8 =	2^3
$10{,}000_{two}$	=	$2 \times 2 \times 2 \times 2$	=	16 =	2^4

In the numeral 1010_{two}, the 0 at the right is in the ones place; the 1 next to it is in the 2^1 place; the next 0 to the left is in the 2^2 place; and the 1 at the far left is in the 2^3 place.

Working with numeration systems

The following examples of addition in the decimal and binary systems may help you understand the use of numerals in arithmetic.

Decimal addition. Such statements as $4 + 5 = 9$ and $3 + 4 = 7$ are called *arithmetic (AIR ihth MEHT ihk) facts.* We use many such facts in addition.

Decimal addition is a way of combining two or more groups into only one group. The principle of place value is used in adding ones to ones, tens to tens, and so on, as in the following example:

24	→	2 tens + 4 ones
+12	→	1 ten + 2 ones
36	←	3 tens + 6 ones

In this example, you use the addition fact $4 + 2 = 6$ and the fact $2 + 1 = 3$ (meaning 2 tens + 1 ten = 3 tens, or 30). Therefore, the sum is 3 tens plus 6, or 36. In some problems, the sum in one or more places is 10 or more. Then you must *regroup* the sum. Regrouping in addition is sometimes called *carrying.* The next problem shows how to regroup in decimal addition.

1		
48	→	4 tens + 8 ones
+25	→	2 tens + 5 ones
73	←	6 tens + 13 ones
		or, after regrouping,
		7 tens + 3 ones

In this problem, the ones add up to 13, which can be regrouped into 1 ten plus 3 ones. So you write 3 in the ones place and a small 1 in the tens place above the 4. Then you add the tens: $1 + 4 + 2 = 7$ tens, or 70. Therefore, the sum is 70 + 3, or 73.

Binary addition is based on only these facts:

$0 + 0 = 0$ $\quad 0 + 1 = 1$ $\quad 1 + 0 = 1$ $\quad 1 + 1 = 10$

Here is the way you use these facts to add 11 + 11:

Binary addition	Meaning	Decimal addition
1		
11	1 two + 1 one	3
+11	1 two + 1 one	+3
110	10 twos +10 ones	6
	or, after regrouping,	
	1 four +1 two + 0 ones	

First, you use the addition fact $1 + 1 = 10$ (meaning 1 two) to add the ones. Regroup 10_{two} into 1 two plus no ones. Write 0 in the ones place, and a small 1 above the twos column. Then add the twos: $1 + 1 = 10$; $10 + 1 = 11$. Write 1 in the twos place, and 1 in the fours place. Thus, $11_{two} + 11_{two} = 110_{two}$.

History

How numeration systems began. Ancient people had several ways of recording the few numbers they needed. A shepherd could collect pebbles to represent the number of sheep in a flock. Each pebble meant one sheep. A bag of pebbles stood for the whole flock.

Later, people developed other ways to record the number of possessions they owned. They tied knots in a leather thong or scratched tally marks (𝍸) on the side of a rock. They then matched the knots or marks against each item. Next, people began to use words to represent numbers. These words described "how many" and helped people match items mentally. For example, people used the word for "wings" to mean two objects. For five items, they used the word that meant "hand."

Finally, people began to count by arranging the names of numbers in a certain order. To count, they spoke or wrote the word that meant "one," next the word for "two," then the word for "three," and so on. In time, people in many parts of the world developed various counting systems. Some were based on 5, others on 10, and still others on 12 or 60. People still use such measures as 12 inches in a foot and 60 minutes in an hour, taken from these ancient systems.

In most early numeration systems, people formed numerals simply by repeating basic symbols and adding

their values to get the number they wanted. The Egyptians, Greeks, and Romans used numeral systems of this kind. The Maya of Central America and the Hindus of India used systems that followed the principle of place value and used a symbol that meant *not any.* The Hindu system became the decimal numeral system.

The Egyptian numeral system. About 3000 B.C., the ancient Egyptians used *hieroglyphics* (picture writing) to write numerals, as shown below.

1	Stroke
10	Arch
100	Coiled Rope
1,000	Lotus Flower
10,000	Finger
100,000	Tadpole

This system was based on 10. But it did not include a zero symbol, nor did it use the principle of place value. The Egyptians formed numerals by putting basic symbols together. For example, they wrote the numeral 1,326 like this:

The Babylonian numeral system used *cuneiform* (wedge-shaped) symbols. An early system of about 2100 B.C. was based on 60. In this system, a numeral contained groups of symbols. One group stood for the number of ones, the next group stood for 60's, the next for (60 × 60)'s, and so on.

The Greek numeral system. About 500 B.C., the Greeks developed a system based on 10. This system used a 27-letter Greek alphabet—the present-day 24-letter alphabet plus 3 letters no longer used. The first 9 letters stood for numbers, from 1 through 9. The next 9 letters stood for tens, from 10 through 90. The last 9 letters were symbols for hundreds, from 100 through 900.

The Roman numeral system uses letters as symbols for numbers. But the early Roman system of about 500 B.C. differed from the system we use today. For example, the ancient Romans wrote 4 as IIII and 9 as VIIII. They used the symbol ↆ for 50 and CIƆ for 1,000. Today, we usually use IV for 4, IX for 9, L for 50, and M for 1,000. The numerals VI, XV, and LX illustrate the *additive* principle. When the first of two symbols stands for a larger number than the second, you add the value of the first to the second to get the value of the combination. Thus, the Roman numeral VI represents 6, or 5 + 1; XV represents 15 as 10 + 5; and LX represents 50 + 10 = 60.

The numerals IV and IX illustrate the *subtractive* principle. When the first of two symbols stands for a smaller number than the second, you subtract the value of the first from that of the second to get the value of the combination. Thus, in the Roman numeral IV, you subtract 1 from 5 to get 4.

The Maya numeral system was based on 20. A dot represented the number one, and a bar represented five. The Maya system was a place-value system, and the Maya used a zero before A.D. 300. With these features, the Maya system could have become the basis of a modern, worldwide numeration system. But by the time the Italian navigator Christopher Columbus made his first voyage to America in A.D. 1492, the decimal system was already established in Europe and in the Arabic and Hindu lands of Asia.

The Hindu-Arabic numeral system. Hindu mathematicians of the 300's and 200's B.C. used a system based on 10. The Hindus had symbols for each number from one to nine. They had a name for each power of 10 and used these names when writing numerals. For example, Hindus wrote "1 sata, 3 dasan, 5" to represent the number we write as 135. They wrote "1 sata, 5" for the number we write as 105.

The Hindus gradually developed a way of eliminating place names. They invented the symbol *sunya* (meaning *empty*), which we call *zero.* With this symbol, they could write "105" instead of "1 sata, 5."

During the 700's, the Arabs learned Hindu arithmetic from writings of the Hindus and the Greeks. Then, in the 800's, a Persian mathematician wrote a book that was translated into Latin about 300 years later. This translation brought the Hindu-Arabic numerals into Europe.

Several centuries passed before the Hindu-Arabic system became widely used. After Europeans learned to print from movable type in the 1400's, they published many mathematics textbooks. Most of the books showed calculations using the Hindu-Arabic system. These books brought the system into widespread use.

The binary system. During the late 1600's, the German mathematician and philosopher Gottfried Wilhelm Leibniz developed the binary numeration system. However, mathematicians found no practical use for the system until the 1940's, when computers were developed.

Numerology, *NOO muh RAHL uh jee,* is the practice of using numbers to analyze character and foretell the future. It is based on the belief that the universe is governed by numerical laws and that each number has special powers and qualities. Most scientists believe that numerology has no scientific basis, but many people throughout the world practice it.

Numerologists believe that a person's name is an important clue to that person's character. Each letter in the name is changed to a number using a system based on ancient Greek and Hebrew alphabets. The numbers are added together and the separate figures in the total are combined to arrive at a number from one to nine. Suppose the numbers derived from a person's name total 75. The 75 is broken into a 7 and a 5, which add up to 12. The 12 is separated into a 1 and a 2, which total 3. This number supposedly reflects the person's character. For example, people with the number one are said to be

ambitious and forceful. Those with the number two supposedly are quiet and shy.

Another number that numerologists believe reveals character is the *birth number,* which is determined by adding the figures in a person's birth date. Numerologists also combine the birth number with the figures in any year to find a *personal year number.* This number predicts what is going to happen to the person in that year. Christopher McIntosh

See also **Fortunetelling.**

Numidia, *noo MIHD ee uh,* was an area in northern Africa during ancient times. It occupied part of what is now Algeria. Numidia was allied with nearby Carthage when the Second Punic War between Carthage and Rome began in 218 B.C. But Massinissa, a Numidian chieftain, sided with the Roman general Publius Cornelius Scipio. In return, as Scipio's ally, Massinissa was rewarded with territory and became king of all Numidia about 200 B.C. The next year, the Numidians helped Scipio defeat the Carthaginians, who were led by Hannibal, at Zama in northern Africa.

Several times after the war, Massinissa seized land from Carthage. Finally, Carthage fought back, helping bring about the Third Punic War (149-146 B.C.). Rome destroyed Carthage in the war but also halted Numidian expansion. By 112 B.C., Jugurtha, adopted grandson of Massinissa, had seized all of Numidia in defiance of Rome. He was defeated by the Roman general Marius in 106 B.C. In 46 B.C., Numidian King Juba I fought Julius Caesar and was defeated. Caesar annexed Numidia and made most of it a Roman province. Henry C. Boren

Numismatics. See **Coin collecting.**

Nun is a woman who belongs to a religious community and dedicates her life to carrying out its goals. Various major religions, including Buddhism, Christianity, and Taoism, have orders of nuns. The Roman Catholic Church has more of these orders than any other Christian denomination.

Most Roman Catholic orders of nuns have different requirements for permanent membership, but they all require years of preparation. When a woman enters an order, she begins a period of spiritual training called a *novitiate.* During this period, which in many orders lasts several years, she becomes thoroughly acquainted with the obligations of religious life (see **Religious life**). After her novitiate, the woman takes her first vows, and after several more years, final vows. She promises to give up possession of worldly goods, obey her superiors in the order, and remain unmarried. These promises may be either *simple vows* or *solemn vows.* Solemn vows are more binding.

A woman who has taken simple vows is known as a *sister.* One who has taken solemn vows is properly called a nun. But the term *sister* is commonly used as a form of address for a nun.

The first convents for women were founded in the Egyptian desert during the early 300's by Saint Pachomius. During the Middle Ages, nuns led strictly *cloistered* (secluded) lives in such convents. In 1633, Saint Vincent de Paul and Saint Louise de Marillac founded the Daughters of Charity (now often called the Sisters of Charity), an order devoted to charity work outside the convent. The members cared for orphans and the sick and taught children and adults.

The nun's way of life was modernized by Vatican Council II, a worldwide council of the Roman Catholic Church held from 1962 to 1965. Many orders now permit their members to live in small informal groups rather than in a convent. Many nuns no longer must wear the traditional robe and veil. Nuns continue to work in charitable and educational fields. They now also counsel youths in juvenile courts and perform other services as well. Anne E. Carr

Nunavut, *NOO nuh voot,* is a huge region in northeastern Canada that became a separate territory on April 1, 1999. On that date, Nunavut was carved out of the eastern part of Canada's Northwest Territories to provide more self-government for the Inuit, who make up most of the population. Nunavut means *Our Land* in Inuktitut, an Inuit language. Iqaluit is Nunavut's capital and largest town.

Nunavut is part of a vast subarctic region that has long, cold winters and short, cool summers. The territory is sparsely populated due to its harsh climate, but it has rich mineral deposits. The territory covers about 810,000 square miles (2.1 million square kilometers) and makes up about one-fifth of Canada's land area.

Land and resources

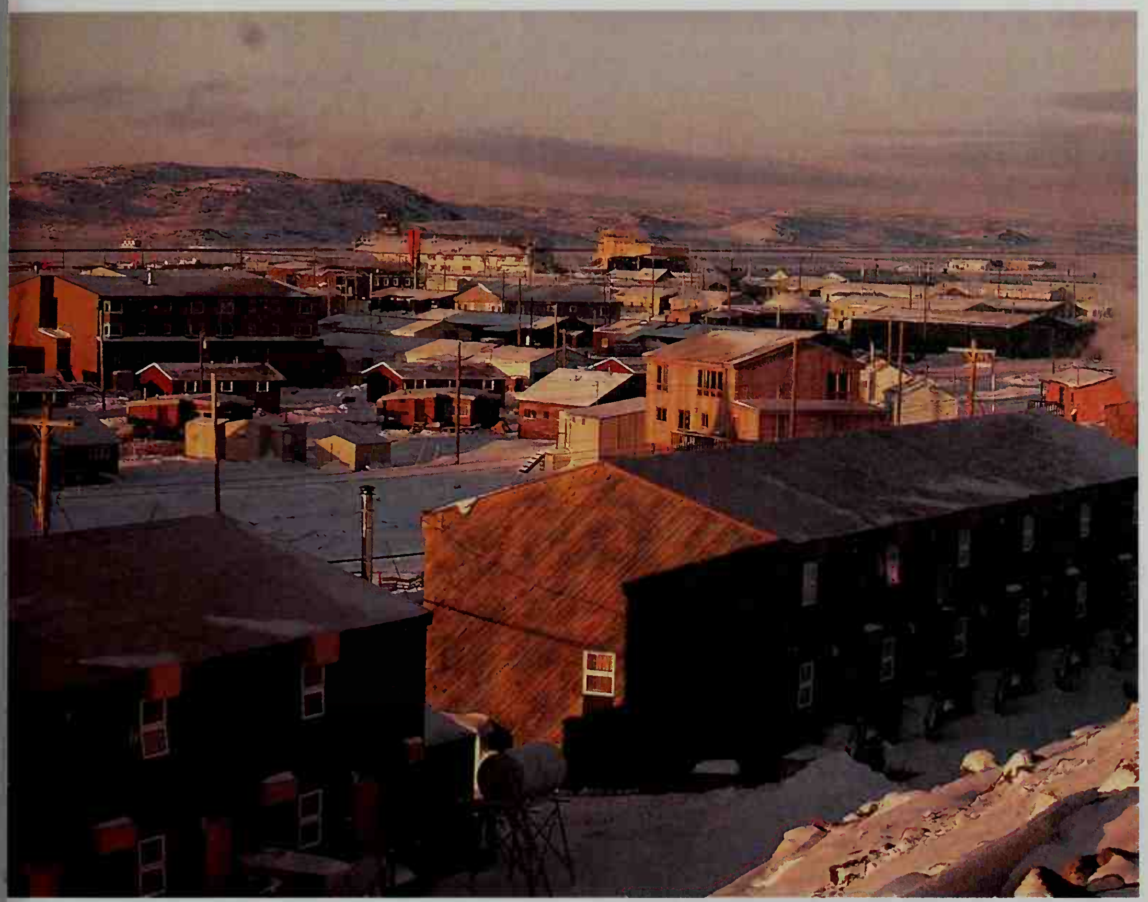
Location and description. Much of Nunavut lies north of the Arctic Circle. The territory is bordered on the south by the province of Manitoba, on the west by the Northwest Territories, and on the north by the Arctic Ocean. To the east lies Greenland, a province of Denmark, separated from Nunavut by Baffin Bay. Many of the islands north of the Canadian mainland are part of Nunavut. The territory's islands include Baffin, Ellesmere, and Southampton islands, all part of a region known as the Arctic Archipelago. Cape Columbia on Ellesmere Island is Canada's northernmost point.

Nunavut consists mainly of treeless, rocky, rugged terrain. Much of the ground beneath the surface is *permafrost* (permanently frozen ground). Some permafrost in Nunavut is more than 2,000 feet (600 meters) thick. Only the top 6 to 60 inches (15 to 150 centimeters) of ground thaws in the summer.

Glaciers cover parts of Baffin and Ellesmere islands. The two islands also have rugged mountains and deep *fiords* (long, narrow bays). Ellesmere Island has a high

Facts in brief

Capital: Iqaluit.



Government: *Parliament*—members of the Senate, 1; members of the House of Commons, 1. *Territorial*—members of the territorial Legislative Assembly, 19.

Area: 808,185 mi² (2,093,190 km²)

Elevation: *Highest*—Mount Barbeau in the United States Range, 8,584 ft (2,615 m) above sea level; *Lowest*—sea level along the coast.

Population: *2001 census*—26,745; density, 3 persons per 100 mi² (1 per 100 km²).

Chief products: *Fishing and hunting*—char, caribou. *Manufacturing*—fine arts and crafts. *Mining*—zinc, gold, lead.

© First Light

Iqaluit is Nunavut's capital and largest town. It stands on Baffin Island, on the shores of Frobisher Bay. Iqaluit had long been used as a seasonal Inuit fishing camp when Europeans arrived in the area in 1576. The town's name in Inuktitut, an Inuit language, means *place of fish.*

mountain range called the United States Range. The range's highest peak, Mount Barbeau, rises 8,584 feet (2,616 meters) above sea level.

Nunavut is home to a variety of wildlife. They include caribou, musk oxen, polar bears, wolves, Arctic foxes, and Arctic hares. Caribou have traditionally been important to the Inuit, providing them with food and clothing. Narwhals and other whales swim the icy waters of the Arctic Ocean. Seals and walruses also live there. Ravens, gyrfalcons, and ptarmigan live in Nunavut the year around. Many other birds, such as eider ducks and snowy owls, migrate to the region in the spring. Snow geese nest on Baffin Island.

Nunavut is rich in mineral resources. The territory has large deposits of copper, diamonds, gold, iron, lead, nickel, silver, uranium, and zinc. However, many of these resources have not been developed because of the region's harsh climate and the difficulty of transportation there. Several companies are also exploring for oil and natural gas in the region.

Climate. Nunavut has long, cold winters and short, cool summers. Average winter temperatures range from about −20 °F (−29 °C) in the southern part of Baffin Island to below −35 °F (−37 °C) on Ellesmere Island. Summer temperatures range from above 50 °F (10 °C) in southern Nunavut to about 36 °F (2 °C) in the north.

Nunavut has a dry climate. Nearly all of the territory receives less than 12 inches (300 millimeters) of precipitation a year. The northern part of the territory gets so little precipitation that it is often considered a polar desert.

People

Most of the people of Nunavut are Inuit. They live in dozens of small communities located mainly on the coasts. The largest populated place in Nunavut is the capital, Iqaluit. Most homes are provided by the Canadian government. Many residents play sports, and most hunt or fish for pleasure as well as for food. The territory has three official languages: an Inuit language called Inuktitut, English, and French.

Nunavut has a number of major social problems. For example, the territory has high rates of unemployment, suicide, and drug abuse.

Economy

Nunavut does not have a fully developed economy. The harsh climate and terrain and the great distances

Nunavut

WORLD BOOK maps

between places hinder access to the areas that are rich in natural resources. The Inuit are making the transition from subsistence hunting to a wage-earning economy, and the training of skilled workers is an important need.

The Nunavut government is the largest employer in the territory. The government has offices in a number of communities in addition to the capital, in part so that people throughout the territory will have access to government employment opportunities.

Mining contributes more to the economy of Nunavut than any other economic activity. The chief mined products include zinc, gold, and lead. Zinc and lead are mined on Baffin Island and Little Cornwallis Island. A gold mine operates at Contwoyto Lake, near Lupin.

The spectacular scenery of the region—mountains, fiords, and glaciers—and its rich array of wildlife attract many tourists to Nunavut. Inuit organizations and communities have begun to establish hotels, motels, outfitters, and guiding services for visitors. Tourists engage in such activities as hunting, fishing, kayaking, hiking, and exploring. Many people visit the territory's three national parks, Auyuittuq National Park on eastern Baffin Island, Quttinirpaaq National Park on northern Ellesmere Island, and Sirmilik National Park on Bylot Island and northern Baffin Island.

Traditional arts and crafts have long provided income for some Inuit. Galleries around the world sell Inuit soapstone carvings. Prints from Cape Dorset and Pangnirtung are famous. Inuit weavers produce tapestries at weaving centers in Pangnirtung and Clyde River.

The territory has a small fishing industry and a growing construction industry. Hunting and trapping also provide income for some residents.

Nunavut has few roads and no railroads. Airplanes provide the primary means of transportation between towns in the territory. There is regularly scheduled air service to almost all communities. Many people use snowmobiles to cover short distances. The use of modern-day telecommunications and information technologies, such as the Internet, has helped to overcome the problems of distance. All communities have radio and television, which are transmitted by a satellite relay system. Nearly all communities have telephone service.

Education

Nearly all Nunavut communities offer schooling through grade 12. Many Nunavut schools teach Inuktitut in the early grades, and English in the later years. Although the territory's literacy rate is lower than the national rate, an increasing number of students are attending and completing high school.

Nunavut Arctic College provides further education at its campuses in Iqaluit, Rankin Inlet, and Cambridge Bay. The college also has Community Learning Centres

located in every Nunavut community.

The territorial government is working to improve education in the territory. It hopes to reduce the size of classes, train and hire more Inuit teachers, and develop a curriculum that focuses more on Inuit language, culture, and history.

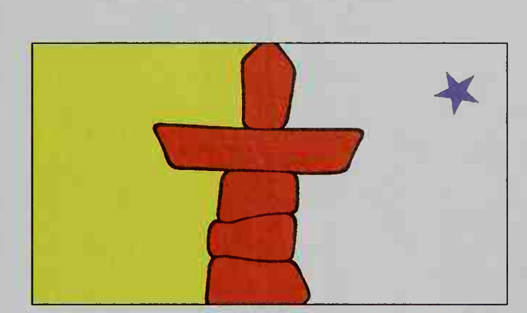
Government

Nunavut is one of Canada's three territories. The other two are the Northwest Territories and the Yukon Territory. The people of Nunavut elect one representative to the Canadian House of Commons. Nunavut has one representative in the Canadian Senate.

A premier heads the government with the assistance of an Executive Council (cabinet). Nunavut's Legislative Assembly elects the premier and the council members from among its own members. The council handles relations with the federal government and the provincial government.

The 19-member Assembly makes the laws for Nunavut. The voters elect members to five-year terms. The Assembly governs by *consensus*—that is, by general agreement. Nunavut has no political parties.

The territorial government has regional operations in 10 communities outside the capital. Local government is carried out by community groups called *hamlet councils.*

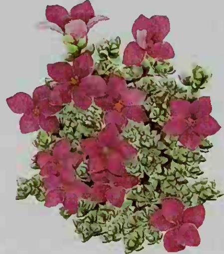


History

Early history. Ancestors of the Inuit have inhabited the Arctic for thousands of years. The pre-Dorset culture, the first Canadian Arctic culture, spread eastward from Alaska 4,000 years ago. About 3,000 years ago, a new culture called the Dorset spread rapidly across the Arctic. The Dorset people adapted well to life in the harsh Arctic climate. They made snow knives from bones and may have been the first to use the snowhouses called igloos. Their houses were heated by stone lamps fueled with animal fat.

About 1,500 to 1,000 years ago, another new culture, called the Thule *(THOO lee),* spread across the region, and the Dorset culture disappeared. The Thule people lived in villages in houses with stone floors and walls made from whale ribs or boulders covered with turf. The cornerstone of their culture was whaling. After the decline of whaling, these people hunted caribou and seals. The importance of villages then declined, and smaller groups lived in seasonal camps of tents and snowhouses. By about 1700, the Thule culture had become that of the modern Inuit.

Arrival of the Europeans. The Vikings were probably the first Europeans to visit Nunavut. They may have sighted its Arctic shores about A.D. 1000. About the 1500's, the riches of China encouraged many explorers to look for a Northwest Passage, a sea route through the



Symbols of Nunavut

The territorial flag

The territorial coat of arms

The floral emblem
Purple saxifrage

The territorial flag and the coat of arms bear representations of an *inuksuk*—that is, a traditional Inuit stone monument—and the North Star. On the coat of arms, the Inuit stone lamp next to the inuksuk symbolizes the warmth of family and community. An igloo and crown appear at the top, and a caribou and narwhal support the shield. The motto, written in Inuktitut, means *Nunavut Our Strength.*

Polar bears are among the rich variety of wildlife found in Nunavut. Other animals that make their homes in the territory include Arctic foxes, Arctic hares, caribou, musk oxen, and wolves.

North American continent to Asia. Martin Frobisher, an English seaman searching for the Northwest Passage, became the first known European to reach Nunavut. He arrived at Baffin Island in 1576.

In 1670, King Charles II of England granted part of Nunavut to the Hudson's Bay Company, a British fur-trading company. The company owned a vast area called Rupert's Land. In 1870, the Dominion of Canada acquired Rupert's Land. At the same time, it obtained from the United Kingdom a region called the North West Territory, which lay north, west, and south of Rupert's Land. The Canadian government organized these two new possessions into the North West Territories, later known as the Northwest Territories. The Canadian government became responsible for administering the Territories.

The Territories lost part of the Manitoba area in 1870, when Manitoba became a province. The Yukon Territory was cut off in 1898, and the provinces of Alberta and Saskatchewan in 1905. In 1912, Manitoba, Ontario, and Quebec acquired certain areas that had belonged to the Territories.

Establishment of Nunavut. For many years, the Inuit of the Northwest Territories had called for their own political unit in the east. They argued that their culture and language were distinct from those of the rest of the Northwest Territories. They also said that the territorial capital, Yellowknife, was too far from their own communities. Yellowknife stands near Great Slave Lake, some 1,500 miles (2,400 kilometers) to the west. In 1982, the people voted to divide the Territories into an eastern and a western territory. The federal government approved the division.

In 1992, the people of the Northwest Territories approved a boundary to divide the two territories. The Inuit territory would be called Nunavut. In 1993, the Canadian Parliament passed the Nunavut Land Claims Agreement Act, which gave the Inuit exclusive ownership of nearly one-fifth of Nunavut's land area, about 135,000 square miles (350,000 square kilometers). Parliament also passed the Nunavut Act, which approved the division of the Northwest Territories and the creation of Nunavut. Nunavut came into being on April 1, 1999.

Nuremberg, *NOO ruhm BEHRG* (pop. 465,255), is an industrial city in southern Germany. For location, see **Germany** (political map). The city's name is sometimes spelled *Nuremburg.* Its German name is Nürnberg. The Pegnitz River divides the central part of Nuremberg in half. A wall completed in the 1400's encircles the city's center. Allied bombing attacks during World War II (1939-1945) destroyed or damaged many of Nuremberg's historic buildings. The city's remaining landmarks include the medieval churches of St. Lawrence and St. Sebaldus, and the restored house of the famous artist Albrecht Dürer. Nuremberg's many industries include the production of automobiles, beer, bicycles, electrical equipment, office machinery, and toys.

Nuremberg's founding date is unknown, but the city dates from at least the 1000's. During the late Middle Ages, Nuremberg became a prosperous trade and cultural city. Nuremberg was a center of Nazi activities in the 1930's. In 1935, the Nazi-controlled German national assembly approved the anti-Jewish Nuremberg Laws, which were drafted in the city. The laws deprived Jews of citizenship and forbade "Aryan" Germans to marry Jews. Nuremberg was the site of Allied trials of Nazi war criminals (see **Nuremberg Trials**). Melvin Croan

Nuremberg Trials, *NOO ruhm BEHRG,* were 13 trials held to judge leaders of Germany for their actions during World War II (1939-1945). The trials took place from 1945 to 1949 in Nuremberg, Germany, where the Nazi Party had staged huge rallies. This party, led by dictator Adolf Hitler, ruled Germany during World War II.

Nazi leaders faced charges of committing aggressive acts and war crimes. These crimes included the murder of about 6 million Jews, known as the *Holocaust,* and about 5 million other Europeans. The Nuremberg Trials were the first war crimes trials conducted by the victors of a war in modern times. They were organized by the United States, the Soviet Union, the United Kingdom, and France.

The trials. The Nazi leaders were charged with crimes in four major areas—conspiracy to commit crimes against peace, crimes against peace, war crimes, and crimes against humanity. Conspiracy to commit crimes against peace included the planning of a war of aggression. The crimes against peace included carrying out a war of aggression. War crimes covered such acts as the murder of prisoners of war and of civilians, and the excessive destruction of land and cities. Crimes against humanity referred to three main offenses: (1) deporting civilians and using them for slave labor, (2) conducting inhumane medical experiments, and (3) perse-

uting and murdering people because of political be-
efs, race, or religion.

A group called the International Military Tribunal con-
lucted the first trial. This trial ran from November 1945
o October 1946. It had eight judges, two each from the
Jnited States, Britain, France, and the Soviet Union.
wenty-two people were tried. They included such chief
Jazi Party advisers and diplomats as Hermann Goering,
lbert Speer, Rudolf Hess, Joachim von Ribbentrop, and
Aartin Bormann. Military leaders who were charged in-
luded Grand Admiral Karl Doenitz and Colonel General
lfred Jodl. Hitler and two of his chief aides, Joseph
Goebbels and Heinrich Himmler, committed suicide or
ad themselves killed before the trials.

The judges convicted 19 defendants. Twelve of them,
ncluding Bormann, Goering, von Ribbentrop, and Jodl,
eceived death sentences. Ten were hanged on Oct. 16,
946. Goering committed suicide a few hours before.
Bormann's whereabouts were unknown at the time, and
e was tried *in absentia* (while absent). Hess, Doenitz,
nd five others received prison sentences ranging from
0 years to life in Spandau Prison in Berlin.

Twelve more trials took place at Nuremberg from
946 to 1949. They were conducted by U.S. judges. They
nvolved 185 defendants, including Nazi Party officials,
udges, business executives, and doctors. More than half
vere sentenced to prison, some received death sen-
ences, and others were found not guilty.

Reaction. The Nuremberg Trials aroused consider-
ble controversy. Some observers considered a number
f the sentences too harsh. Other critics have pointed
ut that the victorious nations committed some of the
ame types of acts for which the Nazis were tried. Also,
he Nazis on trial were not allowed to use this argument
n their defense.

Nevertheless, the Nuremberg Trials have had far-
eaching effects. They carefully documented the Holo-
caust and other Nazi crimes. The trials also rejected the
rgument that orders from superiors relieve people
rom responsibility for war crimes. Thus, the Nuremberg
Trials emphasized the idea that soldiers and citizens
ave a moral duty to disobey inhumane orders or laws.

Nureyev, *nu RAY yuhf,* **Rudolf** (1938-1993), was one of
he great ballet dancers of the 1900's. He became known
or his exciting stage personality and his strong, expres-
sive dance technique. Nureyev danced more than 100
roles. In 1962, he began a partnership with the famous
English ballerina Dame Margot Fonteyn. Nureyev and
Fonteyn performed together in such ballets as *Giselle,*
Swan Lake, and *Les Sylphides.* As a *choreographer* (cre-
ator of dances), Nureyev created versions of such ballets
as *Don Quixote* and *The Nutcracker.*

Nureyev was born on March 17, 1938, near Irkutsk, in
Russia. He joined the Kirov Ballet in 1958 and soon be-
came its principal dancer. In 1961, Nureyev defected to
he West while the Kirov Ballet was performing in Paris.

© Martha Swope

Rudolf Nureyev became one of the most famous ballet dancers of the 1900's. He won praise for his exciting stage personality and powerful leaps in such ballets as *Swan Lake, shown here.*

He then danced with ballet and modern dance compa-
nies throughout the Western world and appeared in
several dance films. He was director of the Paris Opera
Ballet from 1983 until 1989. Katy Matheson

Nurmi, *NUR mee,* **Paavo,** *PAH vaw* (1897-1973), a
Finnish athlete, is considered the greatest distance run-
ner in track and field history. His achievements from
1920 to 1932 made him a national hero of Finland. Dur-
ing that period, Nurmi set 29 world records in distances
from 1,500 meters to 20,000 meters. He also won 9 gold
medals in the Olympic Games of 1920, 1924, and 1928. At
the 1924 Games, he won 5 gold medals, a record in track
and field. Over his career, he won 12 Olympic medals in
7 events, including gold medals in 6 events. Both
achievements also represent Olympic records in track
and field.

Paavo Johannes Nurmi was born on June 11, 1897, in
Turku, Finland. He was the first distance runner to scien-
tifically plan his races. For example, he used a stop
watch to help run at a desired pace. His Olympic career
was cut short just before the 1932 games. The Interna-
tional Amateur Athletic Federation declared that he had
accepted too much money for expenses during a Euro-
pean tour, making him a professional athlete and there-
fore ineligible for the Olympics. Michael Takaha

Nurse. See Nursing.

Nursery produces and raises plants for transplanting
in fields, gardens, orchards, and landscaped areas. Nurs-
eries in the United States raise trees, shrubs, ground
covers, and other plants, including flowers and vegeta-
bles. Some nurseries produce tropical plants.

Most nurseries are commercial operations. Certain
agencies of the federal and state governments operate
nurseries to reforest public lands.

Nurseries produce plants from seeds or cuttings,

or by grafting buds or stems from mature plants onto roots. In addition, certain plants are grown from bulbs or other plant structures. Nursery workers care for the plants by fertilizing and irrigating the soil, and by protecting them from disease, insects, and weeds.

Many nursery plants are *container-grown* and are sold in their containers. Some *field-grown* plants are sold *balled and burlapped*—that is, with their roots and soil wrapped in burlap. Others are sold *bare-root* with their roots packed in moist material to prevent drying.

There are three kinds of commercial nurseries. *Wholesale nurseries* sell to other nurseries and handle large quantities of a small variety of plants. *Retail nurseries* sell directly to the public. They handle relatively small quantities of many kinds of plants. Most retail nurseries operate along busy highways, where they can be reached easily. Some provide planting and maintenance service and also offer planting designs for home gardens and yards. *Mail order nurseries* distribute catalogs that describe the plants they sell. Many of these nurseries grow only a small portion of their plants. They buy the rest from wholesale nurseries. The major nursery association in the United States is the American Association of Nurserymen. The association is headquartered in Washington, D.C. Jules Janick

Nursery rhyme is a rhythmical poem that amuses or soothes young children. Many nursery rhymes also pass along cultural information and values. These poems are a vital form of folk literature. They appeal to children because of their pleasing rhymes and sounds and compelling rhythms. Youngsters often keep time with the musical rhythm of the words by clapping their hands or rocking back and forth. Nursery rhymes help children appreciate the many sounds and rhythms of a language.

The great variety of stories and characters in the verses stimulates the imagination. Children delight in the humor and surprises in such rhymes as "Mary Had a Little Lamb" and "Hey Diddle Diddle." Other rhymes, including "Three Little Kittens" and "Old Mother Hubbard," introduce children to their first stories. A child's familiarity with nursery rhymes can lead to a lasting appreciation of poetry and prose.

Types

The most popular types of nursery rhymes include (1) lullabies, (2) singing game rhymes, (3) nonsense rhymes, (4) rhyming riddles, (5) counting-out rhymes, (6) tongue twisters, (7) verse stories, and (8) cumulative rhymes.

Lullabies are simple, soothing melodies sung to children to help them fall asleep. "Rock-a-bye Baby" is probably the best-known lullaby in the English language.

Rock-a-bye, baby, on the tree top,
When the wind blows the cradle will rock;
When the bough breaks the cradle will fall,
Down will come baby, cradle, and all.

Singing game rhymes accompany dances or certain games. For example, "Ring-a-Ring O'Roses" is sung by a group of children who join hands and dance in a circle.

Ring-a-ring o'roses,
A pocket full of posies,
A-tishoo! A-tishoo!
We all fall down.

Nonsense rhymes provide a verbal release from the "sensible" requirements of everyday life. This one has the humor and wit typical of such verses.

I eat my peas with honey,
I've done it all my life.
It makes the peas taste funny,
But it keeps them on the knife.

Rhyming riddles ask children to unravel a mystery or identify a certain object from clues in the verse.

Runs all day and never walks,
Often murmurs, never talks;
It has a bed and never sleeps;
It has a mouth and never eats.

The answer is a *river*.

Counting-out rhymes provide formulas that help children choose sides for games. The verse "One, Two, Three, Four, Five" is an example.

One, two, three, four, five!
I caught a hare alive;
Six, seven, eight, nine, ten!
I let her go again.

Such rhymes may also help children learn the days of the week, the months of the year, and how to count.

Tongue twisters are difficult to say without making a mistake. The playful challenge of these rhymes comes from reciting them accurately as fast as possible, as in the famous tongue twister "Peter Piper."

Peter Piper picked a peck of pickled peppers;
A peck of pickled peppers Peter Piper picked;
If Peter Piper picked a peck of pickled peppers,
Where's the peck of pickled peppers Peter Piper picked?

Verse stories are short dramatic tales that often are longer than other types of nursery rhymes. "The Queen of Hearts" is a popular verse story.

The Queen of Hearts,
She made some tarts,
All on a summer's day;
The Knave of Hearts,
He stole those tarts,
And took them clean away.
The King of Hearts
Called for the tarts,
And beat the knave full sore;
The Knave of Hearts
Brought back the tarts,
And vowed he'd steal no more.

Cumulative rhymes, in each successive verse, repeat the information presented in the earlier verses. Thus, each verse is longer than the previous one. Here is the first verse of "The House That Jack Built."

This is the house that Jack built.

The second verse has two lines.

This is the malt
That lay in the house that Jack built.

The third verse adds another line to the story.

This is the rat
That ate the malt
That lay in the house that Jack built.

This cumulative rhyme then continues for many more erses.

History

For centuries, nursery rhymes have been passed ›rally from generation to generation. Every culture has :s own nursery rhymes, plus additional ones that have ›een adopted from other societies. The verses have a vide variety of origins. Some nursery rhymes are fragnents of ballads, prayers, proverbs, or tavern songs.)thers came from ancient customs or rituals. Still ›thers, such as "Old King Cole" and "Hey Diddle Diddle," nay have been based on real people and events. Many ›ursery rhymes developed a number of versions as they ›assed orally from generation to generation.

Most nursery rhymes probably originated after 1600, ›ut some rhymes may have been created earlier, such ›s "Little Tom Tucker." One of the earliest English collecions of nursery rhymes, *Mother Goose's Melody,* was ›rought out in 1781 by an English publisher. This collecion was reprinted in 1786 by an American publisher, saiah Thomas.

Many nursery rhymes that date from before 1800 vere intended to entertain adults, not children. The hymes that were written especially for youngsters in:luded alphabet rhymes, lullabies, and verses that were ›sed in games.

The term *nursery rhyme* first appeared in print in 1824 n *Blackwoods's Edinburgh Magazine,* a Scottish periodi:al. Before then, the rhymes were known as songs or ditties. James Halliwell, a British author, compiled the first large-scale collections of nursery rhymes, called *The Nursery Rhymes of England* (1842) and *Popular Rhymes and Nursery Tales* (1849). These books served as the basis of nursery rhyme collections in English until the publication in 1951 of *The Oxford Dictionary of Nursery Rhymes.* This work was edited by Iona and Peter Opie, a husband-and-wife team of British scholars.

Nursery rhymes are short poems for children. This picture illustrates the nursery rhyme "Peter, Peter, Pumpkin-Eater," which ells about a man who keeps his wife in a pumpkin shell.

Nursery school is a type of early childhood education program designed chiefly for children 3 or 4 years old. Nursery school helps children develop their intellectual and physical skills and learn to get along with others. In addition, the school helps them develop good health and safety habits and encourages independence. The youngsters learn through a variety of play activities supervised by teachers. Nursery schools are sometimes called *preschool programs* or *prekindergarten programs.*

Nursery schools may be privately owned and operated, or publicly owned and supported by the government. Some privately owned nursery schools are operated by community or church groups. Others are run by individuals or corporations for profit. A few private nursery schools are *parent-cooperative schools,* which are owned and operated by parents. The parents hire a teacher, and perhaps a teacher aide, and take turns doing the other work of the school themselves. The number of nursery schools supported by government funding is increasing. Many are part of public-school systems. Most government-supported nursery schools serve children from low-income families or children with special needs, such as youngsters with disabilities.

Nursery schools differ from *day-care centers,* also called *child care centers,* which enroll older children—and sometimes infants—as well as 3- and 4-year-olds. Day-care centers chiefly care for children whose parents work. See **Day care.**

Nursery school instruction

Teaching methods in nursery schools differ from those of elementary and high schools. The children in nursery schools spend most of their time playing or in activities they have chosen instead of doing work assigned by the teacher.

The classroom of a nursery school also looks different. Instead of rows of chairs and desks, the room has areas called activity centers. Each center has different equipment and materials for the children to use.

Learning through play. A nursery school features long periods of play because young children learn best by playing. Preschool youngsters cannot grasp the meaning of words that represent unfamiliar objects or situations. As a result, these children learn better by direct contact with objects and other experiences than by using words alone. Nursery school children learn the

names, characteristics, and uses of things with which they play. The youngsters handle objects, compare them, count them, and move them around. These activities help children understand directions, distances, numbers, shapes, and sizes.

Nursery school children also develop social skills through play. They learn to cooperate with others, to share, and to resolve difficulties in a friendly way. The children also learn to express ideas and to listen to the ideas of others. As children play, teachers may make suggestions to encourage more complex play or may demonstrate problem-solving activities. Teachers ask questions to focus a child's attention on important aspects of the activities.

A number of nursery schools use a teaching technique developed by the Italian educator Maria Montessori. The *Montessori method* involves special learning activities that children choose for themselves and work with individually. See **Montessori method.**

A nursery school day provides a balance of active and quiet experiences. The children begin a typical day with an indoor activity period. During this period, they work alone or in groups at activity centers, and the teachers give individual help. Examples of activities include building with blocks or experimenting with objects in a large basin of water. Some children may pretend to be parents, police officers, or other adults. Other children draw, paint, or work with clay. Still others look at picture books or listen to recordings of stories or songs. Children may participate in a variety of activities in a day.

After the indoor activity, the teacher and teacher aide help the children clean up the classroom and put away their materials. The class might then have a snack. Next, the children might sit on the floor or on low chairs and talk with the teacher. They might chat about recent experiences or about an object that the teacher or a child has brought to school, or they may listen to a story. The class might also discuss plans for the rest of the day.

Most nursery schools also have an outdoor activity period, which helps youngsters develop strength and coordination by climbing, jumping, running, and other forms of exercise. The outdoor area might have boards, boxes, and large, movable wooden or plastic shapes that can be built into ramps, enclosures, or structures and combined in different ways for play. Most schools have sandboxes, tricycles, wagons, swings, and a structure for climbing.

The day might end with a music and movement period, during which the children sing, dance, or move to rhythm. When they are ready to go home, they often take samples of their artwork.

The nursery school teacher

The teacher's role is to provide education, care, and affection. The children receive some education directly, as when the teacher gives them information or tells stories. Other education comes indirectly, such as the creation of a learning opportunity that children can use on their own. Nursery school children are so young that the teacher must provide physical care. The teacher must also establish a warm relationship with the children and help them feel good about themselves. Youngsters need much individual attention as well.

A person who wants to be a nursery school teacher should like and respect children from all backgrounds. A teacher needs to be intelligent, well educated, and able to relate warmly to young children. The teacher should understand how children develop and how to help them learn. He or she must know how to work with parents and other adults for the welfare of children.

Opportunities and training. The number of nursery schools has increased greatly since the late 1960's. Jobs for teachers are available, though many of these positions involve low salaries. Women far outnumber men as nursery school teachers, but more and more men are entering the field.

Many people prepare for a career in nursery education by studying early childhood education or child development. Most colleges and universities offer four-year programs and many community and junior colleges offer two-year programs. The programs include courses in teaching methods, the history of early childhood education, and practice-teaching. In practice-teaching, a student actually teaches in a classroom under the guidance of an experienced teacher.

History

Institutions similar to nursery schools were established during the 1800's under the name infant schools. In the early 1900's, two British sisters named Margaret and Rachel McMillan set up one of the first institutions called a nursery school. Their school, located in a slum area of London, was designed to give children of poor families the benefits that wealthy children received in home nurseries.

Nursery schools spread to the United States by the 1920's. Many colleges and universities established laboratory nursery schools. At these schools, faculty and students studied young children and tested teaching methods in addition to educating the youngsters.

During the Great Depression of the 1930's, the United States government supported nursery schools under a program called the Works Progress Administration (WPA). The WPA nursery schools provided work for many teachers who had lost their jobs during the depression.

The greatest expansion of nursery school education occurred during the 1960's, when the government established a program called Head Start. Head Start was designed to help children of low-income families prepare for school. Today, it also serves children with disabilities. It provides children with medical, nutritional, and social services as well as education.

Nursery schools in the United States

In all states of the United States, a state agency licenses and regulates nursery schools. Some states only require nursery schools to meet fire, health, and safety regulations to obtain a license, while other states have stricter standards

Some states require a nursery school teacher to have a bachelor's degree in early childhood education, plus a teaching certificate. Other states require little more than a high school education. Teacher aides, also called teacher assistants, do not need a certificate. The teacher aides help teachers with such tasks as caring for school materials and providing individual help for the children.

urse's aide is a person who helps nurses in hospitals erform their work. A nurse's aide is also sometimes alled a *ward helper,* a *hospital attendant,* or a *nursing ide.*

The nurse's aide does as much of a nurse's work as ossible. By doing the jobs that require little or no train-ng, the nurse's aide allows a regular nurse to concen-rate on jobs that require special skills. Nurse's aides an-wer patients' calls; help feed, wash, and care for them; nd keep their rooms in order. If patients have to go to ome other part of the hospital, nurse's aides may go long. They may help support patients during treatment, r help move them onto or off beds and stretchers. In arger hospitals, nurse's aides may act as diet assistants r as clerks.

There are two kinds of nurse's aides. The Red Cross rains volunteer workers who help out in community ospitals. Many of these volunteers are older women. ut many nurse's aides are paid workers who have no raining in the field of nursing. Many young people ork as nurse's aides in a hospital for a while to find out hether or not they want to become nurses.

Pamela J. Maraldo

See also Nursing.

ursing. Most nurses work in hospitals taking care of ick people and helping them get well. But nurses also work in other places. Visiting nurses go to the homes of the sick. Some nurses assist in the offices of doctors and dentists. Others work in medical clinics, in schools, in stores and factories, in the armed forces, and on ships, trains, and airplanes. Nurses may be found wherever their skills are needed—in big cities, small towns, and farm areas in all parts of the world.

In addition to caring for the sick, nurses help healthy people stay well. They teach children and adults to protect themselves from disease. Nurses who have had advanced education may also teach in schools and colleges of nursing. Some nurses with advanced clinical skills have started their own clinics, providing patients with such services as physical examinations and nutrition and mental health counseling.

The two main groups of nurses are *professional nurses* and *technical nurses.* Professional nurses are usually graduates of four- or five-year college programs. Technical nurses are graduates of two-year community college or three-year hospital programs. Another group of nurses, called *practical nurses,* complete a training program that generally lasts 12 months. Practical nurses perform many duties that relieve professional and technical nurses for other tasks that require more preparation.

Most nurses are women. More women serve in the field of nursing than in any other profession except teaching. However, more and more men have been entering the nursing profession. Until the 1960's, men made up only 1 percent of the total number of professional nurses. By the early 2000's, men made up over 10 percent of students enrolled in undergraduate professional programs and about 5 percent of all practicing professional nurses.

Professional and technical nurses

Hospital nurses. Most professional and technical nurses work in hospitals. They work with doctors and other medical personnel in caring for patients. Nurses function in a great variety of roles in the hospital. They work as members of the surgical team in the operating room. They work on *intravenous therapy* teams giving blood transfusions or injections of drugs. Nurses help patients learn to function with disabilities or illness and provide important information to assist patients when they are discharged from the hospital. Nurses also care for newborn babies.

Nurses manage the daily care of patients. They see that patients have a daily bath and that they eat proper foods. They make sure that patients do exercises or have treatments that will aid in recovery. Nurses administer prescribed medicines to patients and teach patients to care for themselves. Nurses keep a watchful eye on patients and keep track of any changes in physical condition, mental attitude, or reaction to drugs or other treatment.

The well-being of patients is of first importance to nurses. They take time to reassure worried patients and boost the patients' morale. Nurses are taught to recognize and understand patients' needs and to provide emotional support as well as physical care. For example, they take time to play with a child, read to a person who cannot see, or write letters for a patient who has a broken arm.

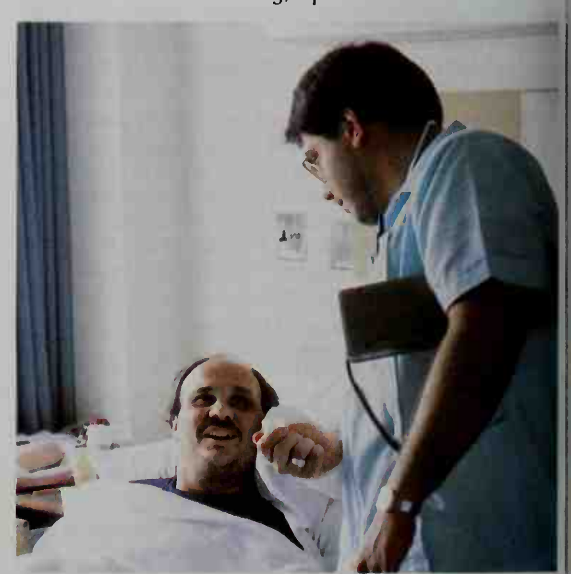
WORLD BOOK photo by Dan Miller

Most nurses work in hospitals, where they help comfort and care for people who are sick, injured, or recovering from surgery. This nurse is taking a patient's blood pressure.

A *nurse manager* has charge of the nurses and patients in a unit or in a section of the hospital. With additional education, a nurse may become a supervisor and direct several units or may specialize in one kind of nursing. For example, a *neonatal clinician* is a nurse who specializes in the care of newborn babies. A *cardiovascular specialist* specializes in caring for heart patients. Specialization requires a master's degree, which also prepares a nurse for teaching, supervision, or administration.

In other institutions, such as nursing homes and mental hospitals, nurses perform in much the same way as hospital nurses. Specialized knowledge or training usually is required because of the special needs of the patients.

Private-duty nurses work in hospitals or in private homes. Unlike other nurses, they are employed by the patient rather than by the hospital. Private-duty nurses may devote all their time to only one patient who needs constant care. Sometimes they may care for a small group of patients. Most hospitals keep a *registry,* or file, of nurses who are available for private duty.



Community health nurses. Community health offers increasing opportunities for nurses. Those who wish to enter this field must take special college courses that are approved for community health work. Community health nurses usually help take care of large groups of people in their homes and communities. Most of these nurses work for government or private agencies.

Visiting nurses are community health nurses. So are the nurses employed by city, county, or state health departments. Community health nurses may go into homes to care for patients who have just returned from hospitals. They often teach patients with chronic illnesses, such as cancer and diabetes, how to care for themselves. They also teach patients and their families about proper diet, personal cleanliness, and other ways of preventing illness. Community health nurses may take part in many community projects, such as polio-vaccination and immunization programs for communicable diseases. Some of them work in schools and summer camps.

Occupational, or industrial, health nurses work in factories, stores, banks, and many business offices. These nurses give first aid to the injured. They give employees physical examinations, screen them for illnesses, and treat them for colds, bruises, and other minor ailments. They also promote programs to prevent accidents on the job.

Nurse practitioners are nurses who have had additional training in a certain area of specialized practice. For example, some nurse practitioners specialize in *geriatrics* (caring for the aged) and others in *pediatrics* (caring for children). Nurse practitioners perform many functions that were once done only by physicians. These nurses give physical examinations, diagnose and treat minor illnesses, and advise patients on health problems. By administering much of the daily health care, nurse practitioners free physicians to treat patients suffering more acute ailments. Most nurse practitioners work in private clinics or doctors' offices, or in a group practice with physicians or other nurse practitioners.

Other nursing careers. Many professional nurses combine the professions of teaching and nursing. To teach in a school of nursing, a professional nurse must

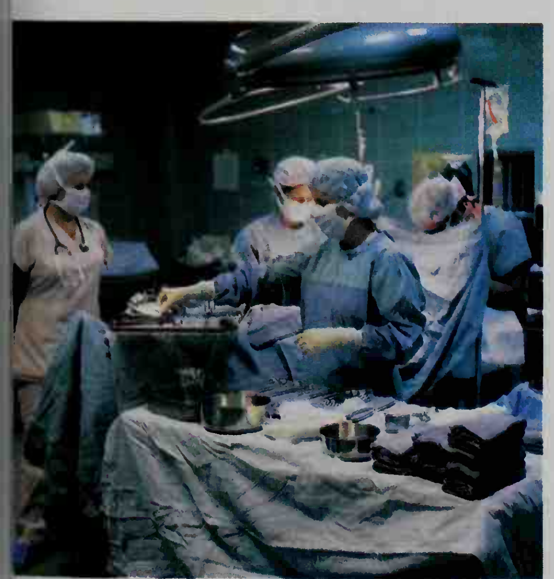
ave advanced college preparation. A doctoral degree
ı nursing is usually required for teaching.

Professional and technical nurses may work in clinics r in doctors' and dentists' offices. Many nurses work as *urse researchers.* They conduct research on how to re-eve patient suffering. For example, nursing research as discovered how to decrease vomiting in patients ho undergo *chemotherapy* (treatment with drugs). ome nurses hold positions in nursing organizations. thers write books and articles about nursing. Compa-es that manufacture drugs and medical equipment ften employ nurses as consultants on their products. urses serve in the Army, Navy, and Air Force. Other ranches of the government, such as the Department of tate and the Department of Veterans Affairs, have urses on their staffs.



Practical nurses

Practical nurses are specially educated men and omen who help professional and technical nurses. ney may work in hospitals, private homes, nursing omes, public health agencies, and doctors' offices. actical nurses often care for mothers and babies, the ged, and chronically ill people. Frequently they are re-ponsible for such tasks as making beds, giving baths, d feeding the helpless.

Nursing as a career

Nursing offers daily satisfaction to those who have a enuine desire to help others. It also provides such a ide range of job opportunities that a capable nurse—specially one with an advanced degree—can always be re of a job.

Among the rewards of nursing are the challenges it fers. A badly injured person may need immediate and pert care. Medicines and equipment must be rushed the patient's bedside. The family must be comforted, and the doctor must be given a detailed report on the patient's condition. A nurse's greatest reward often is the knowledge that his or her skill has helped to relieve suffering or to save a life.

WORLD BOOK photo by Dan Miller

perating room nurses assist surgeons during operations. ese nurses must react instantly and accurately to the sur-ons' requests for operating instruments.

People planning a career in nursing should also consider a number of other factors. Advances are being made steadily in nurses' salaries. Nurses must be active and on their feet a great deal and may have to do some strenuous work, such as lifting patients. Special *body mechanics* courses taught in nursing schools help the nurse prepare for such activities.

A nurse must like people and want to help them and must also have self-reliance and good judgment. Patience, tact, honesty, responsibility, and ability to work easily with others are valuable traits. Good health is another "must."

Most professional or technical nursing schools accept only candidates who rank in the upper half or upper third of their high-school graduating classes. Entrance requirements for practical nursing are less exacting. High-school graduates are preferred, but many practical nursing schools accept candidates with two years of high-school work or less.

Costs of a nursing education program vary widely. Most hospital schools require an entrance fee and charge tuition. In most college schools of nursing, students pay tuition. They also pay for all or part of their maintenance. People who want to enter nursing should inquire about costs at the schools that they are considering attending.

Professional and technical nursing education. Three types of programs provide the necessary training for a career in professional and technical nursing. They are (1) associate degree programs, (2) diploma programs, and (3) baccalaureate programs. The time needed to complete a program ranges from two to five years, depending on the type of program.

Associate degree programs consist of a two-year course of study in nursing care and related subjects. These programs lead to an associate degree in nursing. Many junior and community colleges offer such programs. Students also gain practical experience by working in local hospitals and other health agencies that cooperate in the programs.

Diploma programs are offered by hospital schools. They require two or three years of study, after which the student receives a diploma. Students take nursing courses in classrooms and laboratories, and they work with patients in the hospital and at health agencies.

Baccalaureate programs offered by colleges and universities lead to a bachelor of science degree. The course work requires four to five years. It includes experience with patients in hospitals and health agencies as well as courses in nursing and in the humanities.

All nursing education programs provide both classroom training and practical experience. They prepare the student for obtaining a license to practice as a Registered Nurse.

Classroom work. Nursing students study such subjects as anatomy, chemistry, nutrition, pharmacology, physiology, psychology, and sociology, as well as the fundamentals of nursing care. They learn to care for the sick by working in the nursing laboratory. Frequently, the students practice on one another. For example, one

student may take another's temperature, blood pressure, and pulse rate.

Clinical experience. In all schools of nursing, classroom work or theory is interwoven with practice. Clinical experience, or practice, means the time that the student spends in learning to care for different types of patients. As part of their clinical experience, students also learn something about hospital routine and the functions of various departments, and get the "feel" of hospital life.

Nursing students have experience with all types of patients. A teacher who is an expert nurse supervises all their early activities. As students gain experience and knowledge, they work more independently.

Licensing. After graduation from an approved school of nursing, professional and technical nurses in the United States and in some Canadian provinces must pass a written examination. The nurse then receives a license to practice the profession in the state or province. She or he is now a registered nurse (R.N.).

Nurses may advance their careers by additional study and experience. A master's degree is often the step to specialization, teaching, or administration. To advance further, a nurse may earn a doctoral degree as preparation for teaching and conducting research.

Practical nursing courses usually last one year. Like professional and technical nursing education, practical nursing courses combine classroom study with actual experience.

There are two types of schools of practical nursing, public and private. Some public schools teach practical nursing as part of their vocational-training or adult-education programs. Private schools are operated by hospitals, health agencies, and by some junior colleges and universities.

Credits for courses taken at vocational nursing schools cannot be directly transferred to professional or technical nursing schools. However, some nursing school programs allow vocational nurses to obtain a degree without repeating basic courses.

In all the states, and in some Canadian provinces, a practical nurse, like a professional nurse, must obtain a license to practice. He or she then becomes a Licensed Practical Nurse (L.P.N.), sometimes called a Licensed Vocational Nurse (L.V.N.).

Career information. A high-school student who wants to learn about a nursing career should talk with a vocational guidance counselor, school nurse, or other nurses. Many high schools have Future Nurses clubs whose members visit hospitals and schools of nursing and do volunteer work. Serving as a nurse's aide or as an orderly in a hospital is another way to learn more about nursing (see Nurse's aide). Information on professional, technical, and practical nursing may be obtained from the National League for Nursing in New York City.

The history of nursing

Some form of nursing care has probably been practiced for thousands of years. For example, the early Israelites and Egyptians hired women, later called *midwives,* who assisted at births.

Nurses first organized in groups during early Christian times. Noblewomen, including the wives of the emperors, helped care for the ill in ancient Rome. During the Crusades, military nursing orders of monks and knights tended the sick and wounded.

Many monasteries closed during the Reformation, and there were only a few places where religious orders could nurse the sick. The years from 1600 to 1850 were the darkest period in the history of nursing. Hospitals often were built as charity hospitals and were usually staffed by untrained, sometimes disreputable, women. Wealthy people never went to hospitals. The importance of sanitation and hygiene was unknown. People did not understand how diseases spread. Nurses who took care of patients with contagious diseases often contracted these diseases themselves.

Nursing as we know it began in the 1850's with the work of the English nurse Florence Nightingale, the founder of modern professional nursing. Nightingale established the first school of nursing, the Nightingale Training School for Nurses, in London in 1860. Graduates of this school traveled to all parts of the world to teach nursing.

The first nursing schools in the United States were established in 1873 at Massachusetts General Hospital in Boston, Bellevue Hospital in New York City, and the New Haven (Connecticut) Hospital. The American Nurses' Association, Inc., an organization of registered nurses, was organized in 1896.

Many nurses have won world fame. They include Clara Barton, Edith Cavell, Elizabeth Kenny, and Lillian D. Wald. Pamela J. Maraldo

Nursing home is a residential institution that provides medical or nonmedical care, chiefly for people who are 65 years old or older. Nearly all homes also accept younger patients. In the United Kingdom, some private maternity hospitals are called nursing homes. The best nursing homes strive to provide a comfortable, homelike environment for their residents.

Most nursing homes are privately owned. Others are operated by federal, state, provincial, or local governments. Some private nursing homes are run by corporations, which try to earn a profit for the owners. Others are sponsored by religious or civic groups, which do not have a primary goal of making money.

Most countries have laws governing the operation of nursing homes and require the institutions to have a license. Inspectors visit the homes periodically to make sure they follow these laws.

Types of nursing homes

There are three types of nursing homes: (1) skilled nursing care homes, (2) intermediate care facilities, and (3) supervised assisted living facilities. They differ according to the types of patients they care for and the

inds of services they offer.

Skilled nursing care homes provide more extensive ervices than the other types of nursing homes. For example, they offer diagnostic, laboratory, and medication ervices; therapy programs; and dental care. Registered urses supervise the care of patients according to the nstructions of the institution's medical director. Physiians visit these homes frequently. Most skilled nursing are homes are run by licensed administrators.

Most of the patients in skilled nursing care homes reuire medical attention around the clock. Some have seious illnesses or disabilities. Others stay in these instituons after being hospitalized. They receive additional reatment before returning home.

Most skilled nursing care homes have transfer agreeents with hospitals, intermediate care facilities, and ther health-care institutions. Patients who become so ill at they need more medical care than a nursing home an provide are taken to a hospital. Those whose health nproves, but who still require some nursing care, are ransferred to an intermediate care facility or other ealth-care institution.

Intermediate care facilities, also called basic nursng care homes, provide basic nursing services. Regisered nurses examine the residents periodically to deterine what treatment is needed. Most patients in ntermediate care facilities suffer from a long-term illess, such as Alzheimer's disease or Parkinson's disease. lowever, they require only minor medical care. Doctors isit these nursing homes regularly.

Registered nurses direct the nursing programs in inrmediate care facilities, but an administrator runs nese institutions.

Supervised assisted living facilities provide nonedical services. These services include preparing and erving the residents' meals and helping the men and vomen care for themselves. For example, members of e staff assist residents who have difficulty dressing emselves. The institutions also plan outings and other ocial activities for the residents.

Most residents of assisted living facilities need only outine medical examinations, and physicians visit these omes only when necessary. A supervisor of residential are directs the services provided.

Selecting a nursing home

Quality of care. In selecting a nursing home, it is imortant to match both the medical and psychological eeds of a person with the resources of the caregiving nstitution.

For example, not all older adults require the same mount of medical care. A study of nursing homes reealed that a number of relatively healthy people lived in nstitutions that had extensive medical facilities. The tudy also found that many people who needed medical eatment lived in nursing homes that did not have adeuate medical services.

Nursing homes also should provide for the psychogical needs of their residents. Most people in nursing omes can still lead productive lives. However, some w-quality institutions have few or no activities for residents. The best nursing homes encourage residents to ay active and to participate in a variety of community ervice and social activities.

Emotional effects. Many families feel guilty about placing an elderly relative in a nursing home. In most cases, they agree to this action only as a last resort. They do so when the person's health problems grow too severe and the family's social and financial resources become too strained to keep the relative at home.

Many elderly people suffer stress when they must adjust to the unfamiliar environment of a nursing home. Some older people regard it as the final step before death. The strain of the move can result in depression, increased health problems, and, in certain cases, even death.

There are several ways to lessen the strain on older people, including involving them in the decision to move to a nursing home and in the choice of a facility. The institution should allow patients to keep personal belongings in their new room. It is also important to choose a home where the staff is well trained and concerned about the patients. Nancy P. Kropf

Nut, Egyptian goddess. See **Mythology** (Egyptian mythology).

Nut is the popular name for many kinds of dry, edible seeds or fruits that grow in a woody shell. The word *nut* can refer to both the shell and the nutmeat, or kernel, inside or to the kernel alone. Nut-bearing plants grow in almost every part of the world.

Botanists define a nut as a dry, one-seed fruit surrounded by a hard shell that does not open on its own. Many edible nuts, including filberts and walnuts, are true nuts. But people also eat other kinds of nuts, such as almonds, coconuts, and peanuts, that are not true nuts. In fact, peanuts are related to peas (see **Peanut**).

Uses of nuts. Most people eat nuts as snacks or use them as flavoring in cooking. Many peanuts are used in peanut butter, candies, and cookies. Most nuts are rich in protein and fat, though chestnuts and a few others have more starch than protein. In Italy, bread is sometimes baked with a flour made from chestnuts.

Prehistoric people probably ate nuts as a regular part of their diet. Some nutritionists believe that, because of food shortages, nuts will again become a widely used source of protein.

In addition to their value as food, some nuts provide useful oil. For example, peanut oil and walnut oil are used in cooking. Walnut oil is also used to clean and polish wooden furniture. Jojoba nuts furnish a valuable lubricant for precision instruments. Tung oil is used in paints and varnishes.

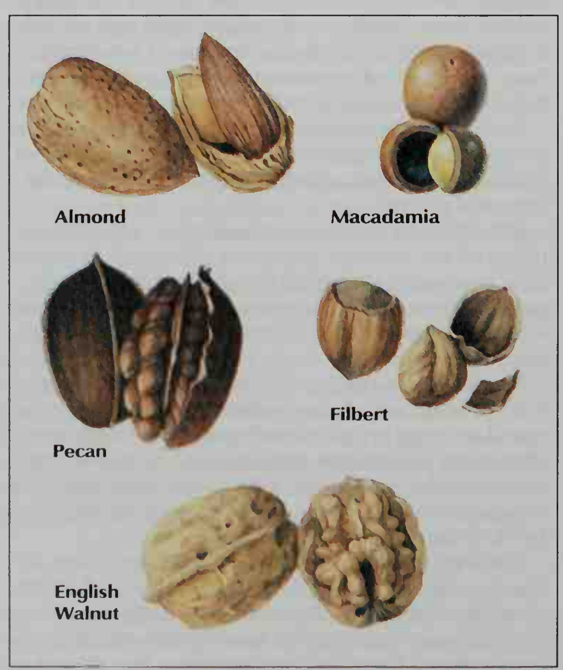
Kinds of nuts. Hundreds of species of shrubs and trees produce nuts, but only about 25 kinds of nuts are raised as crops. In the United States, nut growers produce more peanuts than any other type of nut. Almonds rank second in production, followed by English walnuts, also called Persian walnuts; pecans; black walnuts; filberts, or hazelnuts; and macadamia nuts.

The leading peanut-growing countries are China, India, Nigeria, and the United States. Growers in Georgia produce most of the U.S. peanut crop. California produces about one-third of the world's almonds, plus large crops of English walnuts and pistachios. Pecans, a type of hickory nut, are raised in many Southern and Western states. Pecans are also raised in Australia, Mexico, South Africa, and the Middle East.

Leading nut-growing states

Tons of nuts produced in a year*

State	Production
Georgia	749,000 tons (679,000 metric tons)
California	687,000 tons (623,000 metric tons)
Texas	445,000 tons (404,000 metric tons)
Alabama	198,000 tons (179,000 metric tons)
North Carolina	177,000 tons (160,000 metric tons)



*Includes almonds, hazelnuts, macadamia nuts, peanuts, pecans, pistachio nuts, and walnuts. Figures are for a three-year average, 1998-2000.
Source: U.S. Department of Agriculture.

Black walnuts grow in the Midwest and East. Unlike most kinds of commercial nuts, which are raised in orchards, black walnuts are collected from wild trees. Filberts grow on large shrubs or small trees and are a major crop in Oregon and in Italy, Spain, and Turkey.

Chestnuts are produced in China, Italy, Japan, Korea, and Turkey. A disease killed almost all American chestnut trees during the early 1900's.

Macadamia trees were first brought to Hawaii from Australia in the late 1800's. Today, Hawaii ranks as the world's chief producer of macadamia nuts. Brazil nuts grow in the Amazon River region of South America. Other tropical nuts include cashews and coconuts.

Nut growing. Most kinds of nut trees produce nuts only if they have been *cross-pollinated*—that is, pollinated by flowers from another tree of the same species.

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd.

Nuts grow nearly everywhere in the world. Some popular nuts produced in the United States are almonds, pecans, filberts or hazelnuts, and English walnuts.

Nut growers raise new trees by grafting certain parts o one tree to the roots of another (see **Grafting**).

Nut trees—and nuts themselves—may be damaged b a number of pests and diseases. For example, mice, squirrels, weevils, and some species of birds eat nuts and feed on nut crops. Nut trees can be harmed by cer tain insects and diseases that attack the leaves, stems, o nuts. Nut growers commonly protect their crops from insects and diseases by spraying the trees with pesticides. They use firearms, mechanical barriers, poisons, repellents, traps, and various other means to control birds and rodents. Richard A. Jaynes

Nutcracker is the name of two species of birds. *Clark nutcracker* lives in evergreen forests in the mountains c western North America. It is gray with black and white wing and tail feathers and is 12 inches (30 centimeters) in length. The *Eurasian nutcracker* is found in similar regions in Europe and Asia. It is reddish-brown with white markings, and it has black wings. Nutcrackers have a strong, direct flight.

Clark's nutcracker feeds chiefly on the seeds of pine cones. It holds the cones in its sharp, heavy, curved claws while opening them with its bill. The Eurasian nutcracker feeds on the seeds of pine cones and hazelnuts. Both species also eat insects, berries, and the eggs of other birds. They often store seeds and nuts for use during the winter.

WORLD BOOK illustration by John Rign Linden Artists Ltd.

Nutcracker

Clark's nutcracker hides its nest at the top of a tall pine. During winter, the female lays from three to five speckled, grayish-green eggs. Both Clark's nutcracker parents care for the eggs and the young. Sandra L. Vehrencamp

Scientific classification. Nutcrackers belong to the crow family, Corvidae. The scientific name for Clark's nutcracker is *Nucifraga columbiana*. The Eurasian nutcracker is *N. caryocatactes*.

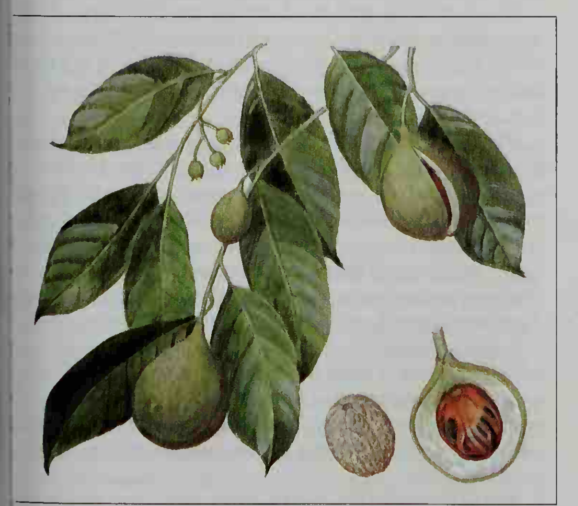
Nuthatch is the name of a group of tree-climbing songbirds. They are common throughout the temperat regions of the world. Nuthatches get their name from their habit of wedging nuts into cracks in tree bark and then *hatching* (opening) them with repeated strokes of the bill. Unlike other climbing birds, nuthatches often creep down tree trunks headfirst.

The best-known North American species is the *whit breasted nuthatch*. This bird lives year-round in the Uni ed States and southern Canada and can be found in

woodlands, orchards, and yards. It measures about 5 to 6 inches (13 to 15 centimeters) in length. The top of its head and upper neck are black, its back is dark gray, and its underparts are white.

White-breasted nuthatches eat nuts and grain, as well as insects and insect larvae that they find underneath the bark of trees. In winter, these birds are easily attracted to feeding stations, where they eat sunflower seeds and *suet* (animal fat). The white-breasted nuthatch builds its nest in holes in trees or stumps. The female lays from 5 to 10 white eggs that are speckled with reddish-brown or lavender markings.

Wayne Lankinen, DRK Photo



Red-breasted nuthatch

Other North American nuthatches are the *red-breasted nuthatch,* which lives in southern Canada and in the northern and western parts of the United States; the *brown-headed nuthatch,* found in the Southern States; and the *pygmy nuthatch,* found in western North America and in Mexico. These species are smaller than the white-breasted nuthatch.

Scientific classification. Nuthatches belong to the nuthatch family, Sittidae. The scientific name for the white-breasted nuthatch is *Sitta carolinensis.* Martha Hatch Balph

See also **Bird** (pictures: Birds of forests and woodlands; Birds' eggs).

Nutmeg is a tropical tree that is grown commercially for the spice it provides. The spice, also called *nutmeg,* comes from the inner part of the tree's brown seeds. The seeds develop in small fruits that look like golden-yellow pears when ripe. Nutmeg trees are native to the Molucca (Spice) Islands. They are now raised in Indonesia, the West Indies, Brazil, India, and Sri Lanka.

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd.

Nutmeg is a tropical tree that bears small fruits. The spices mace and nutmeg are obtained from the seeds of the fruits.

The nutmeg tree grows up to 70 feet (21 meters) tall and is an evergreen. It has gray-green leaves that are long and pointed with well-marked veins. The small, pale-yellow flowers droop in clusters and develop into fruit. As the fruit ripens, the fleshy part becomes rather hard. It finally splits open showing a bright-scarlet membrane that partly covers the kernel of the seed. The spice called *mace* comes from this membrane (see **Mace**). Nutmeg is made by grating or grinding the kernels. It has a sweet, spicy flavor.

Nutmeg trees do not bear fruit until they are about nine years old. Each tree produces from 1,500 to 2,000 seeds yearly. The fleshy part of the fruit is sometimes preserved and eaten like candy. A clear oil called *oil of nutmeg* is made from the kernels.

Scientific classification. Nutmeg trees belong to the nutmeg family, Myristicaceae. Their scientific name is *Myristica fragrans.* David S. Seigler

Nutmeg State. See **Connecticut** (Colonial life).

Nutria, *NOO tree uh,* or *coypu, KOY poo,* is a large rodent that lives near water. Nutrias are native to South America. They were introduced into many parts of Europe and North America to be raised for their fur. However, most attempts to raise nutrias commercially have not been profitable.

Bruce Coleman, Bruce Coleman Ltd.

Nutrias are large aquatic rodents that originated in South America. The animals are valued for their brown, beaverlike fur.

The nutria has brown fur with a whitish-tipped muzzle. It has small ears; webbed hind feet; and a long, scantily haired tail. The tail makes up nearly half the total body length, which measures up to 40 inches (100 centimeters). Wild nutrias may weigh up to 20 pounds (9 kilograms).

Nutrias live along the banks of lakes, marshes, ponds, and rivers. They are excellent swimmers. They feed chiefly on water plants. Female nutrias give birth to an average of four or five young at a time.

Nutrias are serious pests in some regions of the Southeastern United States. They dig holes in earthen dams and dikes and disrupt the balance of nature by destroying water plants. They also damage rice and sugar cane crops.

Nutrias are trapped in Louisiana. The fur is made into coats and gloves. The meat is used for pet food.

Scientific classification. The nutria belongs to the family Myocastoridae. Its scientific name is *Myocastor coypus.*

Hugh H. Genoways

© Lawrence Migdal

A balanced diet is the key to good nutrition. It supplies all the food substances the body needs. The family shown here enjoys a breakfast that includes fruit, cereal, bread, and milk. The daily diet should include several servings of these foods.

Nutrition

Nutrition is the science that deals with food and how the body uses it. People, like all living things, need food to live. Food supplies the energy for every action we perform, from reading to running. Food also provides substances that the body needs to build and repair its tissues and to regulate its organs and systems.

What we eat directly affects our health. A proper diet helps prevent certain illnesses and aids in recovery from others. An improper or inadequate diet increases the risk of various diseases. Eating a balanced diet is the best way to ensure that the body receives all the food substances it needs. Nutrition experts recommend that the daily diet include a certain number of servings from each of the five major food groups: (1) breads, cereals, rice, and pasta, (2) vegetables, (3) fruits, (4) milk, yogurt, and cheese, and (5) meat, poultry, fish, dried beans and peas, eggs, and nuts. Fats are also essential, but, like sweets, should be eaten in small quantities.

Workers in the field of nutrition oversee school food services, plan menus for hospitalized patients, and provide nutrition counseling for individuals. They administer international food programs and investigate the relationship between diet and health. They seek improved ways of processing, packaging, and distributing foods, and they create new foods.

How the body uses food

Food provides certain chemical substances needed for good health. These substances, called *nutrients,* perform one or more of three functions: (1) They provide materials for building, repairing, or maintaining body tissues; (2) They help regulate body processes; and (3) They serve as fuel to provide energy. The body needs energy to maintain all its functions.

The body breaks food down into its nutrients through the process of digestion. Digestion begins in the mouth. As food is being chewed, saliva moistens the particles. The saliva begins to break down such starchy foods as bread and cereals. After the food is swallowed, it passes through the *esophagus,* a tube that leads into the stomach. In the stomach, digestive juices speed up the break down of such foods as meat, eggs, and milk.

The partly digested food, called *chyme* (pronounced *kym),* passes from the stomach into the small intestine. In the small intestine, other juices break down the food into molecules that pass through the walls of the intestine and into the blood.

Blood distributes nutrients throughout the body. In the body's cells and tissues, the nutrients are broken down to produce energy, or are used to rebuild tissues or to regulate chemical processes. Some nutrients are stored in the body, and others are used over and over again. But most of the nutrients undergo chemical changes as they are used. These chemical changes produce waste products, which go into the bloodstream.

Some of these wastes are carried to the kidneys, which filter them from the blood. The body expels these wastes in the urine. The liver also filters out some wastes and concentrates them into a liquid called *bile.* In addition to concentrating certain wastes, bile helps digest fats.

Bile is stored in the gall bladder until it is needed to aid in digestion. Then the gall bladder empties bile into the small intestine. Bile then passes into the large intes-

Johanna T. Dwyer, the contributor of this article, is Professor of Medicine and Community Health at Tufts University Medical School and Director of the Frances Stern Nutrition Center, New England Medical Center Hospital.

ine, along with parts of the food not digested in the small intestine. The large intestine absorbs water and small amounts of minerals from this waste material. This material, along with bacteria present in the large intestine, becomes the final solid waste product, the *feces,* and it is eliminated from the body.

Kinds of nutrients

The foods we eat contain thousands of different chemicals. However, only a few dozen of these chemicals are absolutely essential to keep us healthy. These few dozen are the *nutrients*—the substances we must obtain from the foods we consume.

Nutritionists classify nutrients into six main groups: (1) water, (2) carbohydrates, (3) fats, (4) proteins, (5) minerals, and (6) vitamins. The first four groups are called *macronutrients,* from a Greek prefix meaning *large,* because the body needs them in large amounts. The last two groups, which are required in small quantities, are known as *micronutrients,* from a Greek prefix meaning *very small.*

Water is needed in great amounts because the body consists largely of water. Usually, between 50 and 75 percent of a person's body weight is made up of water.

The body requires large quantities of carbohydrates, fats, and proteins because these nutrients provide energy. Food energy is measured in units called *kilocalories.* A kilocalorie is equal to 1,000 *calories.* A calorie is the energy required to raise the temperature of one gram of water one Celsius degree. However, kilocalories are often referred to as simply "calories." The "calories" mentioned in this article are actually kilocalories.

Although minerals and vitamins are needed in only small amounts, they are as vital to health as any other nutrients. Minerals and vitamins are needed for growth and to maintain tissues and regulate body functions.

Water is, perhaps, the most critical nutrient. We can live without other nutrients for several weeks, but we can go without water for only about one week. The body needs water to carry out all of its life processes. Watery solutions help dissolve other nutrients and carry them to all the tissues. The chemical reactions that turn food into energy or tissue-building materials can take place only in a watery solution. The body also needs water to carry away waste products and to cool itself. Adults should consume about $2\frac{1}{2}$ quarts (2.4 liters) of water a day in the form of beverages or water in food.

Carbohydrates include all sugars and starches. They serve as the main source of energy for living things. Each gram (0.035 ounce) of carbohydrate provides about 4 calories.

There are two kinds of carbohydrates—*simple* and *complex.* Simple carbohydrates, all of which are sugars, have a simple molecular structure. Complex carbohydrates, which include starches, have a larger and more complicated molecular structure that consists of many simple carbohydrates linked together.

Most foods contain carbohydrates. The main sugar in food is *sucrose,* ordinary white or brown sugar. Another important sugar, *lactose,* is found in milk. *Fructose,* an extremely sweet sugar, comes from most fruits and many vegetables. Foods containing starches include beans, breads, cereals, corn, *pasta* (macaroni, spaghetti, and similar foods made of flour), peas, and potatoes.

Fats are a highly concentrated source of energy. Each gram of fat provides about 9 calories.

All fats are composed of an alcohol called *glycerol* and substances called *fatty acids.* A fatty acid consists of a long chain of carbon atoms, to which hydrogen atoms are attached. There are three types of fatty acids: *saturated, monounsaturated,* and *polyunsaturated.* A saturated fatty acid contains as many hydrogen atoms as its carbon chain can hold. A monounsaturated fatty acid is lacking one pair of hydrogen atoms. In a polyunsaturated fatty acid, the carbon chain contains at least four fewer hydrogen atoms than it could hold. A process called *hydrogenation* can attach additional hydrogen atoms to the carbon chains of unsaturated fatty acids. Hydrogenation may produce *trans fats,* in which newly added hydrogen atoms are connected in a slightly different position than the one in which they attach naturally.

Most saturated fatty acids occur in foods derived from animals, such as butter, lard, dairy products, and fatty red meats. But some come from vegetable sources, such as coconut oil or palm oil.

Polyunsaturated fatty acids are found in the oils of such plants as corn and soybeans and in such fish as salmon and mackerel. Certain polyunsaturated fatty acids called *essential fatty acids* must be included in the diet because the body cannot manufacture them. These essential fatty acids serve as building blocks for the membranes that surround every cell in the body. Common sources of monounsaturated fatty acids include olives and peanuts.

Proteins provide energy—4 calories per gram, as carbohydrates do—but more importantly, proteins serve as one of the main building materials of the body. Muscle, skin, cartilage, and hair, for example, are made up largely of proteins. In addition, every cell contains proteins called *enzymes,* which speed up chemical reactions. Cells could not function without these enzymes. Proteins also serve as *hormones* (chemical messengers) and as *antibodies* (disease-fighting chemicals).

Proteins are large, complex molecules made up of smaller units called *amino acids.* The body must have a sufficient supply of 20 amino acids. It can manufacture enough of 11 of them. Nine others, called *essential amino acids,* either cannot be made by the body or cannot be manufactured in sufficient amounts. They must come from the diet.

The best sources of proteins are cheese, eggs, fish, lean meat, and milk. Proteins in these foods are called *complete proteins* because they contain adequate amounts of all the essential amino acids. Cereal grains, *legumes* (peanuts and other plants of the pea family), nuts, and vegetables also supply proteins. These proteins are called *incomplete proteins* because they lack adequate amounts of one or more essential amino acids. However, a combination of two incomplete proteins can provide a complete amino acid mixture. For example, beans and rice are both incomplete proteins, but together they provide the correct balance of amino acids.

Minerals are needed for the growth and maintenance of body structures. They are also needed to maintain the composition of digestive juices and the fluids that are found in and around cells. People need only small amounts of minerals each day.

Unlike vitamins, carbohydrates, fats, and proteins,

minerals are *inorganic compounds*—that is, they are not created by living things. Plants obtain minerals from the water or soil, and animals get minerals by eating plants or plant-eating animals. Unlike other nutrients, minerals are not broken down by the body.

Required minerals include calcium, chlorine, magnesium, phosphorus, potassium, sodium, and sulfur. Calcium, magnesium, and phosphorus are essential for healthy bones and teeth. Calcium is also necessary for blood clotting. Milk and milk products are the richest sources of calcium. Cereals and meats provide phosphorus. Whole-grain cereals, nuts, legumes, and green leafy vegetables are good sources of magnesium.

Still other minerals are needed only in extremely tiny amounts. These minerals, called *trace elements,* include chromium, copper, fluorine, iodine, iron, manganese, molybdenum, selenium, and zinc. Iron is an important part of hemoglobin, the oxygen-carrying molecule in red blood cells. Copper helps the body make use of iron to build hemoglobin. Manganese and zinc are required for the normal action of various enzymes. Green leafy vegetables, whole-grain breads and cereals, seafood, and liver are good sources of trace elements.

Vitamins are essential for good health because they regulate chemical reactions in which the body converts food into energy and tissues. There are 13 vitamins: vitamin A; the vitamin B complex, which is a group of 8 vitamins; and vitamins C, D, E, and K. Scientists divide vitamins into two general groups, *fat-soluble vitamins* and *water-soluble vitamins.* The fat-soluble vitamins—vitamins A, D, E, and K—dissolve in fats. The vitamins of the B complex and vitamin C dissolve in water. Small amounts of these compounds are needed daily.

Vitamin A is necessary for healthy skin and development of strong bones. Sources of this vitamin include liver, green and yellow vegetables, and milk.

Vitamin B_1, also called *thiamine,* is necessary for changing starches and sugars into energy. It is found in meat and whole-grain cereals.

Vitamin B_2, also known as *riboflavin,* is essential for complicated chemical reactions that take place during the body's use of food. Milk, cheese, fish, liver, and green vegetables supply vitamin B_2.

Vitamin B_6, also called *pyridoxine,* and two other B vitamins known as *pantothenic acid* and *biotin* all play a role in chemical reactions essential for growth. Liver, yeast, and many other foods contain these vitamins.

Vitamin B_{12} and folic acid, also called *folate,* are both needed for forming red blood cells and for a healthy nervous system. Vitamin B_{12} is found in animal products, especially liver. Folic acid is present in green leafy vegetables. Doctors recommend that all women who are capable of becoming pregnant consume small amounts of folic acid each day to reduce the risk of *spina bifida,* a serious birth defect.

Niacin is also part of the B complex. Cells need niacin to release energy from carbohydrates. Liver, yeast, lean meat, fish, nuts, and legumes contain niacin.

Vitamin C, also called *ascorbic acid,* is needed for the maintenance of ligaments, tendons, and other supportive tissue. It is found in fruits and in potatoes.

Vitamin D is necessary for the body's use of calcium. It is present in fish-liver oil and vitamin D-fortified milk. Vitamin D also forms when skin is exposed to sunlight.

Vitamin E, also known as *tocopherol,* helps maintain cell membranes. Vegetable oils and whole-grain cereals are especially rich in this vitamin. It is also found in small amounts in most meats, fruits, and vegetables.

Vitamin K is necessary for proper clotting of blood. Green leafy vegetables contain vitamin K. It is also manufactured by bacteria in the intestine.

Nutrition guidelines

Eat a balanced diet. The key to good nutrition is a varied diet that includes every kind of nutrient. To aid in planning a balanced diet, nutritionists have devised systems that group foods according to nutrient content. The Food Guide Pyramid pictured in this article is one such system, developed by the United States Department of Agriculture (USDA). The pyramid shape calls attention to the recommended amounts to eat from each of the major food groups. The groups at the broad base of the pyramid—that is, grains, fruits, and vegetables—should form the largest part of a healthful diet. Fewer daily servings should be chosen from meat and dairy groups near the top. Fats, oils, and sweets, at the narrow tip of the pyramid, should be eaten sparingly.

In the United States, the Food and Nutrition Board of the National Academy of Sciences issues Recommended Dietary Allowances (RDA's). RDA's are estimated amounts of various nutrients needed daily to avoid deficiency and maintain good nutrition in healthy people. The board issues a standard called *adequate intake* (AI) in cases where the board's experts feel there is insufficient evidence to establish an RDA. RDA's and AI's for particular nutrients may vary, depending on a person's sex or age. This article includes a table of certain RDA's.

RDA's and AI's are part of a larger category of standards called *dietary reference intakes* (DRI's). DRI's also include guidelines called *tolerable upper intake levels* (UL's). UL's define the maximum daily intake that is unlikely to harm health. DRI's are being developed in a joint effort by the U.S. Food and Nutrition Board and Health Canada. The World Health Organization is creating a set of similar standards.

The Nutrition Labeling and Education Act of 1990 requires that all packaged and processed food sold in the United States carry labels with nutritional information. These labels help people compare the nutritional content of the foods they eat with their daily dietary needs. Nutrition labels list the amounts of fats, carbohydrates, cholesterol, and certain other nutrients in one serving of the labeled food. The nutrients listed are those considered most important to health, as determined by the U.S. Food and Drug Administration (FDA). The label also provides a *Daily Value* percentage for each nutrient to show how it fits into a healthful diet. The percentages are based on guidelines called *Daily Reference Values* (DRV's); which the FDA established as the amounts of these nutrients that a healthy person should consume each day.

In addition, health claims, such as "reduces risk of heart disease," and descriptive terms, such as "fresh" and "low fat," can appear on food packages only in accordance with FDA regulations. A list of some of these descriptive terms and an illustration of a standard nutrition label accompany this article.

People vary in their needs for energy. A person who

The Food Guide Pyramid

The U.S. Department of Agriculture developed the Food Guide Pyramid to show recommended proportions of the major nutrient groups in a healthful diet for people 6 to 70 years old. People should eat more servings from groups at the bottom of the pyramid—grains, fruits, and vegetables—than from the meat and dairy groups near the top. Fats, oils, and sweets should be eaten in the smallest amounts.

Fats, oils, and sweets group: provides essential fatty acids and energy
Use sparingly

Meats, poultry, fish, dry beans, eggs, and nuts group: provides protein, iron, and vitamin B_{12}
- 2 to 3 servings daily
- One serving equals:
  - 1 egg
  - 2 to 3 ounces (57 to 85 grams) cooked chicken or other lean meat
  - 2 tablespoons (30 milliliters) peanut butter
  - $\frac{1}{2}$ cup (118 milliters) cooked dried beans

Milk, yogurt, and cheese group: provides vitamin A, vitamin B_2, calcium, and protein
- 2 to 3 servings daily
- One serving equals:
  - 1 cup (236 milliliters) skim or low-fat milk
  - 1 cup (236 milliliters) low-fat yogurt
  - 1 $\frac{1}{2}$ ounces (43 grams) natural cheddar or other hard cheese

Fruit group: provides vitamin C and fiber
- 2 to 4 servings daily
- One serving equals:
  - 1 apple, banana, or similar whole fruit
  - $\frac{1}{2}$ cup (118 milliliters) canned fruit
  - $\frac{3}{4}$ cup (177 milliliters) fruit juice
  - $\frac{1}{4}$ cup (59 milliliters) raisins or other dried fruit

Vegetable group: provides vitamin A, the B vitamins, vitamin C, calcium, iron, and fiber
- 3 to 5 servings daily
- One serving equals:
  - 1 cup (236 milliliters) salad greens
  - $\frac{1}{2}$ cup (118 milliliters) cooked vegetable
  - $\frac{1}{2}$ cup (118 milliliters) raw, nonleafy vegetable
  - $\frac{3}{4}$ cup (177 milliliters) vegetable juice

Source: U.S. Department of Agriculture

Bread, cereal, rice, and pasta group: provides complex carbohydrates, an important source of energy
- 6 to 11 servings daily
- One serving equals:
  - 1 slice bread
  - 1 ounce (28 grams) breakfast cereal
  - $\frac{1}{2}$ cup (118 milliliters) cooked rice or pasta
  - 2 pancakes

plays sports daily, for example, needs more calories than someone who does little physical work. Children need more calories than their size would indicate because they are growing. Pregnant women need extra calories to provide enough nutrients for a healthy baby.

Include fiber. Dietary fiber consists of complex carbohydrates that cannot be absorbed by the body. Fiber passes out of the body as waste. Fiber moves food along through the stomach and intestines, thus helping to prevent *constipation* (difficulty in emptying the bowels). Many experts believe that fiber also helps reduce the risk of such rectal and intestinal disorders as hemorrhoids, diverticulitis, and, possibly, cancers of the colon and rectum. Good sources of fiber include whole-grain breads and cereals, beans, peas, vegetables, and fruit.

Limit intake of saturated fats, trans fats, and cholesterol. Health experts recommend a diet that is low in saturated fats, trans fats, and *cholesterol,* a waxy substance found in many animal foods. Consumption of these substances raises the level of cholesterol in a person's blood, which increases the risk of heart disease. Animal products are the source of all dietary cholesterol and most saturated fats except coconut oil and other tropical oils. To reduce intake of saturated fats and cholesterol, experts suggest choosing lean meats, fish, poultry with the skin removed, and low-fat dairy products. They also advise using fats and oils sparingly. Trans fats occur chiefly in solid margarines and certain processed foods. Nutrition labels do not list trans fats. But the words *partially hydrogenated* in a product's ingredients often indicate that trans fats are present.

Limit intake of sodium and sugar. A diet that includes a great deal of sodium may increase the risk of high blood pressure. Sodium is found in many foods, including canned vegetables, frozen dinners, pickles, processed cheese, table salt, and such snack foods as pretzels, chips, and nuts. One way to reduce sodium intake is to use herbs and other seasonings instead of salt in cooking and at the table. Another way is to select fresh foods rather than canned or frozen items.

Foods that contain much sugar are often high in calories and fat but low in minerals, proteins, and vitamins. Nutritionists sometimes call these foods "empty calorie" foods, because they may make a person feel full but provide few nutrients. In addition, sugar that remains in and around the teeth contributes to tooth decay. Foods that have a large amount of sugar include candies, pastries, many breakfast cereals, and sweetened canned fruits. In place of sugary foods, nutritionists advise people to snack on fresh fruits and vegetables. They also recommend that people drink unsweetened juices instead of soft drinks.

Beware of alcohol. Alcoholic beverages supply calories, but they provide almost no nutrients. In addition, alcohol is a powerful drug, and habitual drinking can lead to serious health problems. Health experts recommend that people who choose to drink alcoholic beverages consume only small amounts. They further recommend that certain people avoid alcohol altogether, including children and adolescents; pregnant women; people who are about to drive; anyone who is taking medicine; and individuals who are unable to limit their drinking.

© R. Benzi, Custom Medic

Obesity may result from poor nutrition. Medical personnel should be consulted to develop and monitor a weight-loss program involving both diet and physical exercise.

Recommended daily dietary allowances of some chief nutrients

				Vitamins								
	Age	Calcium (mg)*	Iron (mg)	A (µg RE)	B_6 (mg)	B_{12} (µg)	C (mg)	D (µg)*	E (mg TE)	Niacin (mg NE)	Riboflavin (mg)	Thiamine (mg)

Food labels All packaged and processed foods sold in the United States must carry a label with the title *Nutrition Facts.* An example of a standard food label is illustrated below. Foods in small packages or foods that contain limited nutrients may carry a simplified version of this label. Fresh fruits and vegetables, single-ingredient raw meats, and a few other foods are not required to carry labels.

Food and Drug Administration (*World Book* chart)

Serving size reflects the amount people customarily eat as one portion. It must be stated in both household and metric measures.

The list of nutrients consists of those nutrients considered to be of special importance to the health of people in the United States, as determined by the Food and Drug Administration. In general, Americans need to avoid getting too much of certain nutrients, particularly fat, rather than too few vitamins and minerals. The nutrients shown here must be listed on all full-sized labels. They are measured in grams (g) and milligrams (mg), rounded to the nearest whole number.

Daily Value is the total amount of the nutrient that a person should eat in one day as part of a healthy diet. Daily Values are provided for diets of 2,000 and 2,500 calories a day. The values for fats, cholesterol, and sodium are the maximum amounts a person should eat each day. The values for carbohydrates are the minimum amounts.

Nutrition Facts
Serving Size 1 cup (228g)
Servings Per Container 2

Amount Per Serving

Calories 260 Calories from Fat 120

	% Daily Value *
Total Fat 13g	**20%**
Saturated Fat 5g	**25%**
Cholesterol 30mg	**10%**
Sodium 660mg	**28%**
Total Carbohydrate 31g	**10%**
Dietary Fiber 0g	**0%**
Sugars 5g	
Protein 5g	

Vitamin A	4%	Vitamin C	2%
Calcium	15%	Iron	4%

*Percent Daily Values are based on a 2,000 calorie diet. Your daily values may be higher or lower depending on your calorie needs:

	Calories:	2,000	2,500
Total Fat	Less than	65g	80g
Sat Fat	Less than	20g	25g
Cholesterol	Less than	300mg	300mg
Sodium	Less than	2,400mg	2,400mg
Total Carbohydrate		300g	375g
Dietary Fiber		25g	30g

Calories per gram:
Fat 9 • Carbohydrate 4 • Protein 4

Calories from fat are shown to help people limit the amount of fat they consume. Nutrition experts recommend that adults get no more than 30 percent of their daily calories from fat. Such a low-fat diet can help reduce the risk of heart disease and some forms of cancer. The number of calories is rounded to the nearest five or ten.

% Daily Value is the percentage of the Daily Value of the nutrient that a person gets by eating one serving of the labeled food. This percentage is based on a healthy diet of 2,000 calories a day. People who eat more or less than 2,000 calories a day can adjust these figures to fit their own calorie intake.

Calories per gram shows that 1 gram of fat provides approximately 9 calories, and 1 gram of either carbohydrates or protein provides approximately 4 calories. These values apply to all foods, so this section is the same on all labels.

ome terms used in labeling food

Certain descriptive terms can appear on food packages only if the food meets requirements set by the Food and Drug Administration. A list of some of these terms follows.

ree means the food contains nutritionally insignificant nounts of the specified nutrient. For example, a can of chicken oup labeled "sodium-free" must contain no sodium or an insig-ficant amount of sodium.
resh, as in "fresh orange juice," means the food is raw, con-ins no preservatives, and has not been processed, heated, or ozen.
ealthy means the food is low in fat and saturated fat and con-ins no more than 480 milligrams of sodium and 60 milligrams cholesterol per serving.
igh, as in "high in fiber" or "high in protein," means the food ovides 20 percent or more of the Daily Value of the specified itrient per serving.
ean applies to meats, poultry, and seafoods that contain fewer an 10 grams of fat, 4 grams of saturated fat, and 95 milligrams cholesterol per serving.
ss means the food contains at least 25 percent less of the ecified nutrient than does a similar, specified food. For example, a package of pretzels could be labeled "less fat than potato chips," provided that the pretzels have at least 25 percent less fat.
Light or **lite,** as in "lite sour cream," means the food has been altered during processing to contain one-third fewer calories or one-half less fat or sodium than the regular product.
Low, as in "low fat" or "low sodium," means the food can be eaten frequently without exceeding Daily Value guidelines for the specified nutrient.
More means the food contains at least 10 percent more of the Daily Value for the specified nutrient than does a similar, specified food. For example, grapefruit juice could be labeled "more vitamin C than orange juice," provided the grapefruit juice has at least 10 percent more vitamin C.
Source of or **Good source of,** as in "source of calcium" or "good source of fiber," means a serving has 10 to 19 percent of the Daily Value of a particular nutrient.

Do not overeat. When people consume more calories than they need, their bodies store most of the extra calories as fat. Accumulation of fat can result in *obesity,* a condition in which a person has too much body fat for good health. Obesity increases the risk of such diseases as adult-type diabetes, stroke, high blood pressure, gall bladder disease, heart disease, and certain cancers. Conditions such as osteoarthritis and low back pain may be worsened by the pressure of excess weight.

A number of techniques may help people avoid obesity. Most health experts recommend that people exercise regularly to help control their weight. Another strategy is to avoid using food as a reward or as a way to overcome loneliness or boredom. Experts also advise against snacking on foods that are high in fat or sugar. Instead, they recommend such choices as fruits or vegetables, unsalted crackers, nonfat yogurt, and unsweetened fruit juice, skim milk, or sparkling water.

Store and cook foods properly to retain their nutritional value. For example, many fresh foods should be kept in the refrigerator. They should be washed thoroughly and eaten as soon as possible. Frozen foods must be kept frozen in a freezer.

Vegetables should be cooked quickly in as little water as possible to minimize vitamin loss in the water. Avoid frying meats and other animal foods. Instead, cook them by broiling, stir-frying, braising, or poaching. These methods result in food that is tasty but free of added fat and extra calories. Microwave cooking reheats food quickly and keeps nutrient values high.

Evaluate claims about foods and dietary supplement carefully. People should use caution, common sense, and critical thinking to evaluate popular ideas or advertising claims about foods and dietary supplements. Some ideas about foods and supplements become popular even though they are wrong. For example, some people believe that they need not eat a balanced diet if they take a vitamin pill every day. But, in fact, people who rely on vitamin pills may not get all the calories, minerals, or proteins that they need.

Although labeling and advertising claims are regulated by federal agencies, people may develop mistaken ideas from claims that meet legal requirements. For example, some people think they can eat unlimited quantities of foods labeled "low fat." In fact, careful comparison of labels shows that many low-fat foods contain almost as many calories as do versions not labeled low-fat.

People should carefully consider the source of nutritional claims. Reliable sources of information include state, provincial, and national health and nutrition agencies; public departments of agriculture; and universities with expert knowledge in health and nutrition.

Nutrition and disease

An improper or inadequate diet can lead to a number of diseases. On the other hand, good nutritional habits can help prevent certain diseases.

Heart disease in its most common form is called *coronary artery disease* (CAD). CAD narrows coronary arteries and so reduces the blood supply to the heart. It can lead to crippling attacks of chest pain and, eventually, to life-threatening heart attacks. High blood pressure and high levels of blood cholesterol are two of the major risk factors for CAD. In many cases, people can lower these risk factors with good nutritional practices.

Many people can reduce mild high blood pressure by limiting their intake of salt and calories. Similarly, many people can lower their blood cholesterol level by reducing the amount of fat—particularly saturated fat—cholesterol, and calories in their diet. They can achieve these reductions by avoiding such foods as butter, cakes, cookies, egg yolks, fatty meats, tropical oils, and whole-fat dairy products.

Cancer. Scientists have found that heredity, environment, and lifestyle all play a role in causing cancer. They have also learned that good nutrition can help prevent certain kinds of cancer in laboratory animals. Large doses of vitamins A and C have been shown to prevent some cancers in animals. Many scientists believe that certain foods contain substances that may help prevent some cancers in people. Such foods include broccoli, cabbage, carrots, cauliflower, fruits, spinach, whole-grain breads and cereals, cooked tomatoes, and some seafoods. Lessening intake of fats and increasing the intake of fiber may also help prevent some cancers.

Deficiency diseases result from an insufficient amount of certain nutrients in the diet. Such diseases can usually can be eliminated when adequate amounts of the nutrient are provided. Deficiency diseases are most widespread in less developed countries, where people may lack adequate food. These diseases are less common in most developed countries, where a variety of foods are available all year, and many foods are fortified with vitamins and minerals.

Protein-calorie malnutrition, also called *protein-energy malnutrition,* occurs when the diet is low in both proteins and calories. If the diet is especially low in proteins, the condition is called *kwashiorkor.* Signs of kwashiorkor include changes in the color and texture of the hair and skin; swelling of the body; and damage to the intestines, liver, and pancreas. The disease, which is common in some less developed nations, usually attack children who are suffering from an infectious disease. Kwashiorkor is fatal unless the patient is given protein along with food providing calories. If the diet is especially low in calories, the condition is called *marasmus.* Marasmus usually attacks infants and young children, and it causes extreme underweight and weakness.

Vitamin deficiencies. The signs and symptoms of

Fred Griffing, UNIC

A diet especially low in proteins may cause *kwashiorkor,* a disease that generally strikes children. In severe cases, the muscles waste away and the skin swells with body fluids.

vitamin deficiencies vary according to the missing vitamin. Vitamin C deficiency, also called *scurvy,* causes sore and bleeding gums, slow repair of wounds, and painful joints. Vitamin D deficiency, also called *rickets,* causes abnormal development of bones. A deficiency of niacin and the amino acid tryptophan, found in protein, causes *pellagra.* The early symptoms of pellagra include weakness, lack of appetite, diarrhea, and indigestion.

Mineral deficiencies. The most common mineral deficiency disease is *iron-deficiency anemia.* In this disease, lack of iron prevents formation of enough oxygen-carrying red blood cells. As a result, the blood cannot supply the tissues with sufficient oxygen. Thus, the person feels weak or tired. Other symptoms include dizziness, headaches, rapid heartbeat, and shortness of breath. A lack of iodine can cause *goiter,* a disease in which the thyroid gland becomes enlarged.

Other diseases may result from poor nutritional habits. For example, excessive intake of alcohol causes some forms of liver disease. The risk of *osteoporosis* (loss of bone tissue) is higher for people—especially women— whose intake of calcium and level of physical activity are low. To prevent osteoporosis, physicians recommend a lifelong combination of regular exercise and a diet with adequate calcium.

Careers in nutrition

Nutrition offers a variety of careers in work settings that range from restaurants to research laboratories. Jobs in this field require at least a high school education. Some positions require a two-year associate's degree or a bachelor's degree. High school students interested in a career in the field of nutrition should take such science courses as biology and chemistry. College students preparing for a career in nutrition study physiology—the science that deals with how the body works—as well as biochemistry—the science of the chemical reactions that take place in living things. Other required courses include bacteriology and general chemistry. Students interested in careers in medical nutrition learn how diseases affect the body. Students pursuing careers in food service take such courses as food preparation, food purchasing, accounting, and personnel management.

Work as a *dietetic technician* requires an associate's degree. Dietetic technicians work as members of a food service staff or a health care team, under the supervision of a *registered dietitian.* These technicians supervise support staff, develop nutrition care plans, and provide nutrition counseling for individuals or small groups.

A bachelor's degree and a period of supervised practice are necessary to become a registered dietitian. Candidates must also pass a registration examination. Many registered dietitians manage food services in schools, nursing homes, and restaurants. Others work in hospitals or clinics, planning special diets for people who are ill. Some registered dietitians coordinate disease prevention programs for public health organizations or work with community food programs. Others work for corporations, helping to develop food products. A number of registered dietitians offer personal nutrition counseling directly to the public.

People with advanced degrees in nutrition and food science may teach; conduct research projects for government, business, industry, and health care institutions; or hold administrative positions in international food or agricultural programs. These experts may investigate the effect of diet on health or develop improved methods for processing and packaging food. Some create new foods, such as artificial sweeteners, fat substitutes, or foods used in space exploration. Johanna T. Dwyer

Nutting, Mary Adelaide (1858-1948), was a leader in the development of professional nursing in the United States. She helped establish professional standards in nursing education and the practice of nursing. She developed a model training program that supplemented practical experience in a hospital with practical instruction in nursing principles.

Nutting was born in Quebec, Canada. In 1889, she went to Baltimore to enter the first class of the Johns Hopkins Hospital Training School for Nurses. After graduating in 1891, she served as a head nurse at the school. In 1894, she became the school's principal. Nutting held this position until 1907. That year, she joined the faculty of Teachers College at Columbia University in New York City and became the world's first professor of nursing. Nutting headed the Department of Nursing and Health at the college from 1910 until she retired in 1925.

Nye, Bill (1850-1896), was a popular American humorist. He became famous for his clever essays and *anecdotes* (brief stories) on a variety of subjects ranging from the American West to journalism. Nye was also a successful comic lecturer.

Nye was born in Shirley, Maine. His full name was Edgar Wilson Nye. In 1876, Nye moved to Wyoming. He first gained national fame as a columnist for the Laramie *Boomerang,* a newspaper he founded in 1881. In 1886, Nye moved to New York City and wrote humorous columns for the New York *World* newspaper. His books include *Bill Nye's History of the United States* (1894) and *Bill Nye's History of England* (1896). Both were widely popular for their satirical treatment of the past. Nye and the American poet James Whitcomb Riley wrote *Nye and Riley's Railway Guide* (1888), a book of poems and witty prose sketches. David B. Kesterson

Nyerere, *nih RAIR ee,* **Julius Kambarage,** *kahm BAH rah guh* (1922-1999), was president of Tanzania from 1964 until he retired in 1985. Tanzania consists of Tanganyika, a region on the African mainland; and Zanzibar, a nearby island group. Tanganyika and Zanzibar were formerly ruled by the United Kingdom. Nyerere led the movement that resulted in Tanganyika's independence from the United Kingdom in 1961. He became the president of Tanganyika in 1962. He also helped unite Tanganyika and Zanzibar to form Tanzania in 1964, and he became the new country's president. He was first elected president in 1965 and was reelected in 1970, 1975, and 1980. Nyerere retired as president in 1985 and as chairman of the only legal political party in 1990. But he remained a major influence in Tanzania until his death.

As Tanzania's president, Nyerere became a leading spokesman for cooperation among black African nations, and he helped unite Tanzania's many ethnic groups. In 1979, Nyerere sent Tanzanian troops to Uganda, after Uganda had invaded Tanzania. The Tanzanian troops helped overthrow the dictatorship of Idi Amin Dada in Uganda.

Nyerere was born near what is now Musoma, Tanzania. He was educated at various schools in what are now Tanzania and Uganda and at the University of Edinburgh in Scotland. Robert I. Rotberg

Nylon is the general term for a group of synthetic products. These products are made from chemicals derived from coal, water, air, petroleum, agricultural by-products, and natural gas. Nylon is one of the most important chemical discoveries. It is a tough elastic substance that can be formed into fibers, bristles, sheets, rods, and tubes. It also can be made in powdered form for use in molding operations.

Nylon fibers and fabrics are noted for their strength, ability to be dyed, low shrinkage, silklike appearance, and resistance to abrasion, mildew, and insects. They are not harmed by most kinds of oil and grease or by household cleaning fluids. Nylon fabrics dry rapidly because nylon absorbs little water.

Uses. Nylon is used primarily in fibers and fabrics. It was the first synthetic fabric thought to be superior to natural fabrics. Nylon hosiery came on the market in 1939. Since then, many uses have been found for nylon. Carpets, tires, upholstery, dresses, underwear, bathing suits, lace, and parachutes are among the many nylon products. Single threads of nylon are used for fishing line and for bristles in brushes. Surgeons use nylon thread to sew up wounds.

Nylon is also important in the plastics industry. Nylon plastics are noted for their electrical properties, toughness, and resistance to chemicals, fire, and wear. They are used in such products as electrical equipment, gears, tubing, and sporting equipment. Plastic nylon body panels have replaced steel on some automobiles.

How nylon is made. Most nylon produced in the United States is made from two chemical compounds—*hexamethylenediamine* and *adipic acid.* Both of these compounds contain carbon and hydrogen. Manufacturers combine the compounds to form *hexamethylene-diammonium-adipate,* commonly called *nylon salt.*

Most nylon factories make the substance by placing a solution of nylon salt in a machine called an *autoclave.*

The autoclave heats the solution under pressure. The water is removed, and the molecules that make up each of the compounds combine to form large molecules. This process of making large molecules from smaller ones is called *polymerization.* In some factories, the newly formed nylon comes out of the machine as a plastic ribbon. The ribbon is cooled, hardened, and cut into chips that are used in making a variety of nylon products. See **Plastics** (How plastics are made).

Nylon fibers are made by forcing molten nylon through tiny holes in a device called a *spinneret.* In some factories, the molten nylon travels to the spinneret as soon as the polymerization process is completed. Other factories melt nylon chips and pump the melted nylon through the spinneret. The streams of nylon harden into filaments when they strike the air. Then they are wound onto bobbins. From 1 to as many as 2,520 filaments are united into a textile nylon yarn.

Nylon fibers are *drawn* (stretched) after they cool. Some factories draw nylon after it has been spun into yarn. Others spin and draw the yarn in one operation. Drawing involves unwinding the yarn or filaments from one spool and winding them onto another. The winding rate is four or more times as fast as the unwinding rate. The pull between the spools stretches the fibers. Drawing makes the molecules in each filament fall into parallel lines. This process gives the fiber strength and elasticity. After being drawn, the yarn may be twisted a few turns per yard or per meter as it is wound onto spools. It may also be treated to give it a special texture or bulk.

The size of nylon yarn is measured in *deniers.* A denier is the weight in grams of 9,000 meters (9,843 yards) of the yarn. For example, if 9,000 meters of a nylon yarn weigh 15 grams, the yarn is called *15-denier* yarn.

History. Wallace H. Carothers, a chemist of the DuPont Company, was a leader in the development of nylon. In the late 1920's, he began to experiment with polymerization. He used a machine called the "molecular still," which made it possible to make longer molecules than had been made before. Carothers found that many of the fibers made from compounds that he polymerized could be pulled out to several times their original length after they were cooled. This pulling process made the fibers much stronger and more elastic.

But most compounds that Carothers had made so far melted at a temperature too low to make them practical for textiles that must be ironed. Then, in 1935, he polymerized hexamethylenediamine and adipic acid. The product was called *polyhexamethylene adipamide.* This material had a melting point of 482 °F (250 °C), which is satisfactory for textiles. The new fiber was named nylon and was hailed as a great discovery. Later, chemists referred to this original kind of nylon as *nylon 66* because both chemicals used in making it had six carbon atoms.

Before nylon could be produced for the public, scientists had to find a way to make large amounts of hexamethylenediamine and adipic acid. Researchers at DuPont eventually developed a method for making these chemicals from petroleum, natural gas, and agricultural by-products. Nylon production began in 1938, and the first products made from nylon were introduced in 1939.

Most manufacturers in the United States have continued to produce nylon 66. However, other types of nylon have also been developed. Nylon 6, made from a six-carbon chemical called *caprolactam,* is a major fiber produced in the United States and numerous other countries. A silklike nylon with the trademark *Qiana* is a popular fiber that is used for clothing. Marvis E. Hartman

Nymph, in entomology. See **Larva**.

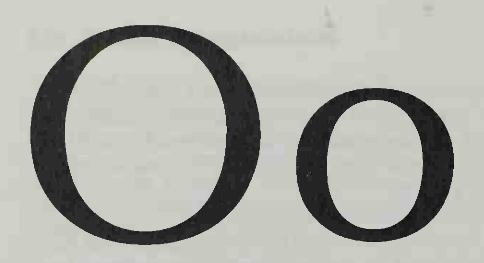
Nymph, *nihmf,* was a lovely maiden of Greek and Roman mythology who guarded the different realms of nature. *Oreads* watched over the hills and mountains, and *Nereids* kept watch over the Mediterranean Sea. The *naiads* were the nymphs of the rivers, brooks, and streams. The ocean was protected by the *Oceanids.* The *dryads* and *hamadryads* took care of the trees and forests.

Many of the naiads watched over springs that were believed to inspire those who drank their waters. The naiads were thought to have powers to prophesy and to inspire people. The oreads were also known by names that came from the hills or mountains where they lived.

Nymphs were sometimes shy. But at other times, they were passionate lovers. They were generally friendly and kind to mortals but occasionally punished people who offended them. Nymphs are represented with fauns and satyrs in the forest, or playing around the keels of ships. Nymphs lived for a long time, but they were not usually considered immortal. Justin M. Glenn

See also **Arethusa**.

Nystagmus, *nihs TAG muhs,* is an involuntary, rhythmical movement of the eyes. The eyes may move from side to side, up and down, in a circle, or in a combination of these movements. The motions may be rapid or slow, and jerky or smooth. Nystagmus occurs normally, as when a person watches scenery from a moving train. This condition may also be produced by diseases of the eye, the ear, or the brain. Some people are born with nystagmus.



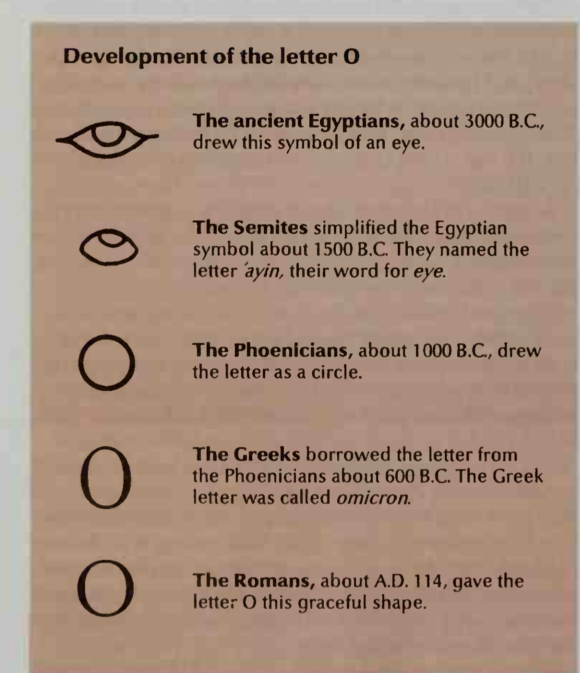
A type of nystagmus known as *miner's nystagmus* is caused by darkness and occurs among miners. *Positional nystagmus* occurs only when the patient's head is placed in an abnormal position or level. *Spontaneous ocular nystagmus* occurs as a result of complete blindness or from defective central vision. *Vertical nystagmus* is an up-and-down movement of the eyes. *Latent nystagmus* occurs when one eye is covered. Ronald Klein

Nzinga Nkuwu, *ehn ZIHNG ah ehn KOO woo* (?-1506), was the ruler of the Kongo kingdom in west-central Africa. His subjects believed he was God in human form.

After the first Portuguese trading ships came to Kongo in 1485, Nzinga Nkuwu welcomed trade with Portugal and established a friendly relationship with the Europeans. Portugal sent carpenters, farmers, traders, and other specialists to Kongo. But eventually the Europeans became more interested in developing the slave trade than in aiding the Kongolese.

After Christian missionaries came to Mbanza, Kongo's capital, Nzinga Nkuwu accepted Christianity as one of Kongo's religions. He was baptized in 1491 and took the name John I, or *João,* the name of Portugal's king. However, he gave up Christianity around 1495 because of disputes in his court between supporters and opponents of Christianity. Nzinga Mbemba, Nzinga Nkuwu's son, gained power shortly after Nzinga Nkuwu's death in 1506. A Christian supported by the Portuguese, Nzinga Mbemba took the name Afonso I. Kevin C. MacDonald

See also **Kongo**.



O is the 15th letter in our alphabet. It also appeared in the alphabet used by the Semites, who once lived in Syria and Palestine. They called the letter *'ayin,* their word for *eye.* For a symbol, they used a stylized picture of an eye. They probably borrowed it from an Egyptian *hieroglyphic* (picture symbol). The Phoenicians borrowed the letter from the Semites. Later, the Greeks borrowed it from the Phoenicians. They called it *omicron.* See **Alphabet.**

Uses. *O* or *o* is about the fourth most frequently used letter in books, newspapers, and other printed material in English. In chemistry, *O* stands for the element *oxygen.* On maps, the letter is the abbreviation for *ocean,* as well as *Ohio.* In modern numbering, it represents the *cipher,* or zero. In medieval Roman numerals, *O* represented the number 11 and $\overline{O}$, 11,000. It may also be used as the abbreviation for *old, octavo* (a size of book or method of folding a printed sheet), or *ohm* (a unit used in measuring electrical resistance).

Pronunciation. The letter *o* is a vowel, and has several sounds in English. The main pronunciations are illustrated in the words *November* (long *o*), *not* (short *o*), *off* (open *o*), and *out,* which scholars consider a *diphthong* (combination of short *o* and *u* sounds). Double *o* also has several sounds in English. When pronounced as a single vowel, it may have the sounds represented in the words *blood, food,* and *good.* There are some words in English in which each *o* is pronounced separately, as in *cooperate.* See **Pronunciation.**

Marianne Cooley

The small letter o first appeared during the A.D. 300's. Its shape changed little through the years.

A.D. 300 | 1500 | Today

Special ways of expressing the letter O

International Morse Code | Braille

International Flag Code | Semaphore Code | Sign Language Alphabet

Common forms of the letter O

Handwritten letters vary from person to person. *Manuscript* (printed) letters, *left,* have simple curves and straight lines. Cursive letters, *right,* have flowing lines.

Oo *Oo*

Roman letters have small finishing strokes called *serifs* that extend from the main strokes. The type face shown above is Baskerville. The italic form appears at the right.

Oo *Oo*

Sans-serif letters are also called *gothic letters.* They have no serifs. The type face shown above is called Futura. The italic form of Futura appears at the right.

Computer letters have special shapes. Computers can "read" these letters either optically or by means of the magnetic ink with which the letters may be printed.

O Canada is the national anthem of Canada. The Canadian Parliament adopted the song as the national anthem on June 27, 1980. Calixa Lavallée, a Canadian musician, composed the music in 1880. The song has both French and English lyrics. Sir Adolphe Basile Routhier, a Canadian judge, wrote the French lyrics in 1880. Another Canadian judge, Robert Stanley Weir, wrote the English words in 1908. In 1968, some of the wording in the English version was changed. The English lyrics are not a translation of the French lyrics.

The first stanza of the English lyrics is given below, followed by the first stanza of the French lyrics.

O Canada! Our home and native land!
True patriot love in all thy sons command.
With glowing hearts we see thee rise,
The True North strong and free!
From far and wide, O Canada,
We stand on guard for thee.
God keep our land glorious and free!
O Canada, we stand on guard for thee.
O Canada, we stand on guard for thee.

O Canada! Terre de nos aïeux,
Ton front est ceint de fleurons glorieux!
Car ton bras sait porter l'épée,
Il sait porter la croix!
Ton histoire est une épopée
Des plus brillants exploits.
Et ta valeur, de foi trempée,
Protégera nos foyers et nos droits,
Protégera nos foyers et nos droits.

Valerie Woodring Goertzen

Oahu. See **Hawaii** (The islands).

Oak is any of a large variety of trees or shrubs that bear acorns. There are more than 600 species of oaks, all of which grow naturally only in the Northern Hemisphere. Most species of oaks are found in tropical and warm regions. Only a few species grow in Canada and other regions that have short summers and long winters. Oaks thrive in forests throughout the continental United States except for Alaska. They also are important in forests of China, Japan, and central and southern Europe.

Oaks vary widely in size and in the way they grow. Some oaks never become taller than small shrubs. Others reach heights of more than 100 feet (30 meters). Many oaks that grow in warm climates do not lose their leaves in the autumn. They are called *evergreens.* But most oaks found in regions with cold winters are *deciduous*—that is, they shed their leaves each autumn. The leaves of many deciduous oaks turn beautiful colors, such as deep red or golden brown, in early autumn.

In the spring, oaks produce small, yellowish-green flowers. The male flowers, which form in dangling clusters called *catkins,* produce large amounts of pollen. The wind carries the pollen to the female flowers and fertilizes them. Once fertilized, a female flower will become an acorn. The acorn is the fruit of the oak. Acorns vary in length from less than $\frac{1}{2}$ inch (13 millimeters) to more than 2 inches (51 millimeters).

Oaks grow slowly and usually do not bear acorns until they are about 20 years old. But these trees live a long time. Most oaks live for 200 to 400 years.

Oaks are an important source of lumber. Oak wood is heavy, hard, and strong, and it has a beautiful grain. Manufacturers use it for furniture, barrels, and railroad ties. The wood and bark of some oaks contain *tannin,* a bitter substance used in the preparation of leather. Cork comes from the bark of certain oaks. Acorns are an important source of food for wildlife. In the past, many Indians of North America used acorns for food. Today, oaks are grown as ornamental trees worldwide.

North American oaks

More than 300 species of oaks are native to North America. Only about 60 of these grow north of Mexico. Botanists divide oaks into two groups: (1) white oaks and (2) red oaks, sometimes called *black oaks.* The trees in these two groups differ chiefly in the shape of their leaves and in how long it takes their acorns to mature.

White oaks have lobed leaves, and the tips of the lobes are rounded. Many red oaks also have lobed leaves, but these leaves have pointed tips that end in a hairlike bristle. Some red oaks have unlobed, oval leaves with a sharp tip.

The acorns of white oaks form in the spring, mature during the summer, and are shed in the autumn. The acorns of red oaks need two growing seasons to mature. In general, white oak acorns taste less bitter than do red oak acorns.

White oaks thrive throughout deciduous forests of eastern North America. A species that is named the *white oak* is especially common. It is easily recognized by its grayish bark, which forms shinglelike plates about 20 to 30 feet (6 to 9 meters) up the trunk. Its leaves usually have seven or nine lobes. The wood of the white oak makes excellent furniture.

Several other white oaks are important members of eastern deciduous forests. The *post oak* grows in dry soils. It has gray bark and leaves with five lobes. The *overcup oak,* the *swamp chestnut oak,* and the *swamp white oak* are common in swampy areas. The leaves of these three species usually have more than seven lobes. The *bur oak* ranges from the eastern part of the Great Plains east to New Brunswick and Nova Scotia. This species produces large acorns.

Only a few species of white oaks grow in western North America. The *California white oak* is common along streams and in moist valleys of California, where it provides shade for livestock. This oak has leaves with 7, 9, or 11 lobes. It bears long, slender acorns. The *Oregon white oak* is found in river valleys and warm, dry areas from central California to southwestern British Columbia. The leaves of the Oregon white oak resemble those of the California white oak, but it has much plumper acorns. The Oregon white oak also grows as a low shrub along the Oregon coast and in mountainous regions. This oak may be found as high as 4,000 feet (1,200 meters) above sea level.

Red oaks are common in forests of eastern North America. The *northern red oak* grows from the southern Appalachians north to Ontario and Nova Scotia, and west into Arkansas and Missouri. It is often found along with two other red oak species, the *black oak* and the *scarlet oak.* These three species look similar and even experts sometimes confuse them. All three species usually have leaves with seven or nine lobes. But the leaves of black oaks have yellow hairs on the underside. Most scarlet oak leaves have sharply pointed tips and deep notches between the lobes. These oaks are an important source of timber and tannin.

Many red oaks grow only in certain soils or locations. For example, the *blackjack oak* grows in soils that contain much clay. This oak has pear-shaped leaves with golden hairs on the underside. The *turkey oak* is found in sandy soils of the Atlantic coastal plain. Its leaves have deeply notched edges.

Evergreens in the red oak group are often called *live oaks.* The live oak of the Southern States grows in the Gulf and Atlantic coastal plains. Its large, spreading branches are often draped with Spanish moss. In coastal dune areas, these trees grow as shrubs. Live oaks are also common in dry regions of Texas. The *California live oak* grows on hillsides along the southern California coast, where little rain falls during the summer.

A number of shrubby, evergreen oaks grow in dry areas of California and the Southwest. The *California scrub oak* is found in regions that have frequent wildfires. Some reach a height of only 3 to 4 feet (0.9 to 1.2 meters). The roots of this oak have many buds. Following a fire, these buds sprout and grow into new shrubs. The *shrub live oak* is one of several species of shrubby oaks found in the deserts of the Southwestern United States and of Mexico. The shrub live oak is common on mountain slopes.

Other oaks

In Britain and northern Europe, two common deciduous trees are the *English oak* and the *sessile oak,* also called the *durmast oak.* These two species of oaks are easy to tell apart by the way their acorns grow. The acorns of English oaks grow on long stalks. The acorns of sessile oaks attach directly to twigs. Both of these oaks may grow to a height of more than 110 feet (34 meters). Some have lived more than 800 years. The wood of these oaks is used for beams and shipbuilding.

Several deciduous species of oaks also grow in the mountain forests of southern Europe. These include the *Hungarian oak* and the *Pyrenean oak.* Both are used for ornament and shade in gardens worldwide.

Live oaks grow in regions of southern Europe that have mild winters. The *holm oak* looks much like the live oaks of the Southwestern United States. It is an important timber tree and an excellent source of charcoal. The holm oak is grown in parks and along roads throughout the world. The *cork oak* is found chiefly in Spain and Portugal. Cork comes from the bark of this tree.

Many oak species grow in the forests of central and eastern Asia. The *Lebanon oak* is common in mountainous regions of the Middle East. The *Mongolian oak* is an important timber tree in eastern Asia, including Japan. Both of these species can be found in parks and gardens in the United States.

Scientific classification. Oaks are in the beech family, Fagaceae, and make up the genus *Quercus.* The scientific name for the white oak is *Quercus alba,* the northern red oak is *Q. rubra,* the live oak of the Southern States is *Q. virginiana,* and the English oak is *Q. robur.* Norman L. Christensen, Jr.

other nonnuclear sources of energy. In addition, scientists study how the use of various forms of energy affects the environment and human health.

Oak Ridge National Laboratory was established in 1943 as part of the World War II Manhattan Project to build the atomic bomb. The main objective of the laboratory's wartime activities was to develop a process for separating plutonium, an explosive material used in atomic bombs, from uranium. Today, the University of Tennessee and Battelle Memorial Institute, a research and development organization, operate the laboratory under contract with the U.S. Department of Energy.

Toni Grayson Joseph

Oakland (pop. 399,484; met. area pop. 2,392,557) is one of the busiest shipping centers in California. The city lies on the eastern shore of San Francisco Bay, an inlet of the Pacific Ocean. Oakland is 3 miles (4.8 kilometers) across the bay from San Francisco (see **California** [political map]). Oakland was founded after the discovery of gold in California in 1848. The city was named for the oak trees that grew on its hills.

Description. Oakland, the seat of Alameda County, covers about 54 square miles (140 square kilometers). The Oakland metropolitan area covers 1,624 square miles (4,206 square kilometers). Lake Merritt lies in the heart of downtown Oakland. The Lake Merritt Nature Center and Wildlife Refuge, the oldest wildlife refuge in North America, opened in 1870. Jack London Square includes the bay waterfront that was visited frequently by the author for whom it was named.

Attractions in the city include the Oakland Museum of California, the Chabot Space and Science Center, the Oakland East Bay Symphony, and the Oakland Ballet. The African American Museum and Library at Oakland includes letters, diaries, and photographs that share the experiences of blacks in California. Colleges in Oakland include California College of Arts and Crafts, Holy Names College, Mills College, and Patten College. Oakland is home to the Oakland Athletics baseball team of the American League, the Oakland Raiders of the National Football League, and the Golden State Warriors of the National Basketball Association.

Economy. Oakland is a major transportation center. The Port of Oakland is one of the world's busiest ports for container ships. The western terminals of several freight railroad systems are in Oakland. Passenger trains link Oakland with other cities in the United States. The Bay Area Rapid Transit system (BART), a regional rail system, has its headquarters in the city. Air travelers use Oakland International Airport.

A majority of Oakland's workers are employed in service industries. Important economic activities in the city include business and health care services, food processing, and transportation.

Government and history. Oakland has a council-manager form of government. The voters elect a mayor and eight council members to four-year terms. The council appoints a city manager to carry out its policies.

Ohlone, also called Costanoan, Indians lived in what is now Oakland before European settlers arrived. In the 1770's, Spanish explorers and missionaries became the first Europeans to reach the region. In 1820, Luis Maria Peralta, a Spanish soldier, received a land grant that included most of the area that is now Alameda County. By 1849, merchants, loggers, and gold seekers had begun to settle the region. Oakland was incorporated as a town in 1852 and as a city in 1854.

Oakland's population grew rapidly after it was chosen as the western *terminus* (end) of the first transcontinental railroad in 1869. About 65,000 people settled in the city in 1906 after fleeing the San Francisco earthquake. Industrial expansion took place through the 1920's. Many automobile manufacturers and food processing and steel companies were established in the city. Oakland became a major port and shipbuilding center during World War II (1939-1945).

In the 1970's, the city began several urban renewal projects in the downtown area. Construction on Oakland City Center, a complex of office buildings and retail stores, was completed in 1990. Preservation Park, a showplace of historic homes that were moved from other parts of the city, opened in 1991.

In October 1989, a strong earthquake struck Oakland and the surrounding area. As a result of the earthquake, a portion of the upper level of the city's double-decked Nimitz Freeway, or Interstate Highway 880, collapsed onto the lower level. The earthquake caused 43 deaths and extensive property damage in Alameda County. In

Oakland Convention Bureau

Oakland, California, lies on the eastern shore of San Francisco Bay, 3 miles (4.8 kilometers) across the bay from San Francisco. Lake Merritt, *foreground,* is a large saltwater lake in the heart of downtown Oakland.

October 1991, a brush fire in Oakland killed 25 people and caused much property damage.

Redevelopment programs continued into the 2000's. In the late 1990's, businesses and residents began relocating from an overcrowded San Francisco to Oakland.

Betty Marvin

Oakley, Annie (1860-1926), was a famous American sharpshooter who starred in Buffalo Bill's Wild West show for over 16 years. She was assisted by her husband, Frank Butler, and part of her act was to shoot a dime out of his hand or a cigarette out of his mouth. Oakley also could hit a playing card thrown into the air 90 feet (27 meters) away from her. She gained worldwide fame on European tours for such daring deeds as shooting a cigarette held in the mouth of the German Crown Prince Wilhelm.

Annie Oakley was born Phoebe Ann Moses in Darke County, Ohio. She learned to shoot at the age of 8 and helped support her family by killing game for a hotel in Cincinnati. At age 15, she defeated Butler, a professional marksman, in a shooting exhibition. In 1876, she and Butler married. She then adopted the stage name Annie Oakley and took part in shooting exhibitions.

Oakley was only 5 feet (150 centimeters) tall. She was called "Little Sure Shot" by the famous Sioux Indian chief Sitting Bull, who toured briefly with Buffalo Bill's Wild West show. Oakley joined the show in 1885, and Butler became her manager. In 1901, she was injured in a train accident and resigned from the show. She joined a theatrical group and starred in *The Western Girl* (1902). During World War I (1914-1918), she gave shooting exhibitions and instruction to American soldiers.

The popular musical comedy *Annie Get Your Gun* (1946), which has songs by composer Irving Berlin, is loosely based on Oakley's life. It portrays her as an outspoken tomboy. In reality, she was a quiet, simple person who did needlepoint in her free time. Odie B. Faulk

Bettmann Archive

Annie Oakley became famous as one of the world's most accurate shots with pistol, rifle, and shotgun.

Oar. See **Rowing**.

Oarfish is the longest bony fish. It normally measures 16 to 35 feet (5 to 11 meters) long. However, people have reported seeing oarfish more than 55 feet (17 meters) in length. The fish live in *temperate* (mild) and warm seas, normally at depths of 1,000 to 2,000 feet (300 to 610 meters). They have flat-sided, silvery bodies with bright red fins. On the underside of an adult's body, two long pelvic fins end in blade-shaped swellings. These fins resemble the oars of a rowboat, giving the fish its name.

Oarfish have no teeth and feed chiefly on tiny shrimplike creatures called *krill.* The fish swim in a snakelike motion. Occasionally, they travel to the ocean surface. Because of their size and appearance, oarfish probably inspired many "sea serpent" myths. Scientists know little about oarfish because the fish live in deep water and have never been kept in aquariums. John E. McCosker

See also **Fish** (picture: Fish of the deep ocean).

Scientific classification. The oarfish is in the family Regalecidae. It is *Regalecus glesne.*

OAS. See **Organization of American States; France** (France under de Gaulle).

Oasis is a fertile, vegetated area in a desert where underground water comes close enough to the surface for

S. Fiore, Shostal

Irrigation ditches filled with water from deep wells or underground springs support date palms and other crops raised on oases, such as this one in western Africa.

On an artificially created oasis in southern California, *above,* jojoba plants are grown for their seed oil.

wells and springs to exist. Water that occurs at an oasis originally fell as rain or snow in distant mountains or hills. After seeping into the ground, the water slowly filters through the underground rocks toward low places in the desert. It then reappears at the surface to form springs or is shallow enough to be found in wells. Fertile, vegetated areas along permanent streams in deserts are sometimes also called oases.

Soil in desert regions is generally fertile but lacks the moisture to encourage plant growth. Because oases have water, almost all of them are areas of farming and settlement. Some oases are small and can support only a few people, but others are large enough to support millions of people. Wayne Lambert

Oates, *ohts,* **Joyce Carol** (1938-), is an American author. She gives most of her novels and short stories a nightmarish quality and emphasizes sex and violence. However, her most significant subjects are society and the insanity it generates. At the core of her work is a moral vision. Oates has written about 40 books. Some critics argue she would profit from polishing her fiction, but most agree that her pictures of society are accurate.

Oates dramatized the relationship between American society and its people in *A Garden of Earthly Delights* (1967). This novel shows how she believes society treats the poor. *Them* (1969) portrays the violent lives of a poor family in Detroit. *Unholy Loves* (1979) is a comic novel set on an American college campus. *A Bloodsmoor Romance* (1982) satirizes romantic novels of the 1800's.

Often Oates's characters are mentally ill. For example, in *Expensive People* (1968), a teen-ager has difficulty distinguishing reality from fantasy and confesses to his mother's murder, though he may not have committed the crime. The hero of *Wonderland* (1971) and the heroine of *Do with Me What You Will* (1973) have mentally ill fathers. Oates's novella *Black Water* (1992) portrays actions of a politician who belongs to a powerful dynasty and reveals himself to be violent and a victimizer of the narrator.

Oates's stories have been collected in *By the North Gate* (1963), *The Wheel of Love* (1970), *Last Days* (1984), *Raven's Wing* (1986), *Heat* (1991), and *Will You Always Love Me?* (1996). Her *Twelve Plays* was published in 1991. She has also written scholarly essays and poetry. She was born in Lockport, New York.. Victor A. Kramer

Oath is a pledge or promise. The *judicial oath* is probably the most common form. It is used in a court of law, at a deposition, or before a notary public or other judicial officer (see **Deposition; Notary public**). A witness taking a judicial oath swears that all of his or her statements are true. Often the person must lay a hand on the Bible while taking the oath. This gesture means that the person is making a declaration through God. A person swearing to the truth of an affidavit may be given the following oath: "You do solemnly swear that the contents of this affidavit by you subscribed are true, so help you God."

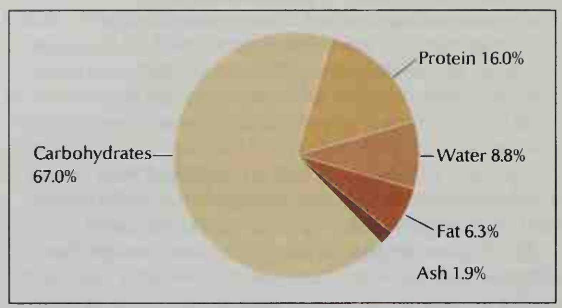
A person who takes an oath in court and then makes a dishonest statement while under oath is guilty of perjury, a crime punishable by a fine or jail sentence.

All of us are familiar with oaths in everyday life. For example, a person who promises to give up a bad habit is said to "take an oath." This kind of oath is called *extrajudicial* because it has no force in a court of law. Oaths taken to show good faith are also extrajudicial.

Affirmation. Some religious groups, such as the Quakers, do not approve of swearing by an oath. They believe in the Bible's command "Swear not at all." When members of such groups testify in court, they take an *affirmation* instead of an oath. The affirmation binds them to the truth as strongly as an oath would. If a person violates an affirmation, he or she becomes guilty of perjury.

Oath of office. Many officials must take a pledge when they enter a public office. This *oath of office* is a promise to carry out the duties of the office honestly and faithfully. According to the Constitution of the United States, the nation's president must take the following oath at the inauguration: "I do solemnly swear (or affirm) that I will faithfully execute the Office of the President of the United States, and will to the best of my Ability, preserve, protect and defend the Constitution of the United States."

All United States officers lower in rank than the president take oaths much like the one above. An officer taking over a state public office promises to protect the state constitution as well as the U.S. Constitution.



In Canada, many government officials take a pledge upon entering public office. Officials appointed to the federal Senate or elected to the House of Commons, and members of the legislative bodies of the provinces, take the following oath: "I do swear that I will be faithful and bear true allegiance to His (or Her) Majesty ..."

Military oaths are taken by people who enter the armed forces. Before a person enters the service, he or she must take the following oath: "I do solemnly swear (or affirm) that I will support and defend the Constitution of the United States against all enemies, foreign and domestic; that I will bear true faith and allegiance to the same; and that I will obey the orders of the President of the United States and the orders of the officers appointed over me, according to regulations and the Uniform Code of Military Justice. So help me God." Members of the armed forces of Canada, the United Kingdom, and other countries take a similar oath. Sherman L. Cohn

Oatmeal is a food product prepared from oats. It is commonly eaten as a cooked breakfast cereal. Oatmeal is made by removing the outer husk of the oat kernel. The *groats,* or inner portion of the kernel, is scoured to remove some of the outer skin. Then it is partially cooked by steaming, and rolled to form flakes.

Oatmeal is a good source of B vitamins and iron. One cup (240 grams) of cooked oatmeal contains about 23 grams of carbohydrates, 5 grams of protein, and 2 grams of fat. One cup is made up of about 85 percent water and has 130 calories. Jane Ann Raymond Bowers

Source: U.S. Department of Agriculture, Agricultural Research Service.

The food value of oatmeal makes it a nourishing breakfast cereal. One cup of oatmeal has about 130 calories.

Oats are an important grain crop. Farmers grow them mainly to feed livestock, but oats also provide nourishing food for many people. The seeds of oat plants are processed and used in such foods as oatmeal, oatcakes, cookies, and ready-to-eat breakfast cereals.

Oats are a cereal grain and belong to the same family of plants as wheat, rice, corn, and barley. Oats have a higher food value than any other cereal grain. They are rich in starch and high-quality protein, and they provide a good source of Vitamin B_1. Some nutritionists believe that the addition of *oat bran* (the seed covering of oats) to the diet helps reduce cholesterol.

About 60 percent of the oats grown in the United States are used as feed for livestock. Oats are the best grain to feed horses. Many farmers use the straw from oats as bedding for their livestock.

Russia is, by far, the leading oat-growing country. The world's annual production of oats totals about 33 million tons (30 million metric tons).

The oat plant has a stem that grows from 2 to 4 feet (60 to 120 centimeters) high. The stem ends in a head called a *panicle,* which consists of many small branches. Each branch ends in a single *spikelet* (flower cluster). The majority of oat plants have from 40 to 50 spikelets. Most spikelets contain two seeds, each enclosed by a husk called the *hull.* The hull must be removed before the seeds can be processed into oatmeal or other food products. The oat seed, called a *groat,* is usually the same color as the hull. Different varieties of oat seeds

Leonard Lee Rue III, Bruce Coleman Ltd.

Oat plants have heads called *panicles.* Each panicle has many flower clusters called *spikelets,* which contain the seeds. Each seed is enclosed by a hull.

Deere & Co.

Planting oats. Many farmers plant oats with a machine called a *grain drill.* Planting takes place in early spring in most regions.

TSW/Chicago Ltd.

Harvesting oats, a farmer may use a *combine.* This machine cuts down the stalks and separates the grain from them.

Leading oat-growing countries

Tons of oats grown in a year

Country	Tons
Russia	6,779,000 tons (6,150,000 metric tons)
Canada	4,073,000 tons (3,695,000 metric tons)
United States	2,557,000 tons (2,320,000 metric tons)
Poland	1,687,000 tons (1,530,000 metric tons)
Australia	1,590,000 tons (1,442,000 metric tons)
Germany	1,553,000 tons (1,409,000 metric tons)
Sweden	1,342,000 tons (1,217,000 metric tons)
Finland	1,262,000 tons (1,145,000 metric tons)
Ukraine	942,000 tons (854,000 metric tons)
China	863,000 tons (783,000 metric tons)

Figures are for a three-year average, 1997-1999.

may be white, yellow, red, gray, or black.

The chief kinds of cultivated oats include *common oats, red oats, side oats,* and *hull-less oats.* Common oats are the type most widely grown in the United States. Red oats have reddish seeds. Side oats have all their branches on one side of the stalk. Hull-less oats, unlike the other types, have loose husks that separate from the seeds during harvesting.

Growing oats. Oats can be grown in a variety of climates and soils. But they grow especially well in areas that have a cool, moist climate and fertile soil. Farmers may add fertilizer to poor soil to increase the yield.

Farmers grow two types of oats, *spring oats* and *winter oats.* Spring oats are planted in early spring and harvested in summer. The date of planting and harvesting depends on the climate of the area. Spring oats account for more than 85 percent of the U.S. oat crop. Winter oats are planted in fall and harvested the next summer. They start growing before the weather turns cold. Growth stops in the winter and begins again in spring. Winter oats are not as hardy as other winter grains, and so they are grown chiefly in areas with mild winters.

Oats are planted either by simply scattering the seeds over the field or by sowing the seeds with a *grain drill.* This machine drops the seeds into furrows and covers them with soil. The seeds are planted in rows about 6 to 7 inches (15 to 18 centimeters) apart and covered with about 2 inches (5 centimeters) of soil. Most farmers use sowing rates of 60 to 90 pounds per acre (65 to 100 kilograms per hectare) of land.

Harvesting oats. Oats are harvested after the plants become dry and yellow and the seeds harden. The grain should not contain more than 12 to 14 percent moisture when harvested. Farmers can take samples of the seed to a grain elevator for a moisture test.

Some oats are grown for hay or *silage.* Silage consists of chopped plant stalks, which are stored in a silo and used to feed livestock during the winter. Oats grown for hay or silage are harvested while the plants are still green and the seeds are soft.

Most farmers harvest oats with a machine called a *combine,* which cuts the stalks and separates the grain from the *chaff* (stiff, strawlike bits surrounding the grain). Before oat grain is made into human food products, the hulls are removed from the seeds at processing plants. Hulls are not removed from grain used as livestock feed. The average yield of oats in the world is about 1,500 pounds per acre (1,700 kilograms per hectare). The United States average is about 1,800 pounds per acre (2,000 kilograms per hectare).

Diseases and insect pests. Various diseases sometimes attack oats and sharply reduce the yield. They include smuts, rusts, septoria, and barley yellow dwarf. Oat crops can also be damaged by such insects as aphids, army worms, cutworms, cereal leaf beetles, and grasshoppers. Aphids are especially troublesome because they spread the barley yellow dwarf disease.

Some farmers use chemical sprays to control diseases and insects. But the best protection comes from planting resistant varieties of oats. Researchers continually develop new varieties that are more resistant to diseases and insects. The new varieties also produce higher yields and better grain. See **Smut; Rust; Aphid; Army worm; Cutworm.** Robert D. Wych

Scientific classification. Oats belong to the grass family, Poaceae or Gramineae, and to the genus *Avena.* Common oats belong to the species *A. sativa.*

Oaxaca, *wah HAH kah,* officially Oaxaca de Juárez (pop. 256,848), is the capital of Oaxaca, a state in southern Mexico. It stands in a rich mining, farming, and forest region (see **Mexico** [political map]). Oaxaca has won fame

for handicrafts. The city's economy relies largely on tourism and the sale of cattle, dairy products, and hardwoods. The ruins of two ancient Indian cities, Mitla and Monte Albán, lie near Oaxaca. Some historians believe the Aztec founded Oaxaca in 1486. But the Zapotec and the Mixtec Indians had lived in the area since the time of the early Christians. The people of colonial Oaxaca produced impressive architecture. Roderic A. Camp

See also **Mixtec Indians; Zapotec Indians.**

Ob River, *ahb, awb,* or *ohb,* is one of the chief rivers of Russia in Asia. It rises in the Altai Mountains of western Siberia and flows northwest for 2,268 miles (3,650 kilometers) before it empties into the Kara Sea through the Gulf of Ob (Obskaya Guba). For location, see **Russia** (terrain map). The river drains about 1,130,000 square miles (2,930,000 square kilometers).

The navigable waterways of the Ob and its tributaries total about 19,000 miles (30,600 kilometers). The lower part of the river is 2 to 4 miles (3 to 6 kilometers) wide, while the estuary averages about 35 miles (55 kilometers) in width. It is blocked with ice from October to June. In summer, the Ob River is an important water route for shipping grain, dairy products, livestock, wool, and meat. Most of these products move to the railways for shipment to the western part of Russia, but some are exported by way of the Arctic Ocean. Craig ZumBrunnen

Obadiah, *OH buh DY uh,* **Book of,** is a book of the Hebrew Bible, or Old Testament, named for an Israelite prophet. The book is the shortest in the Bible, consisting of 21 verses. It was probably composed after the destruction of Jerusalem in 587 or 586 B.C.

The Book of Obadiah has three sections. They deal with the destruction of Edom (verses 1-9), the misdeeds of Edom against Israel (10-14), and the restoration of Israel at the expense of other nations (15-21). Verses 1-9 closely parallel the Book of Jeremiah (49:7-21), but Obadiah appears to preserve the original form of this prophecy. The author's familiarity with prophetic themes, such as "The Day of the Lord" (15-21), places him in the mainstream of late Biblical prophecy. Eric M. Meyers

See also **Bible** (Books of the Hebrew Bible).

Obelisk, *AHB uh lihsk,* is a great, upright, four-sided stone pillar. The sides slope slightly so that the top is smaller than the base. The top is shaped like a pyramid and ends in a point. The Washington Monument in Washington, D.C., is a good example of an obelisk.

Ancient Egyptians erected huge obelisks that were cut from single blocks of granite. Most obelisks had inscriptions in *hieroglyphics* (picture writing). They were often erected in pairs at entrances to temples. Two obelisks, now known as Cleopatra's Needles, were originally at Heliopolis, Egypt. In the 1800's, one was taken to New York City, and the other to London (see **Cleopatra's Needles**). An obelisk from the temple of Luxor, Egypt, is now in Paris' Place de la Concorde.

Obelisks were cut right at the quarry. The ancient Egyptians first made a horizontal, three-sided form by cutting deep trenches all around the form. Then they split away the fourth side either by inserting copper or wooden wedges, or by pounding through the underside with balls of diorite, a hard rock. Finally they polished the obelisk. Still unexplained is exactly how they raised the huge stone pillar to an upright position at its final site. Leonard H. Lesko

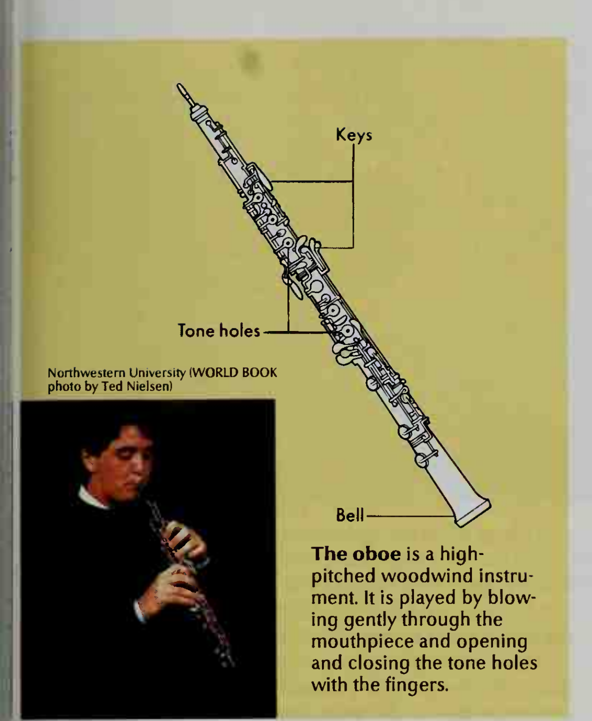
Oberammergau, *OH buhr AH muhr GOW* (pop. 4,664), is a Bavarian village 45 miles (72 kilometers) southwest of Munich in southern Germany (see **Germany** [political map]). It is famous for its performances of the Passion Play, which normally take place every 10 years. This pageant, which attracts thousands of tourists, portrays the suffering and death of Jesus. Residents perform all the parts. The play was first performed in 1634 (see **Passion Play**).



Oberammergau lies in a valley at the foothills of the Bavarian Alps. Bible scenes cover the outside walls of many of the village's buildings. Some of these painted scenes date back to the 1600's. Many people of Oberammergau produce fine wood carvings. Much of the village's income comes from the tourist trade and the sale of carvings. John W. Boyer

Oberlin College, *OH buhr lihn,* is a privately controlled, coeducational liberal arts school at Oberlin, Ohio. It was the first coeducational college in the United States. Oberlin College has a college of arts and sciences and a conservatory of music. Courses lead to bachelor's and a few master's degrees. Oberlin was founded in 1833. In 1841, it became the first United States school to award college degrees to women. See also **Coeducation.** Critically reviewed by Oberlin College

Bavaria Verlag

Oberammergau residents perform the town's famous Passion Play, which portrays the suffering and death of Jesus. The play was first staged in 1634 and is normally presented every 10 years.

Northwestern University (WORLD BOOK photo by Ted Nielsen)

The oboe is a high-pitched woodwind instrument. It is played by blowing gently through the mouthpiece and opening and closing the tone holes with the fingers.

WORLD BOOK illustration by Oxford Illustrators Limited.

Obesity. See Weight control.

Oboe is the smallest and highest-pitched of the double-reed woodwinds. The name comes from two French words: *haut,* meaning *high,* and *bois,* meaning *wood.* The oboe is about 21 inches (53 centimeters) long. It was developed in the 1600's, probably by two French musicians, Jean Hotteterre and André Philidor.

The range of the oboe is almost three octaves. The tone is produced by means of a small double reed. Predecessors of the oboe, called *shawms,* had a raucous, penetrating sound. But today the oboe is known for its smooth and beautiful tone.

The oboe is important in symphony orchestras, concert bands, and small ensembles. Composers who wrote works for the oboe include Ludwig van Beethoven, George Frideric Handel, and Wolfgang Amadeus Mozart. The English horn is an alto oboe, a fifth lower in pitch than the oboe. André P. Larson

See also English horn; Music (Wind instruments). For a recording of the sound of an oboe, see the Oboe article in the CD-ROM version of *World Book.*

Obote, *oh BOH tee,* **Apollo Milton,** *uh PAHL oh* (1926-), served as president of Uganda from 1966 until 1971 and from 1980 until 1985. Obote was born in the Lango district of Uganda. In 1958, he was elected to the Ugandan legislature. In 1960, Obote became leader of the Uganda People's Congress, a new political party he had helped create. He led Uganda, then a British protectorate, to independence in 1962. He then served as the first prime minister of the nation. In 1966, Obote seized full control of the government and declared himself president. The people elected him president in 1967.

As president, Obote abolished the country's separate local kingdoms and ruled with absolute power. He put industry under government control. A military revolt overthrew him in 1971, and he went into exile. Idi Amin Dada, who led the revolt, ruled Uganda until 1979. In 1980, Obote returned to Uganda and was elected president. Military leaders again overthrew him in 1985, and he went into exile. Robert I. Rotberg

See also Uganda (History).

Obregón, *OH bray GAWN,* **Álvaro,** *AHL vah roh* (1880-1928), was president of Mexico from 1920 to 1924. He succeeded Venustiano Carranza as president, after Carranza was killed in a revolt led by Obregón. As president, Obregón distributed some land among the peasants, built many schools, and supported a strong labor union movement. He was reelected president in 1928 but was assassinated before he could take office.

Obregón was born in the municipal district of Navojoa in Sonora. In 1912, he raised a force of Yaqui Indians and defended President Francisco Madero during a revolution against the government. In 1913, Victoriano Huerta murdered Madero and seized the presidency. That same year, Obregón joined Venustiano Carranza in a revolt against Huerta and, in 1914, fought Pancho Villa to help Carranza become acting chief of Mexico. Obregón later opposed Carranza after Carranza refused to support his efforts to become president. W. Dirk Raat

See also Mexico (Economic and social changes); Carranza, Venustiano; Villa, Pancho (with picture).

O'Brien, Lawrence Francis (1917-1990), served as postmaster general of the United States from 1965 to 1968. He helped modernize the postal system and turn the Post Office Department into a semiprivate corporation. From 1961 to 1965, he was a special assistant in charge of congressional relations to Presidents John F. Kennedy and Lyndon B. Johnson. O'Brien served as chairman of the Democratic National Committee in 1968 and 1969, and from 1970 to 1972. O'Brien served as commissioner of the National Basketball Association (NBA) from 1975 to 1984. He was born in Springfield, Massachusetts.
James I. Lengle

O'Brien, Robert C. (1918-1973), was the pen name of Robert Leslie Conly, an American author of children's books. O'Brien won the 1972 Newbery Medal for *Mrs. Frisby and the Rats of NIMH* (1971). This novel tells about a widowed mouse who willingly faces many dangers to save her invalid son. She receives aid from superintelligent rats who have escaped from a laboratory at the National Institute of Mental Health (NIMH).

O'Brien was born in New York City. His first children's book was *The Silver Crown* (1968). His last book, *Z for Zachariah,* a mystery story for young readers, was published in 1974, after his death. Nancy Lyman Huse

Obscenity and pornography are terms used to designate written, recorded, or pictorial material—including motion pictures—that many people consider indecent and thus find offensive. The term *obscenity* can also refer to any language or behavior believed to corrupt public morals. The term *pornography* refers chiefly to written or sexually explicit pictorial material intended primarily to cause sexual stimulation. Some people use the term to refer to written or pictorial material that glorifies violence against women or degrades women. In many cases, however, the terms *obscenity* and *pornography* are used interchangeably.

In the United States, most states and cities have laws against publishing, distributing, or selling obscene

materials. There are also federal laws against the interstate sale and distribution of such material and against the presentation of obscene material on radio or television. But these laws have been hard to enforce, in part because it is difficult to determine what is obscene according to the law.

The nature of obscenity and pornography and the laws governing them have been a continuing source of controversy. Some people are convinced that the distribution of pornographic material corrupts public morality. Others focus on the extent to which some printed or photographic material portrays violence against women —and the degradation of women—as appropriate behavior. From this perspective, the problem is not in the portrayal of sex, but in the portrayal of women as existing for the sexual satisfaction of men. Others believe existing antiobscenity laws and proposed antipornography laws violate the rights of free speech and press guaranteed by the First Amendment to the U.S. Constitution.

Congress passed the first federal law against obscenity as part of the Tariff Act of 1842. This law made it illegal to bring what it called "indecent and obscene" material into the country. The Comstock Law, passed in 1873, prohibited the mailing of indecent materials.

In 1957, in the case of *Roth v. the United States,* the Supreme Court ruled that freedom of speech and the press—as guaranteed by the First Amendment—restricted prosecution to only those materials that a court had determined to be legally obscene. But the Supreme Court provided only loose guidelines for the definition of legally obscene material.

In 1973, in the case of *Miller v. California,* the Supreme Court held that material could be considered legally obscene only if (1) the average person, applying contemporary community standards, would find that the material, taken as a whole, appeals to the *prurient* (sexually arousing) interest; (2) the material shows, in a clearly offensive way, sexual conduct specifically described in the applicable law; and (3) the material lacks serious literary, artistic, political, or scientific value, when evaluated in accordance with national standards. In 1974, in *Jenkins v. Georgia,* the Supreme Court unanimously determined that local standards play a very limited role in the determination of what is to be considered obscene. Today, as a result of *Jenkins v. Georgia, Miller v. California,* and other cases, obscenity prosecutions are rare.

A national Commission on Obscenity and Pornography reported in 1970 that it found no reliable evidence that pornography caused crime among adults or delinquency among young people. The commission recommended repeal of all laws prohibiting the sale of pornography to consenting adults. But it also recommended that each state adopt laws against the sale of obscene pictorial material to young people. In 1986, however, the Attorney General's Commission on Pornography determined that a relationship existed between sexually violent or degrading materials and the amount of sexual violence in society. It also recommended increased prosecution of cases dealing with *child pornography*—that is, pornographic materials that involve photographs of children.

In other countries. Many nations have antiobscenity laws. In some, including Ireland and Italy, such laws are strictly enforced. In Canada, antiobscenity groups have fought for years for stricter laws and stricter enforcement. Many members of these groups seek recognition of the harm resulting from materials that endorse sexual violence against women. But some nations have repealed their obscenity laws. In the late 1960's, for example, Denmark dropped all legal barriers against pornography for adults. Frederick Schauer

Observatory is a research institution where astronomers study planets, stars, galaxies, and other celestial objects. An observatory has at least one telescope or other kind of observation device. Most such devices are housed in structures built on the ground, but observation equipment is also used underground, in airplanes, and in satellites. Certain satellites that house telescopes are also known as observatories.

The term *observatory* can also refer to certain ancient structures that people probably used to keep track of important days of the year. One such structure, Stonehenge, in Wiltshire, England, consists of large stone slabs set in the ground. People may have used Stonehenge to determine, for example, when summer began. At the beginning of summer, the sun would rise above an imaginary line between a certain pair of slabs.

Observatories with telescopes

Where observatories are built. Earth's atmosphere influences the selection of sites for telescopes. Telescopes work with visible light and other forms of *electromagnetic radiation* sent out by objects in space. The radiation travels in waves, and the forms differ in *wavelength,* distance between successive wave crests. The forms of electromagnetic radiation are—from the shortest to the longest wavelength—gamma rays, X rays, ultraviolet rays, visible light, infrared rays, and radio waves.

The atmosphere blocks gamma rays and X rays as well as certain wavelengths of infrared and ultraviolet rays. Telescopes built to work with such radiation must therefore operate aboard satellites. The atmosphere also partially blocks other infrared and ultraviolet wavelengths. However, telescopes on high mountains can detect some infrared and ultraviolet rays. Telescopes in aircraft that fly at high altitudes can observe more infrared wavelengths. To "see" the remaining infrared and ultraviolet wavelengths, a telescope must operate in space.

Visible light and radio waves pass readily through the atmosphere. So *optical* telescopes—those that detect visible light—and radio telescopes can be on the ground.

Ground-based observatories. Optical telescopes are built on mountaintops or high plains to avoid air pollution, illumination from city lights, and the distorting effect of the atmosphere. The distorting effect, which also causes the stars to twinkle, blurs images of stars and

Mauna Kea, on the island of Hawaii, has some of the largest optical telescopes in the world. The two spherical structures in the left center of this photo are the W. M. Keck Observatory of the United States. In the cylindrical building beside them is the Subaru telescope of Japan.

other heavenly objects. A high-altitude location will also more likely offer a large percentage of clear nights because it is above low-lying clouds.

Radio telescopes must be shielded from radio waves that are used for communications. So some radio observatories are built in valleys so that the surrounding hills shield them. Others are on mountaintops or high plains.

One of the chief mountain sites is Mauna Kea, a volcano that rises 13,796 feet (4,205 meters) above sea level on the island of Hawaii. Major optical telescopes on Mauna Kea include Keck I and Keck II, operated by a partnership of the University of California and the California Institute of Technology (Caltech); and Subaru, operated by Japan's National Astronomical Observatory.

A radio telescope known as the Robert C. Byrd Green Bank Telescope (GBT) is in a valley in Green Bank, West Virginia. A group of 27 radio telescopes called the Very Large Array (VLA) stands on a high plain near Socorro, New Mexico. The National Radio Astronomy Observatory of the United States operates the GBT and the VLA.

Airborne observatories. From 1975 to 1995, the Gerard P. Kuiper Airborne Observatory (KAO) made observations at infrared wavelengths. The KAO was a modified C-141 cargo plane equipped with a telescope whose light-gathering mirror was 36 inches (91 centimeters) across. The craft flew at altitudes as high as 45,000 feet (13.7 kilometers). The National Aeronautics and Space Administration (NASA) of the United States operated the KAO.

Satellite observatories. The best-known satellite observatory is the Hubble Space Telescope, launched in 1990 to observe infrared, visible, and ultraviolet radiation. It was the first of NASA's four "Great Observatories" to go into orbit. The second was the Compton Gamma Ray Observatory, which circled Earth from 1991 to 2000. The third is the Chandra X-ray Observatory, launched in 1999. The last of the four, the Space Infrared Telescope Facility, was due to be launched in 2003.

How observatories are operated. The staff of a ground-based, telescopic observatory consists of astronomers, engineers, technicians, telescope operators, computer programmers, optics experts, and administrators. But astronomers who are not on the staff do most of the research.

Teams of astronomers share time on the major telescopes. Teams wishing to use a telescope must submit research proposals to a special committee. The committee approves certain proposals and divides up the time that is available on the telescope. In general, a given team will have limited access—often only a few nights of use a year.

Large ground-based telescopes are so complex that a telescope operator is usually present at the observatory. However, an astronomer does not necessarily have to go to the observatory to use one of its telescopes—the astronomer can work via computer links. Computer-controlled light detectors mounted on the telescope convert the results of the observations to electric signals, so the data can be transferred over the links. Orbiting observatories are operated by radio commands sent from a control center on the ground.

Other kinds of observatories

Neutrino observatories detect subatomic particles called *neutrinos* that come from space. Neutrinos rarely interact with other kinds of matter, so a neutrino observatory must use a huge quantity of matter as a neutrino target. Neutrino observatories are built beneath Earth's surface because large numbers of other particles would interact with a target on the surface.

The target at the Sudbury Neutrino Observatory (SNO) in Greater Sudbury, Ontario, is 1,100 tons (1,000 metric tons) of *heavy water* held in an underground tank. Heavy water is slightly heavier than ordinary water because it contains *deuterium,* a hydrogen atom that weighs more than the ordinary hydrogen atom. SNO is operated by Sudbury Neutrino Observatory Institute, an organization with representatives from Canada, the United Kingdom, and the United States.

Gravitational observatories. Astronomers are building ground-based observatories to detect *gravitational waves.* According to the general theory of relativi-

ty announced by the German-born American physicist Albert Einstein in 1915, gravity can travel in waves. However, such waves have not yet been directly detected.

To detect them directly, the observatories will use objects that are large enough to be measurably affected by them. The Laser Interferometer Gravitational-Wave Observatory (LIGO) will have three detectors, two in Hanford, Washington, and one in Livingston, Louisiana. Each detector will use two metal tubes, each $2\frac{1}{2}$ miles (4 kilometers) long. When a wave passes through the tubes, it will change their lengths. A laser device will detect the changes. Caltech and the Massachusetts Institute of Technology will operate LIGO. Kevin Krisciunas

Obsessive-compulsive disorder is a common mental illness in which people feel burdened by unwanted thoughts or forced to repeat troublesome actions. Unwanted thoughts, called *obsessions,* often include unreasonable fear of dirt or germs. Another common obsession involves fear of losing control and hurting oneself or others. Many patients also feel a need to perform repeated actions, called *compulsions,* to prevent harmful events. Some wash their hands excessively to avoid infection. Unreasonable repetition of everyday routines—for example, checking that faucets or stoves are turned off—is also common.

Most people have certain routines and habits that they find comforting. For example, a person may like to get dressed or prepare for bed in a certain way. But most people can change their routines when the need arises. People with obsessive-compulsive disorder feel trapped and unable to change, even though they know that their obsessions and compulsions are unrealistic.

Many experts believe that obsessive-compulsive disorder involves an imbalance in *serotonin,* one of the brain's most important messenger chemicals. Doctors may treat the disorder with medicines that correct serotonin levels. People may also be helped by behavior therapy, which teaches patients ways to resist their unreasonable thoughts and actions. Donald W. Black

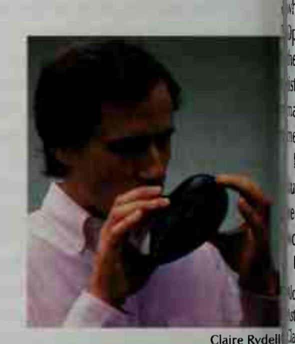
Obsidian, *ahb SIHD ee uhn,* is a natural glass formed when hot lava flows onto the surface of the earth and cools quickly. Obsidian has the same chemical composition as granite, but it is quenched to make glass rather than cooled slowly to form crystals. Most obsidian is black, or black with red bands. It is brittle. Indians used it to make arrowheads and knives. See also **Granite; Igneous rock.** Marilyn M. Lindstrom



Obstetrics and gynecology, *ahb STEHT rihks, GY nuh KAHL uh jee,* are branches of medicine that deal with women's health. *Obstetrics* is concerned with pregnancy, childbirth, and the six-week period following delivery. Doctors who practice obstetrics are called *obstetricians. Gynecology* deals with diseases of the female reproductive organs. Doctors who practice gynecology are called *gynecologists.*

During a woman's pregnancy, an obstetrician is responsible for the health of both the mother and the *fetus* (unborn child). The obstetrician must take special care to avoid harming the fetus when treating diseases in the mother. During childbirth, the obstetrician helps deliver the baby. Thereafter, the obstetrician examines the mother periodically to make sure she recovers from the changes that occurred in her body during pregnancy.

A gynecologist deals with disorders involving the uterus, the ovaries, the fallopian tubes, and other organs of the female reproductive system. Such disorders may be present at birth, or they may result from infections, tumors, injuries, or improper balances of *hormones* (body chemicals). The gynecologist may prescribe drugs, use radiation, or perform surgery to treat the patient. Gretajo Northrop

Ocarina, *AHK uh REE nuh,* is a small wind instrument of the whistle type. It is made of molded clay or plastic, and is shaped like an elongated egg or a sweet potato, which it is often called in the United States. It has a mouthpiece through which air is blown and 8 to 10 holes that sound a simple scale. Its tone is pleasant and soft. An Italian named Giuseppe Donati developed the standard Western ocarina in the 1860's, but forms of the ocarina were known in ancient China. Varieties of the ocarina are often used to play folk music. André P. Larson

Claire Rydell

Ocarina

O'Casey, Sean, *shawn* (1880-1964), was perhaps the greatest Irish playwright of his time. Born in the Dublin slums and largely self-educated, he gained fame when Dublin's Abbey Theatre staged three of his plays—*The Shadow of a Gunman* (1923), *Juno and the Paycock* (1924), and *The Plough and the Stars* (1926). Each play deals with the violence in Ireland from 1916 to 1924, during and after its fight for independence from England. O'Casey showed egotism, slogans, and abstract ideals such as patriotism as the enemies of life and happiness. The plays are full of colorful characters and speech and are written in a vivid, realistic style.

O'Casey left Ireland for England in 1926, after *The Plough and the Stars* provoked rioting during its opening week. Some of the audience thought the play slandered Ireland's patriots and womanhood. O'Casey broke with the Abbey Theatre in 1928 after it refused to stage his play *The Silver Tassie.* Like his earlier work, this play was antiwar in tone, and shows war as the destroyer of individuality and heroism. The play also developed expressionistic tendencies found in O'Casey's earlier work. Symbolism and expressionism became more important in O'Casey's later plays.

Most of the plays O'Casey wrote during the 1930's and ɪarly 1940's have revolutionary heroes and call for a radiɪal transformation of society. These works include *Purɔle Dust* (published in 1940) and *Red Roses for Me* (pubɪshed in 1942).

O'Casey returned to Irish themes late in his career. He ɔresented an Ireland that had exchanged British domiɪation for domination by the Roman Catholic Church of reland and the new commercial class. Plays of this periɔd include *Cock-a-doodle Dandy* (1949), *The Bishop's 3onfire* (1955), and *The Drums of Father Ned* (completed n 1958). O'Casey's most important nondramatic work is ɪn autobiography in fictional form. He died on Sept. 18, 964. Edward Hirsch

)ccam, William of. See William of Ockham.

)ccultism, *uh KUHL tihz uhm,* is a term that refers to a vide range of beliefs and practices involving magic or orces outside the natural world. Occultism includes asrology, fortunetelling, magic, and *spiritualism*—the beɪef that spirits of the dead communicate with the living. 'eople who believe in occultism consider it to be based ɔn hidden knowledge that ordinary people do not have.

Some scientists reject all occult practices. Others beɪeve in mind reading and certain other occult powers, vhich they call *paranormal* (outside normal awareness).)pinion regarding some practices has changed through he years. Until the late 1800's, for example, most scienists considered hypnotism an occult practice. However, nany scientists accept hypnotism today and use it in nedicine and psychology.

Belief in occultism is most common in isolated, noninlustrial societies. But since the mid-1900's, there has ɪeen a widespread revival of occultism in the Western vorld. Christopher McIntosh

)ccupancy, *AKH yuh puhn see,* is a legal method by vhich a person or nation acquires title to something hat no one else owns. Occupancy was first recognized ɔy the civil law of ancient Rome. It later became part of nglish common law.

To gain title to a thing by occupancy, a person or naɪon must take possession of the thing with the intention ɪf keeping it. In some places, a person who captures a vild animal and keeps it may become the animal's ownr. A person who finds lost property can gain title to it if he person who lost the property fails to reclaim it beɔre a certain time has passed. English settlers claimed 3ermuda for England by occupancy in 1609, when the slands had no other inhabitants. Linda Henry Elrod

)ccupation. See Careers.

)ccupational disease. See Disease (Environmental nd occupational diseases).

)ccupational medicine is the branch of medicine hat deals with diseases caused by hazards that people encounter on the job or at their workplace. Doctors in this specialty may work independently, or for a hospital or clinic. Others may have jobs with a large company, providing care for its employees. Although some specialists in occupational medicine treat workplace-related injuries and illnesses, most focus on preventing these problems by modifying the work environment.

Two important tools of occupational medicine are *epidemiology* and *toxicology.* Epidemiology is the science of investigating the causes, distribution, and control of disease by studying groups of affected people. Toxicology is the study of poisonous materials and their effects on living things.

Doctors who practice occupational medicine are always on the alert to identify diseases caused by chemicals or industrial processes. For example, one doctor noticed that several workers with a rare type of liver cancer worked with vinyl chloride, a gas used to make plastic. Using epidemiologic techniques, he showed that the workers' exposure to vinyl chloride caused this cancer. Companies worldwide took steps to prevent the disease by reducing workers' exposure to the gas.

By using knowledge of toxicology, occupational medicine specialists try to predict the diseases that chemicals could cause. Then they tell companies that use the chemicals how to protect their employees. These employees undergo periodic testing to ensure that they are not getting sick from their exposure at work. Because the doctors identify the hazards early, companies can take steps to prevent disease by reducing exposure and monitoring workers' health.

This focus on the health of both the individual and the group is a special feature of *preventive medicine,* the branch of medicine concerned with prevention of disease. This combined approach distinguishes an occupational medicine specialist from the other medical specialists who may treat workplace-related illnesses and injuries. Specialists in occupational medicine can save lives by identifying the cause of a disease and then sharing their discovery.

Occupational medicine is a recognized specialty in many developed countries, and the demand for specialists is great. A doctor who decides to specialize in occupational medicine receives advanced training in toxicology, epidemiology, statistical methods, and public health. The doctor can then become certified by demonstrating the level of professional competence required by national authorities. Shirley A. Conibear

Occupational Safety and Health Administration (OSHA) is an agency of the United States Department of Labor that promotes safe and healthful working conditions. OSHA's chief responsibility is the development and enforcement of job safety and health regulations. The agency also works to educate employers and employees about industrial hazards.

OSHA regulations deal with fire prevention, protective garments and railings, and many other safety matters. The rules also establish maximum levels of exposure to asbestos, lead, and other substances that could endanger the health of workers. OSHA inspectors check factories and other sites for violations, and employers who fail to make required changes are fined.

The agency encourages the states to develop their

own health and safety programs to replace OSHA itself. Many states have programs approved by the agency. The federal government pays half the cost of such programs.

OSHA was established by the Williams-Steiger Occupational Safety and Health Act of 1970 and began operating in 1971. Many leaders of both business and labor have criticized the agency's performance. Executives complain that OSHA demands too much paperwork and too many costly changes that do not increase safety. Labor leaders charge that the agency lags in developing new regulations and fails to enforce existing ones. To improve the agency's performance, OSHA began additional training programs for inspectors and planned more efficient procedures. Harvey Glickman

See also National Institute for Occupational Safety and Health.

Occupational therapy is a form of treatment that uses everyday activities to help people with illnesses or disabilities recover, develop, or maintain practical skills. Doctors often recommend occupational therapy for patients with health problems that interfere with their ability to perform daily tasks at home, school, or work. For example, a person who uses a wheelchair may need to learn how to get around in the kitchen and prepare a meal from a sitting position. A person who has lost sight or the use of an arm or leg may need to learn new ways to bathe or dress. Occupational therapy is often called *curing by doing* because patients improve their own physical and mental well being by carrying out activities themselves.

Professionals called *occupational therapists* plan and supervise treatment activities for their patients. *Occupational therapy assistants* work under the supervision of an occupational therapist and do much of the hands-on work with patients, helping them learn and practice skills. Occupational therapists and assistants work in such settings as hospitals, rehabilitation centers, mental health centers, schools, facilities for older adults, and day care centers. Many occupational therapists also provide treatment in people's homes.

American Occupational Therapy Association, Inc.

Occupational therapy may involve the use of games or other physical activities that help disabled children strengthen their muscles and improve coordination.

How occupational therapy helps patients

An occupational therapist first needs to evaluate a patient's health problems, background, and interests. The therapist uses this information to plan an individual program that will meet each patient's needs and make the most of each patient's abilities.

Helping people with physical disabilities. People who have a serious illness or injury may lose strength and coordination. For example, a person with multiple sclerosis (MS) may become weak and have difficulty balancing because the disease damages the nerves that control muscles. An occupational therapist will help an MS patient learn activities that preserve strength and maintain the greatest possible range of useful activities. In addition to teaching activities, the therapist may make a splint for the person's hand, arm, or leg to prevent weakened muscles from stretching or shrinking.

Occupational therapy plays a vital part in helping people with permanent disabilities, such as blindness or the loss of a limb. A blind person might learn to travel to a commercial district and shop alone. The therapist may help a patient find resources, such as special tools or equipment, to replace lost skills or functions. For example, someone whose arm or leg was amputated might learn to drive a specially equipped car.

Specially designed computers enable people with spinal cord injuries, blindness, hearing impairment, or cerebral palsy to communicate, operate household equipment, and find and hold a job. An occupational therapist may suggest rearranging furniture or equipment in a patient's home to make him or her more independent. The therapist may also recommend structural changes, such as widening doorways, lowering sinks and counters, and installing automatic door openers for people who use wheelchairs.

Occupational therapy helps people with chronic illnesses, such as emphysema or heart disease, redirect their interests into activities within their physical limits. For example, someone recovering from a heart attack might substitute walking for tennis.

Occupational therapy also aids people who become injured at work or develop health problems that affect their ability to do their jobs. Modifications to an employee's work environment or job responsibilities may enable the person to return to work and avoid reinjury.

Occupational therapy can also aid the growth and development of children. Many children receive treatment at school. Occupational therapists help these children interact with others, develop self-confidence, and take full advantage of opportunities in the classroom and playground. Therapists also work closely with the children's family members and teachers.

Occupational therapy for children often includes playing with toys or participating in games. A child with learning disabilities may have difficulty recognizing colors and shapes. He or she may play games that involve matching objects of different size, shape, texture, and color. A child with cerebral palsy may have difficulty

© Hank Morgan, Photo Researchers

Occupational therapists work with patients to help them develop or maintain skills needed for living and working. Here, a therapist works with a patient in a simulation of a supermarket to help her learn how to shop from a wheelchair.

dressing. An occupational therapist might provide the child with a toy that features zippers and buttons. Playing with the toy helps the child develop the skills needed to get dressed.

Helping people with mental illness. Occupational therapists also help people who have mental and emotional illnesses, such as anxiety, depression, and schizophrenia. These illnesses may interfere with a person's ability to cope with daily life. People with mental illness may need to learn how to plan their day, how to manage stress, or how to communicate effectively with family and co-workers. A therapist can help a patient identify the most significant problem areas in his or her life. Together, the therapist and patient can plan a program of strategies to help the patient gain a sense of accomplishment and satisfaction. For example, a person who is depressed might create a daily schedule of goals and activities and check off those that have been completed.

History

Occupational therapy as a profession dates back only to the early 1900's, but people have long known that work and other activities speed recovery from illness or injury. In A.D. 172, the Greek physician Galen said, "Employment is nature's best medicine and essential to human happiness."

During the late 1700's, physicians in several countries began to prescribe useful activities as treatment for patients with mental illnesses. These doctors included Philippe Pinel in France, Johann Christian Reil in Germany, and Benjamin Rush in the United States. As early as 1798, medical professionals at the Pennsylvania Hospital for the Insane in Philadelphia taught patients such skills as carpentry, needlework, and shoe repair.

Modern occupational therapy developed from a nursing course called Invalid Occupations. This course was first offered to student nurses in 1906 by Susan E. Tracy, a Boston nurse. American architect George E. Barton originated the term *occupational therapy.* He himself received this form of treatment after one of his feet was amputated. The need to help disabled veterans of World Wars I (1914-1918) and II (1939-1945) stimulated the growth of occupational therapy. The World Federation of Occupational Therapists was established in Liverpool, England, in 1952.

Careers

Anyone who is interested in a career as a professional occupational therapist must first earn a bachelor's or master's degree in occupational therapy from an accredited college or university. Accredited programs include courses in biology, psychology, sociology, and occupational therapy theory and practice. All programs require students to complete a period of supervised clinical training. Most teaching, research, and administrative positions in occupational therapy require a master's or doctor's degree.

A person who wants to become an occupational therapy assistant must complete an associate degree program. Associate's programs also include academic coursework and supervised clinical training.

Upon completion of the program, graduates must pass a certification examination. Assistants must also take an exam. The American Occupational Therapy Association, Association of Occupational Therapists in Ireland, British Association of Occupational Therapists, Canadian Association of Occupational Therapists, Singapore Association of Occupational Therapists, and similar professional groups in other countries can provide information on training programs and careers.

NASA/Goddard Space Flight Center & ORBIMAGE/SeaWiFS Project

Ocean waters cover most of Earth's surface. This satellite view shows the Indian Ocean, partly bordered by Africa, Asia, and Australia, and below it the Southern Ocean surrounding Antarctica.

Ocean

Ocean is the great body of water that covers nearly 71 percent of Earth's surface. People also call it the sea. The ocean serves as a source of food, energy, minerals, and recreation. Ships sail the ocean to carry cargo between continents. The sea also plays a major role in Earth's climate system by regulating the air temperature and by supplying the moisture for rainfall. If there were no ocean, life could not exist on our planet.

The ocean contains about 97 percent of all the water on Earth. Most of the remaining water occurs frozen in ice sheets and other ice formations. The rest is underground, in the air, or in such bodies of water as lakes and rivers.

The bottom of the ocean has features as varied as those on land. Huge plains spread across the ocean floor, and long mountain chains rise toward the surface. Volcanoes erupt from the ocean bottom, and trenches and valleys plunge to great depths.

Scientists called *oceanographers* work to discover the

Dana R. Kester, the contributor of this article, is Professor of Oceanography at the University of Rhode Island.

ocean's secrets. They study how the ocean moves and how it affects the atmosphere. They investigate the chemical composition of seawater and monitor the forces that shape the sea floor. They also study how organisms live in the sea and how people affect the ocean.

The world ocean

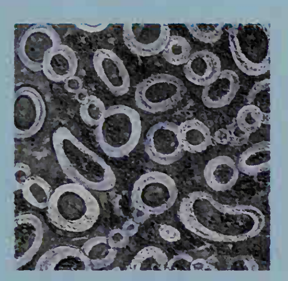
The ocean forms one great connected body of water often called the *world ocean* or the *global ocean.* Geographers and oceanographers divide the world ocean into five major parts. They are the Pacific Ocean, the Atlantic Ocean, the Indian Ocean, the Southern Ocean, and the Arctic Ocean. Each ocean includes smaller bodies of water called *seas, gulfs,* or *bays,* which lie along the ocean margins. For example, the Caribbean Sea and the Mediterranean Sea are part of the Atlantic, and the Bering Sea and the South China Sea are part of the Pacific. The word *sea* also refers to the ocean in general.

Area. The world ocean covers about 71 percent of Earth's surface. Most of the ocean lies in the Southern Hemisphere—that is, south of the equator. The Southern Hemisphere consists of about 80 percent ocean, and the Northern Hemisphere about 60 percent.

The Pacific Ocean ranks as the largest ocean by far. It covers about 66 million square miles (171 million square kilometers)—about one-third of Earth's surface. Near the equator, the Pacific stretches about 11,000 miles (17,700 kilometers) from Panama to the Malay Peninsula. North and South America border the Pacific on the east, and Asia and Australia lie to the west. To the north, the Bering Strait links the Pacific with the Arctic Ocean. See **Pacific Ocean.**

The Atlantic Ocean covers about 34 million square miles (88 million square kilometers). Europe and Africa lie east of the Atlantic, and North and South America lie west. See **Atlantic Ocean.**

The Indian Ocean has an area of about 26.6 million square miles (69 million square kilometers). Africa lies to the west. Australia and Indonesia lie to the east. Asia borders this Ocean on the north. See **Indian Ocean.**



The Southern Ocean covers about 8.5 million square miles (22 million square kilometers). It surrounds the continent of Antarctica. See **Southern Ocean.**

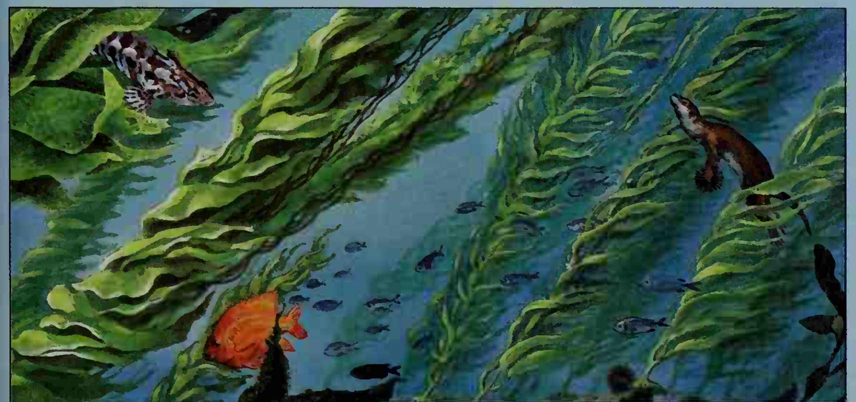
The Arctic Ocean covers about 4.6 million square miles (12 million square kilometers). It is bounded by Asia, Europe, and North America. See **Arctic Ocean.**

Depth. The world ocean has an average depth of 13,000 feet (4,000 meters), but parts of the ocean plunge

Interesting facts about the ocean

WORLD BOOK illustrations by John Eggert and Robin Bouttell, WildLife Art Limited

Life began in the ocean according to most scientists. Fossils of one sea creature, *pictured here,* which belongs to a group of soft-bodied animals called mollusks, show that the organism has remained unchanged for over 500 million years.

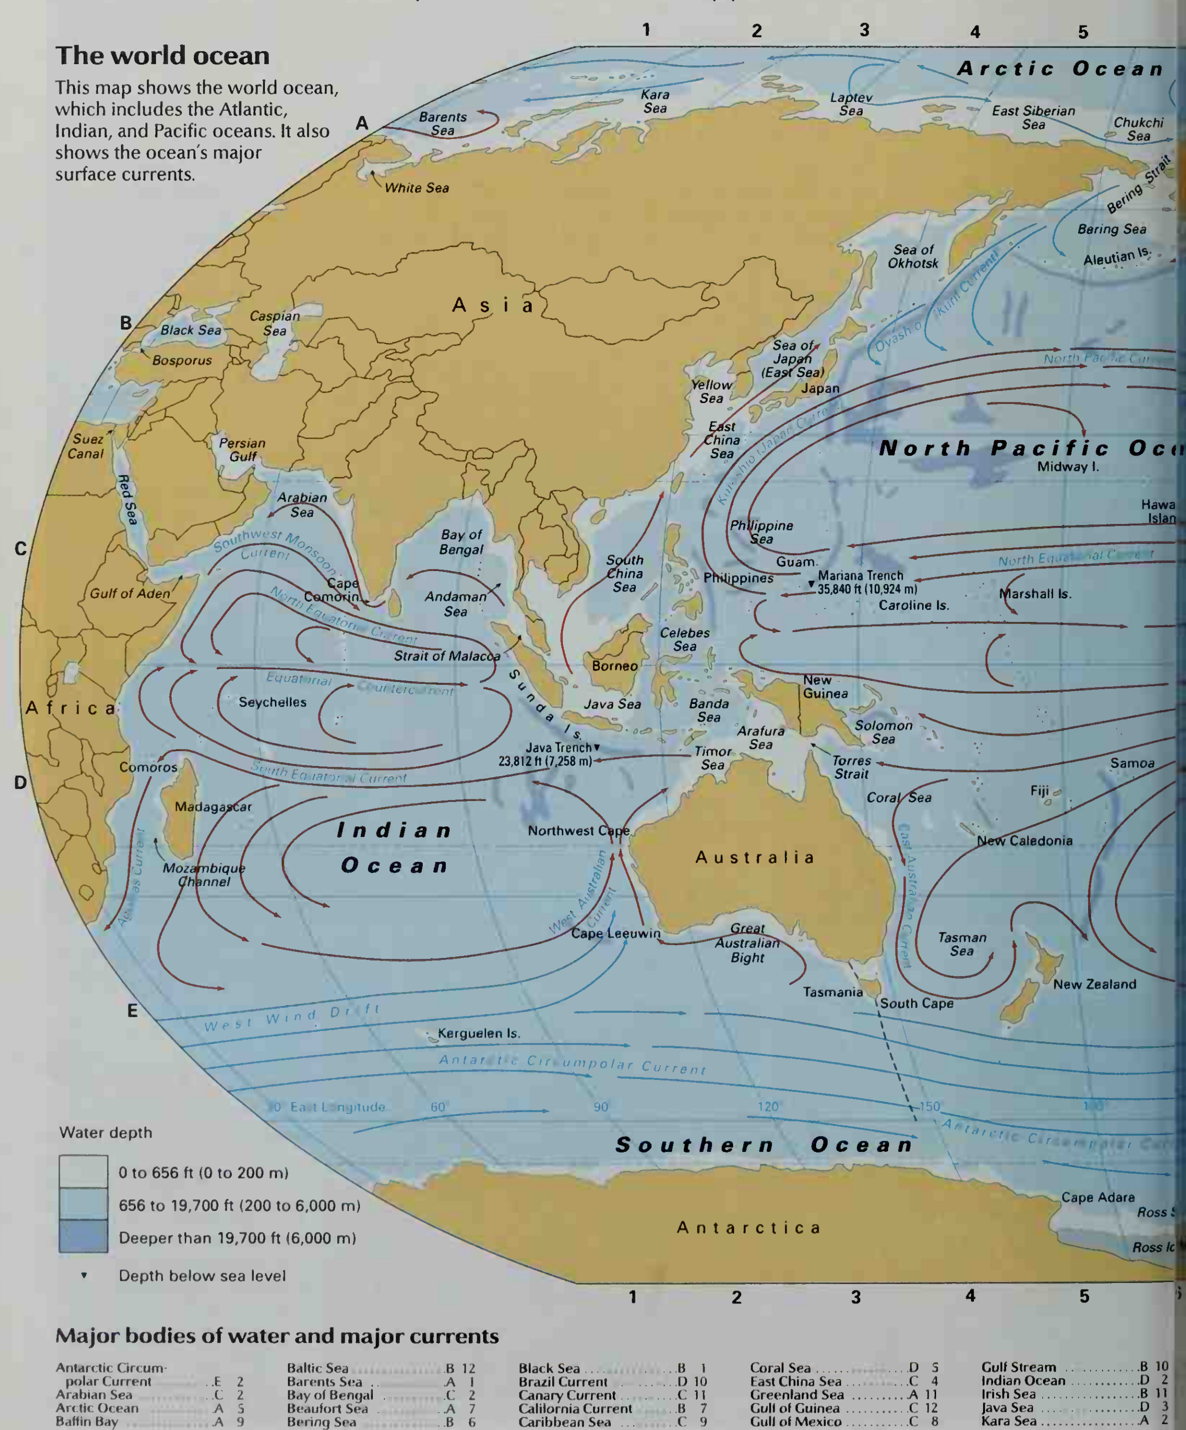


The world ocean would rise about 200 feet (60 meters) if the Greenland and Antarctic ice sheets should suddenly melt. New York City would be submerged, with only the tops of the tallest buildings above water.

There is a bit of "ocean" inside us. The body of an adult male contains about 19 quarts (18 liters) of salt water. The composition of this fluid is similar to seawater.

The Atlantic Ocean's floor spreads about 0.6 inch (1.5 centimeters) yearly, widening the ocean basin. The Pacific floor spreads about 5 inches (13 centimeters) yearly. The edges of this floor sink under continents, so the basin does not widen.

A *tsunami*—a powerful wave caused by an earthquake or underwater landslide—can reach a speed of 600 miles (970 kilometers) per hour and travel across an entire ocean.



Giant kelp, a large seaweed, may grow up to 200 feet (60 meters) long. Great underwater forests of kelp exist in many parts of the ocean. These forests provide shelter for numerous animals, including fish. Other animals, such as sea otters, roam the kelp forests in search of food.

much deeper. The deepest areas occur in trenches—long, narrow valleys on the sea floor. The deepest known spot is in the Mariana Trench in the western Pacific Ocean, near the island of Guam. It lies 35,840 feet (10,924 meters) below sea level. If the world's highest mountain, 29,035-foot (8,850-meter) Mount Everest, were placed in that spot, more than 1.3 miles (2.1 kilometers) of water would cover the mountaintop.

The Java Trench is the lowest point in the Indian Ocean. It lies 23,812 feet (7,258 meters) deep. The deepest point of the Atlantic lies in the Puerto Rico Trench at 28,232 feet (8,605 meters) below the surface. In the Southern Ocean, the deepest point exists 23,737 feet (7,235 meters) below sea level at the southern end of the South Sandwich Trench. The Arctic's deepest point lies in a deep plain north of the islands of Svalbard and

The world ocean

This map shows the world ocean, which includes the Atlantic, Indian, and Pacific oceans. It also shows the ocean's major surface currents.

measures 15,305 feet (4,665 meters) below sea level.

Temperature. The surface temperature of the ocean varies from about 28 °F (−2 °C) near the North and South poles to about 86 °F (30 °C) near the equator. In polar regions, surface seawater freezes. The western tropical Pacific has the warmest surface water. Ocean currents affect surface temperature. Some currents carry warm tropical water toward the poles. Other currents bring cold surface waters from the poles toward the equator.

Ocean temperature also varies with depth. In general, the temperature falls as the depth increases. The warm surface waters extend to depths of about 500 to 1,000 feet (150 to 300 meters). Below the surface waters, the temperature decreases rapidly, forming a layer called the *thermocline.* The thermocline varies in thickness, from about 1,000 to 3,000 feet (300 to 900 meters). From

the thermocline to the sea floor, the temperature decreases more slowly. Ocean temperature ranges between 34 and 39 °F (1 and 4 °C) near the bottom. In some regions, colder and deeper water rises to the surface, lowering the surface water temperature.

Composition. The ocean likely contains every natural chemical element. But the sea is best known for its salts. On average, the weight of seawater contains about 3.5 percent salts. Eleven *ions,* or molecules with electrical charges, account for the ocean's *salinity* (saltiness). They are, in order of concentration, chloride, sodium, sulfate, magnesium, calcium, potassium, bicarbonate, bromide, borate, strontium, and fluoride. The most abundant form of salt consists of the ions sodium and chloride.

Many ions in the ocean come from the dissolving of rocks on land. As rocks break down, rivers carry the resulting ions to the ocean. Volcanoes and undersea hot springs also contribute ions to the ocean. Evaporation and precipitation further affect ocean salinity. Evaporation removes fresh water from the ocean surface, leaving behind salts. Precipitation, however, returns fresh water to the ocean. Evaporation in subtropical areas is greater than precipitation, so these areas have especially salty surface waters. Closer to the equator, precipitation is greater than evaporation, making surface waters less salty there. Rivers also bring fresh water to the ocean, which lowers the salinity of seawater near river mouths.

The importance of the ocean

As a wealth of resources. The ocean provides many major resources. They include (1) food, (2) sources of energy, (3) sediments, and (4) medicines.

Food from the ocean consists mainly of fish and shellfish. Most of the catch comes from coastal waters. The world's fishing fleets harvest many kinds of fish and shellfish. The chief kinds include anchovies, cod, haddock, herring, lobsters, mackerel, oysters, sardines, shrimp, and tuna. The fishing industry also is developing new products and markets to make use of less familiar types of seafood. For example, *surimi,* a fish product developed in Japan, can be made into imitation crab, lobster, scallop, and shrimp. Processors use many fish not traditionally eaten, including certain species of flounder, to make protein powders with which to enrich foods.

Seaweeds also serve as a source of food, in addition to having industrial uses. *Kelp,* a large seaweed, is one of the most important. Kelp contains such nutrients as iodine and potassium. However, its chief value is as a source of *algin,* a thickening substance used in ice cream, salad dressing, cosmetics, and other products.

People farm the ocean much as they farm the land. In a type of farming called *aquaculture* or *mariculture,* farmers raise fish, shellfish, and seaweeds near ocean shores as well as in ponds. They use special methods to make the animals and seaweeds grow faster and larger than they would in the wild. Fish hatcheries produce healthy young salmon and other young fish for release into the ocean. See **Aquaculture**.

Sources of energy from the ocean have several forms. Petroleum and natural gas rank as the ocean's most valuable energy resources. Offshore wells tap deposits of oil and gas beneath the sea floor. Today, about 30 percent of worldwide oil and gas comes from offshore production. Scientists estimate that from 63 billion barrels to as much as 530 billion barrels of oil lie undiscovered beneath the ocean. One barrel equals 42 gallons (159 liters Equally huge amounts of untapped gas accompany the oil. As gas and oil reserves on land are used up or become too difficult and expensive to obtain, undersea deposits will become increasingly important. See **Gas** (Producing gas); **Petroleum** (Offshore drilling).

The ocean tides also provide energy. Tidal power facilities use the energy in the rise and fall of the tides to produce electric power. Unlike petroleum and gas, this source of energy is renewable. The first tidal power plant opened in 1966 on the Rance River near St.-Malo, France. Ocean waves also provide potential sources of renewable energy. See **Energy supply** (Tidal energy).

Sediments are materials deposited at the bottom of the ocean. Ocean sediments collect as sand, mud, minerals, and other materials. Important sediments recovered from the ocean include sand and gravel mined from the sea floor and used to make construction materials. People also use some sand to restore damaged beaches. Seawater itself contains such important minerals as bromide and magnesium. These minerals can be removed by letting seawater evaporate in large shallow basins under sunlight. The evaporation leaves the mineral deposits behind in the form of salts. The salts themselves and such elements as magnesium and bromide can be extracted from the deposits. Other methods to remove minerals from seawater include chemical and electrochemical processes.

The mineral wealth of the ocean extends to the deep-sea floor. The deep-sea floor contains vents from which hot water flows. Deposits at these *hot vents,* also called *hydrothermal vents,* contain copper, iron, and zinc. But mining the ores would prove expensive and difficult, and the techniques must still be developed. Manganese deposits lie on the ocean bottom in lumps called *nodules.* The nodules also contain valuable amounts of cobalt, copper, and nickel. Possible techniques to mine these nodules include using buckets that run on convey or belts between a ship and the sea floor, or operating device that works like a giant vacuum cleaner.

Medicines may be produced from many forms of marine life. For example, plantlike organisms called *red algae* could provide *anticoagulants,* drugs that keep blood from clotting. A family of marine snails produces substances that may treat pain. Sea life has also aided medical research. The blood of horseshoe crabs contains a substance used to test for infections and bacteria contamination. Researchers study nerve cells from lobsters, squids, and marine worms to learn more about how th human nervous system functions.

Other products from the ocean include coral, pearls, and shells used in jewelry. Many people believe that natural sponges from the ocean bottom are of higher quality than synthetic sponges. In many dry areas near seacoasts, people *desalinate* (remove the salt from) seawater to produce fresh water for drinking and industria uses (see **Water** [Fresh water from the sea]).

As an influence on climate. The ocean helps stabilize Earth's climate. The ocean's great size and the slowness of water to change temperature have a steadying influence on the temperature of the atmosphere. In summer, the ocean stores heat from the sun. In winter, when the sunlight is weaker, the ocean releases the

stored heat into the air. Currents carry the heat of tropical waters toward the poles, thereby cooling the tropics and warming the polar regions.

The ocean is the source of most precipitation that falls to the earth. The sun's heat evaporates water from the ocean surface. The water rises as invisible vapor and forms clouds as it cools. It then falls back to the earth as rain, sleet, hail, or snow.

As a vast highway. The ocean has been a highway for trade since people built the first ships thousands of years ago. Shipping ranks as an important use of the ocean in international trade. See **Ship; Transportation.**

Life in the ocean

An incredible variety of living things resides in the ocean. Marine life ranges in size from microscopic one-celled organisms to the blue whale, which may measure up to 100 feet (30 meters) long. In a process called *photosynthesis,* ocean plants and plantlike animals use sunlight, carbon dioxide, water, and nutrients to produce their own food and materials for growth. Sea animals eat these organisms and one another. Marine plants and plantlike organisms can live only in the sunlit surface waters of the ocean, which is called the *photic zone.* The photic zone extends only about 330 feet (100 meters) below the surface. Beyond that point, the light is insufficient to support organisms that rely on photosynthesis. Animals, however, live throughout the ocean, from the surface waters to the greatest depths.

Three basic categories of marine organisms inhabit the oceans. They are (1) the plankton, (2) the nekton, and (3) the benthos.

The plankton includes plantlike organisms and animals that drift with ocean currents. They have little ability to move through water on their own. Most of them are so small that they cannot be seen without a microscope. Plantlike organisms of the plankton are called *phytoplankton,* and they include such simple creatures as diatoms and other algae. Animals of the plankton are among the organisms known as *zooplankton.*

Phytoplankton consist of several kinds of plantlike organisms. Most have only one cell and float in the photic zone, where they obtain sunlight and nutrients for photosynthesis. Although the organisms generally drift about, some kinds have long, whiplike parts called *flagella* that enable them to swim. Phytoplankton serve as food for zooplankton and some larger marine animals.

The most numerous phytoplankton are diatoms and dinoflagellates. A diatom consists of one cell enclosed in a hard, glasslike shell made of silica. Diatoms live mainly in colder regions of the ocean. Some even live within sea ice. Most dinoflagellates also are one-celled organisms. They generally live in more tropical regions. A dinoflagellate has two flagella it can use to move in a swirling motion. Sudden increases in certain dinoflagellate populations are called *red tides,* from the reddish discoloration that millions of these cells create in the water. Some dinoflagellates produce powerful poisons. When such species become plentiful, they may create a red tide that kills many sea animals (see **Red tide**). Other kinds of phytoplankton include coccolithophores, one-celled organisms with a hard shell made of calcite; and silicoflagellates, which have a skeleton of hollow silica rods.

Zooplankton consist of many kinds of creatures, such as single-celled organisms and small animals that are unable to swim. They live at all depths in the ocean. Some planktonic animals float about freely throughout their lives. The rest spend only the early part of their lives as plankton. As adults, some become strong swimmers and join the nekton. Others settle to the sea floor or attach themselves to it and become part of the benthos. Crustaceans, a large group of *invertebrates* (animals without backbones), make up about 70 percent of all zooplankton. Tiny swimmers called copepods are the most numerous crustaceans. Shrimplike krill, another group of crustaceans, provide food for fish, sea birds, seals, squids, and whales.

The nekton consists of animals that can swim freely in the sea. They are strong swimmers and include fish, squids, and marine mammals. Most nektonic species live near the sea surface, where food is plentiful. But many other animals of the nekton live in the deep ocean.

Fish rank among the most important animals of the nekton. About 14,500 kinds of fish live in the ocean. The smallest fish, a goby with the scientific name *Trimmatom nanus,* lives in the Indian Ocean. It grows to about 0.4 inch (1 centimeter) long. The largest fish, the whale shark, measures as much as 40 feet (12 meters) long. Such fish as tuna and mackerel have streamlined bodies that enable them to swim rapidly through the water. Many fish of the deeper parts of the ocean have light-producing organs that may help attract prey. Such fish include deep-sea anglerfish and lanternfish.

Squids are free-swimming mollusks, a group of soft-bodied invertebrates, and have eight arms and two tentacles. Related animals include octopuses and cuttlefish. Squids live in surface and deep waters. They measure from less than 1 foot (0.3 meter) to as much as 60 feet (18 meters) long, including the tentacles. A squid moves backward through the water in a jetlike action by forcing water through a tube beneath its head.

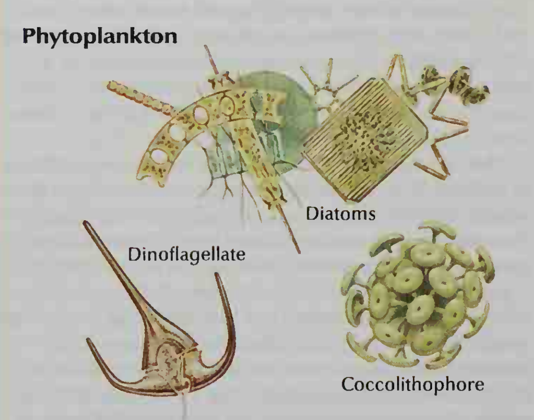
Nektonic mammals include dugongs, manatees, porpoises, and whales, all of which remain in the ocean for their entire lives. Other marine mammals, such as sea otters, seals, and walruses, also spend time on land.

The benthos is made up of marine organisms that live on or near the sea floor. Animals of the benthos may burrow in the ocean floor, attach themselves to the bottom, or crawl or swim about within the bottom waters. Where sunlight can reach the sea floor, the benthos supports plants and plantlike organisms, such as kelp and sea grass, which become anchored to the bottom. Common benthos animals include clams, crabs, lobsters, starfish, and various worms. Some fish have features specially suited for life on the sea floor. For example, halibut and sole, which lie sideways on the bottom, have both eyes on the side of the head facing up.

Most bottom-dwelling creatures are part of the plankton and drift with the currents during the early stages of their development. They then sink to the sea floor where, as adults, they become part of the benthos. Such animals include barnacles, clams, corals, oysters, and a variety of snails and worms.

The food cycle in many parts of the sea begins with the phytoplankton that produce food by photosynthesis. Certain zooplankton eat the phytoplankton. Those animals, in turn, become food for other zooplankton or for

Life in the ocean



The ocean contains a remarkable variety of life, from tiny microorganisms to gigantic whales. Different kinds of organisms inhabit different levels of depth in the ocean waters.

Plankton

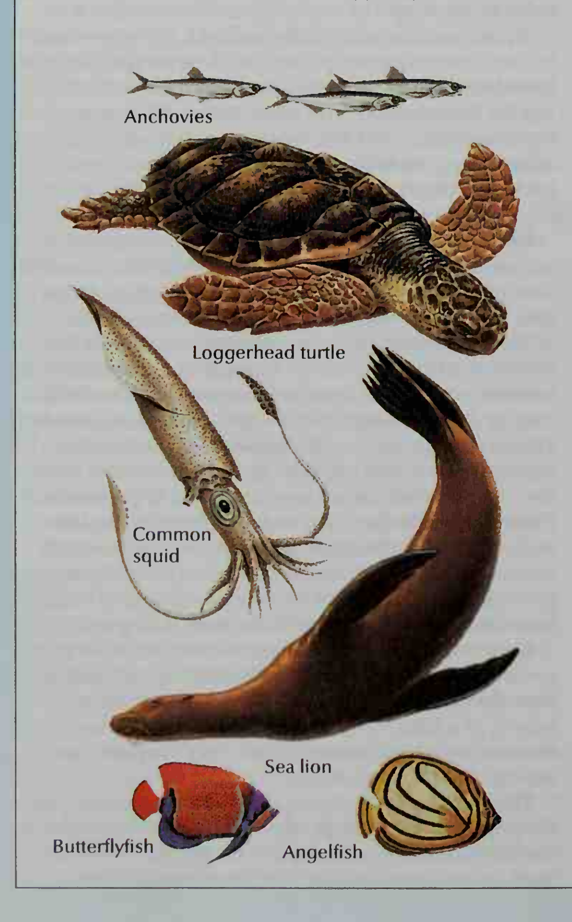
WORLD BOOK illustrations by Alex Ebell

Plankton consists mostly of small marine organisms that drift with ocean currents. The plantlike organisms are called *phytoplankton*. Planktonic animals are among the organisms known as *zooplankton*.

Phytoplankton

Zooplankton

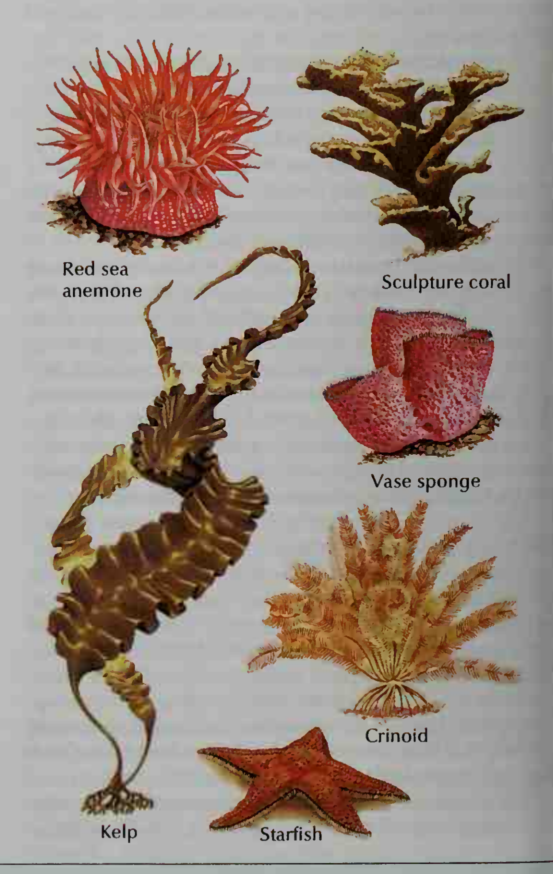
Crab larva



Barnacle larva

Copepod

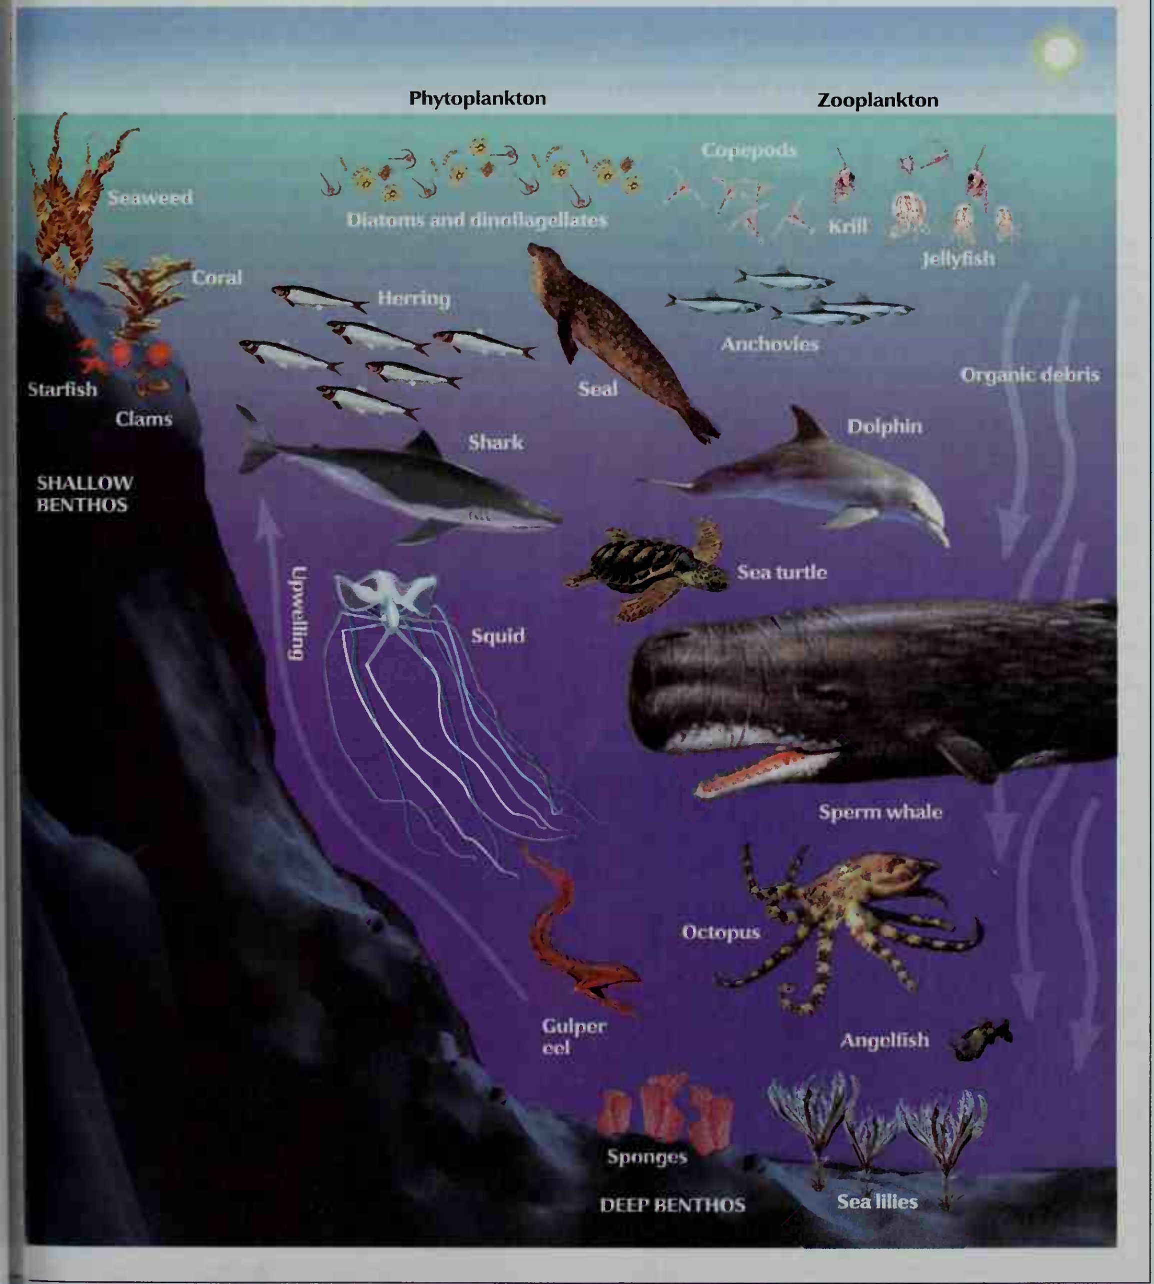
Hydromedusa



Nekton

Nekton is made up of fish and other animals that have the ability to swim freely in water without the help of currents. Most nektonic creatures live in the upper layer of the ocean.

Benthos



Benthos consists of marine organisms that live on the ocean bottom. Some members of the benthos are attached to the bottom in one position throughout their lives.

The ocean's cycle of life

The creatures of the ocean make up a complex web of life. For most marine life, the food cycle begins with tiny organisms called *plankton*. Plantlike *phytoplankton* use sunlight, carbon dioxide, water, and nutrients in the water to make food. *Zooplankton,* which are animals, eat phytoplankton or other zooplankton. These organisms, in turn, serve as food for fish, whales, and other animals that swim, called the *nekton*. Many larger creatures of the nekton eat smaller nektonic animals. Animals of the *benthos* (sea floor), such as sponges and sea lilies, depend on organic debris falling from the upper ocean. Finally, *upwellings* (deep waters that rise to the surface) carry waste products and other organic debris back to the surface, where they serve as nutrients for the phytoplankton.

WORLD BOOK illustrations by George Fryer, Bernard Thornton Artists

fish and other animals of the ocean.

After ocean organisms die, they begin to sink. Before most dead organisms sink far, they are eaten by creatures dwelling at lower depths. Dead organisms that are not eaten immediately begin to decompose. Bacteria and fungi cause the organisms to decompose by breaking them down into *nutrients* (nourishing chemicals). In addition, bacteria and fungi break down waste products given off by marine life. Rising currents carry the nutrients to the surface, where phytoplankton use them for photosynthesis, completing the food cycle.

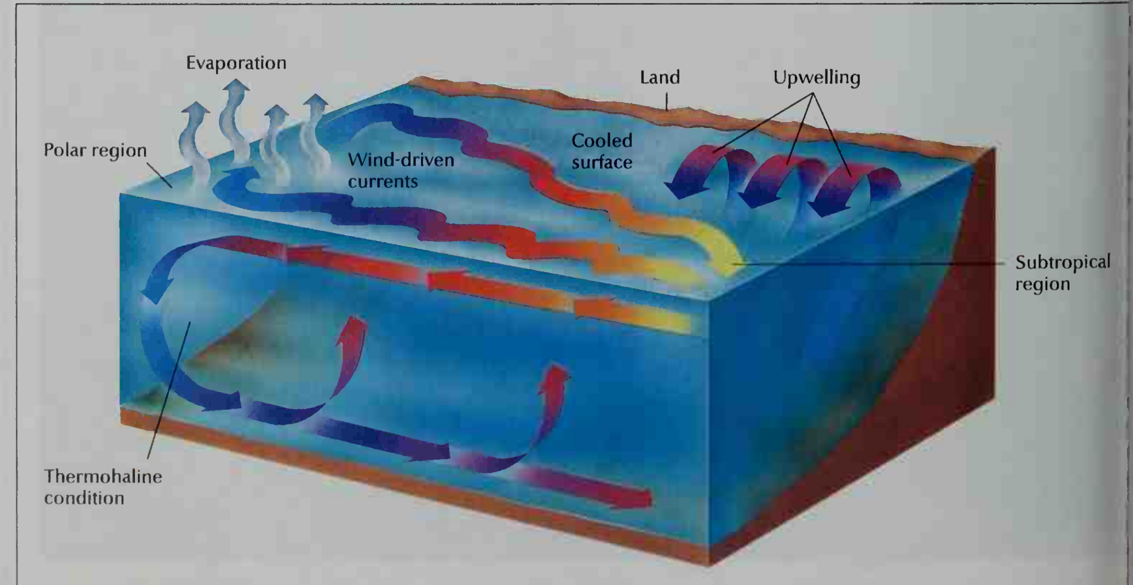
Hot vents support thriving communities of marine life. However, the food cycle at hot vents is not based on phytoplankton. Instead, such microscopic organisms as bacteria and *archaea* serve as the food base. Archaea are single-celled organisms that rank among the oldest forms of life on Earth. In a process called *chemosynthesis,* these microorganisms use energy from chemicals in the water instead of sunlight to produce food and grow. Other living things rely on archaea for food.

How the ocean moves

Ocean currents move through the sea like giant meandering rivers. Winds and earthquakes create waves across the surface of the ocean. The gravitational pull of the moon and sun causes movement, producing the daily rise and fall of the tides.

Circulation. Two main types of circulation exist in the ocean. They are (1) *wind-driven currents* and (2) *thermohaline circulation.*

Wind-driven currents result from wind blowing on the ocean surface. The wind sets surface waters into motion as currents. Currents generally flow horizontally—that is, parallel to Earth's surface. The wind mainly affects only the upper 330 to 660 feet (100 to 200 meters) o[f] water. However, the flow of wind-driven currents may extend to depths of 3,300 feet (1,000 meters) or more.



Wind-driven currents move in enormous circular patterns called *gyres.* Gyres flow clockwise in the subtropics of the Northern Hemisphere and counterclockwise in the subtropics of the Southern Hemisphere. Several conditions influence the direction of wind-driven currents and make them form gyres. Earth's wind systems drive the currents in an easterly or westerly direction. Continents direct the flow toward the north or south. Earth's rotation further causes the currents' circular paths. Major wind-driven currents include the North and South Equatorial currents, the California Current, the Canary Current, the Gulf Stream, the Kuroshio (Japan Current), the Labrador Current, and the Peru Current. The Antarctic Circumpolar Current is the strongest ocean current and the only one that circles Earth without hitting continents. See *The world ocean* map in this article for the location of the major currents.

In some areas, *upwelling* occurs when winds cause surface waters near the coast to move offshore. Colder, deeper waters, which are rich in nutrients, then rise to the surface near the coast. The upwelling of deeper waters provides nutrients for the growth of phytoplankton, which fish and other sea animals eat. Upwelling areas have great numbers of fish and, in fact, yield half of the world's fish catch. Important upwelling regions include the coasts of Peru and northwestern Africa, as well as along the equator and around Antarctica.

Thermohaline circulation produces great vertical movements of water that flow from the surface to the

Ocean currents result from two forces: (1) the action of the wind on surface waters, and (2) the differences in temperature and salt content of surface and deeper waters. The earth's general wind circulation produces the major currents—great streams that carry the ocean's surface waters in roughly circular patterns. Wind also causes *upwelling,* which occurs when coastal waters are blown offshore and replaced by colder, deeper waters. *Thermohaline circulation* takes place because colder, saltier water sinks. This action produces great vertical currents in the ocean.

WORLD BOOK illustration by Sarah Woodwa[rd]

The ocean as a conveyor belt

Thermohaline circulation produces a worldwide current comparable to a conveyor belt. Cold, dense waters descend from the surface in the North Atlantic and spread first to the Southern Ocean, then around Antarctica, and then into the Indian and Pacific oceans. In the North Pacific, the waters migrate upward as they become warmer and less saline. They then travel back to the Indian Ocean and through the southern Atlantic. The waters eventually reach the North Atlantic, where the conveyor belt begins again.

VORLD BOOK map

Colder subsurface waters

Warmer surface waters

ocean depths. The circulation results from differences in water temperature and salinity. In the polar regions, sur-ace waters are colder and saltier. Being colder and salti-er makes these waters heavier, and they sink toward the ocean bottom. They then gradually flow back toward the surface and replace the surface waters that sink.

Thermohaline circulation produces a worldwide cir-cuit comparable to a conveyor belt. Cold, dense waters descend from the surface in the North Atlantic and spread southward in deep areas of the ocean. Upon eaching the Southern Ocean, these waters sweep east-vard around Antarctica and then spread northward into he Indian and Pacific oceans. In the North Pacific, the vaters migrate upward as they become warmer and ess saline. They then follow the surface circulation, re-urning southward into the Indian Ocean and through he southern Atlantic around the Cape of Good Hope. hey eventually reach the North Atlantic, where the con-eyor belt begins another global circuit. Such waters ake about 1,000 years to make one complete circuit.

Waves. In addition to creating currents, wind pro-luces the up and down movements of an ocean wave. lo forward motion of water occurs as a wave goes nrough the water. The action of an ocean wave resem-les waves you can make in a rope that is tied to a tree. you shake the rope's free end, waves run along it. But ne rope itself does not move forward. When an ocean vave reaches land, however, it starts to drag on the bot-om. The wave becomes steeper and breaks, producing rush of water against the shore called *surf.* See **Waves.**

Ocean waves vary in size from small ripples to giant urricane waves more than 100 feet (30 meters) high. Vave size depends on wind speed, on how long the vind blows, and on how far it blows over the ocean. he waves continue to move over the ocean surface and an travel great distances from where they began. If the vind stops, the waves become smoother and longer. Vaves created by strong winds in the open ocean may ecome so steep that they break in a manner similar to urf. These breaking waves are called *whitecaps.*

The action of ocean waves changes the shoreline. Vaves cut away sloping land and leave steep cliffs. They reak up exposed rocks and form beaches. The move-ent of the waves and currents shapes beaches and builds up sand bars along the shore. Waves also carry beach sand away, particularly during storms.

Another type of wave results from sudden movements of the sea floor that are usually caused by earthquakes or underwater landslides. Scientists call such waves *tsunamis.* Some people call these waves *tidal waves,* though the tide does not cause them. On the surface of the open ocean, tsunamis can barely be seen. The waves typically measure about 3 feet (1 meter) high or less. But they can travel as fast as 600 miles (970 kilometers) per hour. As they approach a coast, they slow down and may pile up to a tremendous height, causing great damage along the coast. Most tsunamis strike land areas in or bordering the Pacific Ocean. Sometimes, scientists can predict when a tsunami may form and warn people in its path. See **Tsunami.**

Tides are the rhythmic rise and fall of ocean waters. In many coastal areas, water slowly rises along the shoreline for about six hours every day. Then it slowly falls back for about six hours. Tides are caused chiefly by the gravitational pull of the moon on Earth. The moon's gravity is strongest on the surface of Earth directly facing the moon. When ocean waters face the moon, the moon's gravity pulls the water up and forms a high tide in that area. The moon's gravity is weakest on the side of Earth opposite from the moon, enabling water there to move away from Earth as it rotates. This action produces another high tide bulge. As Earth rotates each day, high tide bulges move around the planet.

The sun's gravitational pull also affects the ocean. But the sun causes tides only about half as high as those caused by the moon. The gravitational pull of the moon and sun combine during the full moon and new moon. At such times, the sun, moon, and Earth are in a straight line. The tides then rise higher and fall lower than usual. They are called *spring tides.* When the moon is in its first and third quarters, the sun and moon are at right angles to each other with respect to Earth. The resulting tides do not rise or fall as much as usual. They are called *neap tides.* See **Tide.**

The land at the bottom of the sea

The ocean floor is a region of spectacular contrasts. Broad plains cover huge distances, towering mountain

The land beneath the oceans

The geography of the land beneath the oceans features long mountain ridges, broad basins, and deep trenches. This computer-generated map shows many of the major landforms of the ocean floor. Oceanographers created the map using information gathered from a variety of sources, including radar equipment from satellites and sonar devices on ships and in the sea. Deeper elevations on the map appear in darker colors, while shallower elevations appear in lighter colors. The map index below indicates the locations of individual sea floor features.

chains circle the planet, undersea volcanoes rise toward the surface, and trenches and valleys reach great depths.

The continental margin forms the part of the seabed that borders the continents. It consists of (1) the continental shelf, (2) the continental slope, and (3) the continental rise.

The continental shelf is the submerged land at the edge of the continents. It begins at the shoreline and

gently slopes underwater to a depth less than 660 feet (200 meters). The width of the continental shelf usually ranges between 19 and 190 miles (30 and 300 kilometers). In certain areas, such as parts of the Arctic Ocean, the shelf extends over 620 miles (1,000 kilometers). In other areas, particularly those bordering much of the Pacific, it measures only 1 mile (1.6 kilometers) or less. Valleys of varying depths cut through the shelf. Sediment carried into the ocean by rivers collects on the shelf.

The continental slope begins at the outer edge of the shelf. The slope is much steeper than the shelf and plunges to depths of 2.2 miles (3.6 kilometers). The slope forms the sides of continents. Its width ranges from 12 to 60 miles (20 to 100 kilometers). In many places, deep underwater canyons gash the slope. Some canyons rival the gigantic Grand Canyon of North America in size. Many underwater canyons lie offshore from large rivers, and sediment-laden waters may have carved them.

The continental rise consists of sediment from the continental shelf and slope that accumulates at the bottom of the slope. The thick sediment deposits of the continental rise extend up to about 600 miles (1,000 kilometers) from the slope.

Deep-sea peaks, valleys, and plains lie beyond the continental margin in the ocean basin. *Mid-ocean ridges* form a chief feature of the basin. The ridges consist of a chain of mountains that runs about 37,000 miles (60,000 kilometers) through the world ocean. Scientists discovered the mountain chain independently in each ocean basin and gave it different names, including Mid-Atlantic Ridge, East Pacific Rise, and Mid-Indian Ridge. Most mountains of the mid-ocean ridges stand about 5,000 feet (1,500 meters) above the sea floor. Some peaks rise above the surface and form islands, such as the Azores and Iceland in the Atlantic Ocean. Deep valleys often cut across the ridges, producing a rugged, fractured surface. Some mid-ocean ridges have valleys down through the center of them. Frequent volcanic eruptions and earthquakes occur along such valleys.

The sides of the mid-ocean ridges slope down to the *abyssal plains.* Accumulation of sediment buries most features of the ocean floor on the abyssal plains, which are flat as a result. The chief sources of deep-sea sediment are the land itself and marine life. The breaking down and wearing away of rock produces land sediment, which rivers carry to the ocean. Wind also carries dust from deserts and other regions to the ocean. In addition, volcanic eruptions spread large amounts of ash over the ocean. Marine life sediment consists mainly of tiny shells and the remains of dead planktonic organisms. When such biological matter makes up a major part of a sediment, scientists call it an *ooze* (see Ooze).

Other features of the deep-sea basin include the long, narrow trenches and underwater mountains called *seamounts.* Trenches form the deepest parts of the ocean. Volcanic eruptions produce seamounts. These mountains have steep sides and may rise thousands of feet or meters above the sea floor.

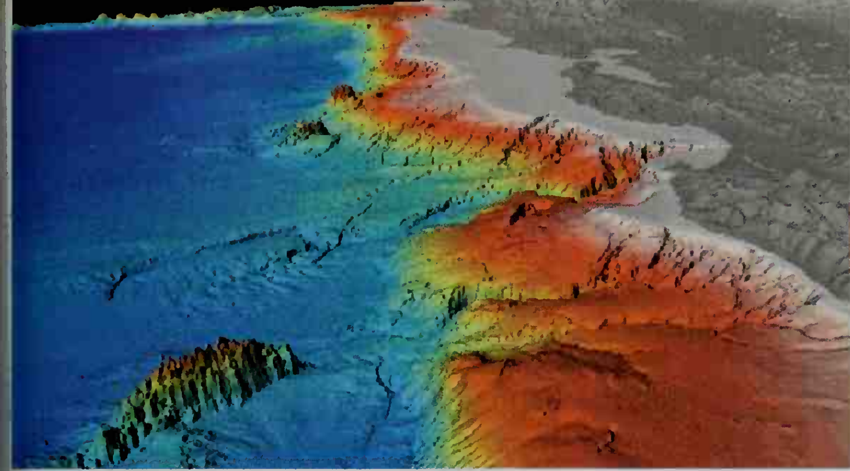
How the sea floor was formed. Since the late 1800's, scientists have developed several theories to explain how the sea floor was formed. The theory of *continental drift* first received wide attention during the early 1900's. According to this theory, the continents originally consisted of a single great land mass surrounded by one ocean. The land mass broke up into continents, which slowly drifted apart. New oceans, including the Atlantic and the Indian oceans, resulted from the drift of the continents.

At first, many scientists rejected the continental drift theory because no one could explain what forces might move continents. Then in the 1960's, a theory called *sea-floor spreading* provided some explanation. According to the theory, the sea floor itself moves, carrying the continents along. Circulating movements deep within Earth's *mantle*—that is, the partly molten layer of hot rock beneath the earth's crust—make the sea floor move. The circulating movements carry melted rock up to the mid-ocean ridges and force it into the central valleys of the ridges. As the melted rock cools and hardens, it forms new sea floor and pushes the old floor and the continents away from the ridges.

A theory called *plate tectonics* combines and expands on the ideas of sea-floor spreading and continental drift. According to plate tectonics, Earth's outer shell consists of huge rigid plates that move continuously. As the plates move, they carry the ocean floor and the continents with them. The relative movement of two neighboring plates is generally about 0.5 to 4 inches (1 to 10 centimeters) a year. Sea-floor spreading—and the formation of new sea floor—occurs where plates move apart. The mid-ocean ridges mark such areas.

As plates move away from one another in one place, they must move toward one another elsewhere. When two plates collide, one may pile up against the other, forming mountains. Or one plate may be drawn down into the mantle under the other plate. Such action produces trenches and volcanoes. Earthquakes occur at or near plate boundaries, where plates spread apart, collide, or slide past each other. The Atlantic Ocean is slowly growing wider, and the Pacific smaller, because of plate tectonics. See **Earth** (Earth's plates); **Plate tectonics.**

The oceanic crust forms the ocean floor. It consists of hard rock called *basalt.* The continents lie on the continental crust, which consists mainly of granite. Granite is lighter than basalt, and so the continental crust basically "floats" on the mantle, above the oceanic crust. Ocean basins, as sunken areas, thus collect water. Most scientists believe that the water now filling the oceans came from a number of asteroids and comets that struck Earth as it formed nearly 4.6 billion years ago. Much of it was released from rocks within Earth by volcanic activity.



Exploring the ocean

By exploring and understanding the ocean, we can learn to manage its resources wisely.

Tools of exploration. The tools that oceanographers use in their efforts to explore the sea include (1) research ships, (2) research submarines called *submersibles,* (3) satellites, and (4) computers.

Research ships typically measure about 100 to 300 feet (30 to 90 meters) long and include laboratory space where scientists can work while at sea. Oceanographers use research vessels to make measurements, perform experiments, and study marine processes. They may stay at sea for weeks or months at a time. They often work in rough seas and in distant locations around the world.

Oceanographers use several types of instruments on research ships. They operate underwater cameras to

© William Haxby, Lamont-Doherty Earth Observatory/Columbia University

Computer-generated images provide information about water temperatures in the ocean and about the ocean's geological history. In this view of coastal California, light gray, red, and orange colors represent the shallowest, warmest waters. Blue and purple indicate the deepest, coldest waters. The picture also shows how erosion has shaped the sea floor, creating canyons and other features.

photograph the sea floor. Electronic devices measure the depth of the sea by sending out sound waves and recording their echoes from the ocean floor. The most powerful of such instruments detect echoes from deep within Earth's crust. Scientists analyze the records to learn about the structure of the crust. Oceanographers also measure temperature, salinity, and a wide array of chemicals in the ocean. Nets towed behind research ships gather samples of marine life for study.

Oceanographers also use a number of floating devices. For example, a *mooring* consists of an anchor and a float connected by a cable. The float may be placed at the sea surface or at a specific depth. Scientists attach various instruments to the cable of a mooring. Some instruments measure the speed and direction of ocean currents at different depths. Other devices record the emperature and salinity of the water. A mooring may emain at sea several years before the research ship picks up the device and the data it has collected.

Other floating devices include *buoys,* which drift with he ocean's surface currents. Buoys chiefly provide information about ocean circulation. But they may also ecord air pressure or surface water temperature. Buoys elay data to scientists through orbiting satellites. Some uoys can drift with currents below the ocean surface.

Oceanographers use specialized equipment to collect amples from the ocean bottom. Scientists can gather ock samples from the mid-ocean ridge by towing a dredge along the sea floor. Other ships can drop long, heavy pipes into the sea floor to collect vertical samples of sediments called *cores.* Because sediments are deposited in layers over time, studies of cores can determine how old the sediments are. The age and composion of the sediments can reveal how oceans have hanged over time. See **Ocean Drilling Program.**

Submersibles can descend to the depths of the cean. They enable scientists to observe features on the ea floor that may be missed by instruments lowered om research ships on the surface.

Piloted submersibles, such as the U.S. *Alvin,* carry a uman crew. The crew members take photographs and se a mechanical arm outside the vessel to gather samles and set out instruments.

Other submersibles, called *remotely operated vehies* (ROV's) or *autonomous underwater vehicles* (AUV's), arry no crew. ROV's usually are controlled from a ship y a cable. They have television cameras and sensors at can return information about the sea floor environent. In 1985, two remotely operated submersibles—the U.S. *Argo* and the French *Sar*—found and explored the wreckage of the *Titanic,* a British passenger ship that sank in the Atlantic in 1912. AUV's are self-contained vehicles controlled by an onboard computer programmed with instructions. They can explore specific areas of the ocean, take measurements, and collect samples. AUV's return to the control ship or station to recharge batteries, return data and samples, and receive new instructions in their computers. See **Diving, Underwater.**

Satellites transmit data from buoys and other instruments at sea to oceanographers on shore. They also provide views of vast expanses of the sea from their position high above Earth. In general, satellites supply information more quickly over a larger area than do research ships.

Satellite images can show the distribution of sea ice, the extent of surface oil slicks, and the cloud formations over the ocean. Satellites can help map the temperature and color of the ocean surface. Some satellites can even detect the small differences in the elevation of the sea surface caused by ocean currents. Such data help oceanographers in many ways. For example, scientists can study variations in the routes and patterns of ocean currents and their effects on climate and weather. Researchers can also determine biological activity in the ocean's surface waters, as well as understand how the

Woods Hole Oceanographic Institution

The submersible *Alvin* can carry a crew of scientists to the ocean floor, where they take photographs and gather samples.

ocean affects weather and climate.

Computers enable oceanographers to collect and analyze the enormous amounts of data obtained every day from satellites, from instruments on research ships, and from buoys. Scientists also use computers to create *models* (mathematical representations) of the ocean's movement and structure. The models enable them to understand and predict the ocean's behavior and its effect on the environment.

Discoveries. Oceanographers constantly make new and interesting discoveries about the sea. One of the exciting discoveries occurred in 1977, when scientists first detected a hot vent on the sea floor near the Galapagos Islands in the eastern Pacific Ocean. Similar vents have been found elsewhere in the eastern Pacific and along portions of the Mid-Atlantic Ridge. Hot vents occur at depths of about 8,200 to 10,000 feet (2,500 to 3,000 meters) on the mid-ocean ridges, where new sea floor forms as the tectonic plates move apart.

Hot seawater containing such chemicals as copper, iron, manganese, zinc, and sulfate flows from the vents. As the hot water mixes with colder seawater containing oxygen, chemical reactions form dark-colored mineral particles. These particles produce deposits around the vents. The deposits take the shape of "chimneys" through which the water shoots out. The dark-colored minerals make the water look like black smoke, and so these hot vents are called *black smokers.*

Communities of strange marine life live at hot vents. Scientists discovered that some kinds of bacteria and archaea that live there use chemosynthesis to produce food. Such organisms serve as the base of the food chain for the vent communities. Scientists previously thought that all food chains throughout the ocean began with the energy from sunlight and the photosynthesis that takes place in shallow waters. Other forms of life found near hot vents include clams up to 1 foot (30 centimeters) long and giant tubeworms measuring up to 10 feet (3 meters) long. Scientists have also discovered various species of crabs, fish, shrimp, and other animals in the vent communities. Most of the animals were previously unknown species of marine life.

Oceanographers often make discoveries as they apply new instruments and techniques to study the ocean. The use of specialized research ships, satellites, and computers has increased their knowledge of oceanic processes. For example, such technology has enabled us to better understand the effects of *El Niño* in Earth's weather and climate systems. El Niño is an interaction between the atmosphere and the waters of the Pacific Ocean that occurs about every two to seven years. During an El Niño, a warm current flows southward along the west coast of South America, warming the normally cold coastal waters of Ecuador and Peru. The warming of the ocean waters kills many fish and the sea birds that rely on fish for food. A typical El Niño lasts about 18 months.

For years, El Niño was considered only a local phenomenon. In the 1960's, however, scientists observed a connection between El Niño and a change in the normal trade winds over the tropical Pacific Ocean. In the 1990's, oceanographers used a variety of ships, satellites, and electronic instruments to study the ways in which the tropical ocean and atmosphere interact to produce El Niño events. They discovered that El Niño and an opposite pattern called *La Niña* that often follows are part of a larger atmospheric pattern known as the *Southern Oscillation.* El Niño studies have also enabled scientists to predict El Niño events—and their effects—from 6 to 18 months in advance. These effects include rainfall and drought conditions, as well as severe forest fires and floods. See **El Niño.**

International cooperation. Increasingly, many countries now cooperate with one another in conducting scientific studies of the ocean. Major international investigations have studied such issues as the circulation of ocean waters, the changes in the sea's chemical content, and the structure of marine ecosystems. In addition, efforts are underway to develop a global ocean observing system to better understand natural and human-induced changes in the marine environment.

Ocean problems

For thousands of years, people used the ocean and its vast resources with little concern for their conservation. But during the last two centuries, increases in human population, industrial development, and use of coastal regions has put the health of the sea at risk, forcing people to address ocean conservation problems. Many of the major problems involve marine pollution, depletion of fisheries, habitat modification, and climate change.

Marine pollution. *Pollutants* (substances that cause pollution) enter oceans through accidents, carelessness, and the deliberate disposal of wastes. The ocean can absorb some types of pollutants in certain quantities because of its great size and the natural chemical processes that occur within it. But the ocean's capacity to absorb and recycle pollutants can become overwhelmed.

People pollute the oceans in several ways. Major ocean pollutants include waste products, which people often dump deliberately into the ocean, and oil, which usually enters the sea by accident.

Waste products that enter the ocean include sewage, plastic litter, and industrial wastes. Sewage, such as human waste and ground-up garbage, often fouls coastal regions. This kind of waste contains organic matter that decomposes and reduces the levels of oxygen in the water. Low oxygen levels make the water unfit for animals. Sewage also contains nitrates, phosphates, and other nutrients that stimulate the growth of phytoplankton. An overabundance of certain phytoplankton produces a condition called *eutrophication,* which also reduces the water's oxygen levels. Rapid growth of some phytoplankton can create *red tides.* Red tide phytoplankton produce toxins that poison marine life.

Plastic litter can severely damage the ocean because it does not break down easily. Sea birds, turtles, seals, whales, and other marine animals can get tangled in plastic nets, bags, and packing material. These animals may also mistake plastic items for food and die of starvation if the plastic blocks their digestive system. In addition, plastics and other litter make the marine environment less attractive. Many countries ban the disposal of plastics into the ocean, but such litter remains a common problem on shorelines.

The deliberate dumping of industrial waste into the sea from ships and barges has also polluted oceans. Such wastes have included ash from power plants, contaminated sediments dredged from harbors, and even

radioactive wastes. Since the 1970's, many countries have begun banning ocean dumping of most wastes. But the disposal of some types of wastes, such as dredged sediments, may likely continue.

Oil pollution enters the ocean from oil spills on land or in rivers. Oil also seeps into the ocean naturally from cracks in the sea floor. Oil tanker and oil well accidents at sea account for only a small portion of ocean oil pollution, but their effects may be disastrous. The world's largest accidental oil spill occurred in June 1979, when an oil well blew out off the east coast of Mexico and spilled about 140 million gallons (530 million liters) of oil. The world's largest oil spill occurred when Iraq deliberately released between 240 million and 465 million gallons (910 million and 1,760 million liters) of oil into the Persian Gulf during the Persian Gulf War (1991). In water, much of the oil forms tarlike lumps, which foul beaches and other coastal areas. Oil also coats fish, birds, and mammals and kills many of them.

Fisheries. Since the latter part of the 1900's, the world's fishing industry has harvested fish from many ocean fisheries faster than the fish stocks can renew themselves. Some fishing techniques have proved especially destructive. These techniques include the use of dynamite and cyanide to stun or kill fish on coral reefs. They also include the use of nets that capture, injure, or kill species other than the ones being sought. In some cases, the depletion of commercially valuable fish species can alter marine ecosystems by making less valuable species more abundant. Such problems have led many countries to enforce limits on catch and even temporarily close a number of valuable fisheries.

Habitat modification. People have harmed marine ecosystems in many coastal regions by destroying such vital habitats as marshes; mangrove swamps, where the spreading roots of mangrove trees catch and hold silt from the water; and tidal flats, which are covered and uncovered twice daily by the tides. These environments often play an essential role in maintaining a healthy marine ecosystem. As a result, conservationists are attempting to stop further damage to such habitats and, in some cases, to restore the habitats to their natural state.

Climate change. Natural processes cause most kinds of climate change. But increasing evidence indicates that human activities can also produce changes in climate. Over the past 150 years, the combustion of such *fossil fuels* as petroleum, coal, and natural gas has increased the amount of carbon dioxide gas in the atmosphere by about 30 percent. Carbon dioxide traps heat from the sun in a process called the *greenhouse effect.* Increases in atmospheric carbon dioxide may enhance the greenhouse effect and significantly raise temperatures on Earth. Such changes in climate could greatly affect all marine ecosystems. See **Greenhouse effect**.

Scientists are working to determine the role of the ocean in climate, as well as the effects of human activities on climate change. Scientists have studied the possibility of disposing of carbon dioxide into the depths of the ocean as a way to keep Earth from overheating.

Who owns the ocean? This question has become more important as countries have learned that fish and other ocean resources can be used up and that valuable minerals and sources of energy lie on and under the sea floor. The United Nations has worked to develop an agreement on ownership of the sea. Its efforts resulted in the Law of the Sea Convention, drafted in 1982. This treaty went into effect in 1994, after more than 60 nations ratified it. The treaty provides for a system to protect the economic and environmental interests of coastal nations, while allowing the free passage of other countries' ships.

Under the Law of the Sea Convention, the laws of a coastal nation apply throughout its territorial sea, which extends 12 nautical miles (22 kilometers) from the na-

Marine geologists study features of the ocean bottom. These scientists are examining and describing vertical samples of sediment called *cores.* Cores are drilled from beneath the sea floor.

tion's shoreline. An *exclusive economic zone* (EEZ) extends, in most cases, 200 nautical miles (370 kilometers) beyond the nation's territorial sea. Each coastal nation, even if it is an island, has total control over resources and research within its EEZ. The remaining ocean area is defined as the *high seas,* where no nation may make a territorial claim. However, even on the high seas, various international agreements govern fishing methods and fishing catches, as well as disposal of wastes.

The United States has not signed the Law of the Sea Convention. At the time this treaty was drafted, the U.S. government believed the treaty did not adequately protect private industries involved in deep-sea mining operations. However, the United States is working to resolve this difference, and it supports exclusive economic zones and many other provisions of the treaty.

Careers in oceanography

The ocean can be studied in many ways, and the science of oceanography includes several specialties. *Physical oceanographers* study waves, tides, currents, and the action of the ocean and the atmosphere on each other. *Chemical oceanographers* study the chemical reactions that occur in the ocean. *Marine geologists* and *marine geophysicists* analyze the form and composition of the sea floor, as well as the forces that shape the ocean floor. Marine geologists mainly study the sediments and surface features of the ocean bottom. Marine geophysicists deal with the deeper oceanic crust. *Biological oceanographers* and *marine biologists* study marine life, from microscopic bacteria to large marine mammals. *Ocean engineers* design instruments to study the ocean, develop methods for obtaining minerals and other resources from the sea, and design structures for use in the ocean and on the sea floor.

To become an oceanographer, one needs a background in science and mathematics. Solid knowledge of at least one basic science, such as biology, chemistry, or geology, is required. Most oceanographers acquire detailed knowledge of oceans through graduate training.

An oceanographer may choose from several types of careers after completing training. Research jobs are available at colleges and universities, at oceanographic institutions, in government, and in industry laboratories. Colleges and universities also provide teaching jobs. Some oceanographers go on long research expeditions or make deep-sea dives. Others formulate theories or interpret scientific observations. Oceanographers may also work with computers in an attempt to re-create, analyze, and predict ocean behavior.

A deep-sea drilling ship uses propellers to stay in place despite wind and waves. Devices called *hydrophones* help maintain its position. They receive signals from a sonar beacon on the sea floor.

A drill string of pipe can be put back into a drill hole after removal for repairs. A remote television camera helps researchers guide the pipe to a reentry cone above the hole.

WORLD BOOK diagrams by Amie Zorn, Artisan-Chicago

Ocean Drilling Program is a scientific program that provides data on the composition of the Earth beneath the ocean floor. This information helps scientists understand the processes that have shaped the Earth. The program also provides information on the evolution of prehistoric life, the development of ice ages, and changes in the Earth's climate during the past 200 million years. Geologists use this information to learn how minerals form and where fossil fuels lie beneath the ocean.

The Ocean Drilling Program operates a special research drillship called the *JOIDES Resolution.* Teams of scientists from many nations participate on cruises that last about two months. During an expedition, the scientists remove cylindrical *cores* (samples) of sediment and hard rock from beneath the ocean floor. A drill pipe passes through a hole in the ship and extends beneath the sea floor. Within the pipe is a core barrel that brings up cores. Each core measures about 31 feet (9.4 meters) long and 2 ½ inches (6.4 centimeters) wide.

Many of the cores contain fossils and minerals that have accumulated over thousands or even millions of years. Scientists study them in a laboratory on board the ship to determine the age of the ocean floor and how it developed. Scientists can remove cores in water more than 27,000 feet (8,200 meters) deep.

The Ocean Drilling Program has continued the research begun by the Deep Sea Drilling Project. That project operated the drillship *Glomar Challenger* from 1968 to 1983. Among its many achievements, the Deep Sea Drilling Project confirmed the idea that the sea floor has spread away from underwater mountain ranges known as *mid-ocean ridges* as new sea floor has formed. Scientists believe that a giant land mass once united all the continents. Approximately 200 million years ago, the continents broke apart at the ocean ridges and gradually moved to their present positions.

Texas A&M University in College Station, Texas, operates the Ocean Drilling Program. The program receives funding from the United States National Science Foundation; from Australia, Canada, China, Japan, and South Korea; and from France, Germany, the United Kingdom, and 11 other countries in the European Science Foundation. Ocelot, *OH suh laht,* is a medium-sized animal of the cat family. It is known as the *leopard cat* or *tiger cat* of America. It is 3 ½ to 4 feet (107 to 120 centimeters) long including the tail, which is 15 inches (38 centimeters) long. The ocelot stands 16 to 18 inches (41 to 46 centimeters) high at the shoulder.

The ocelot lives in an area ranging from southeastern Arizona and southern Texas to Paraguay in South America. It spends most of its life on the ground, but it often hunts in forest trees and is an agile climber. It eats mice, wood rats, rabbits, snakes, lizards, birds, young deer, and monkeys. In the tropics, a favorite food is agoutis. If captured young, the ocelot can be tamed and makes an excellent pet.

The ground tint of ocelot fur varies greatly in different animals, ranging from reddish-yellow to smoky-pearl. Black spots vary in size from dots on the legs and the feet to large shell-shaped spots on other parts of the body. The ocelot has a pink nose and large, translucent eyes.

Ocelots have been widely hunted for their fur, and their number has decreased sharply. Laws that prohibit

Z. Leszczynski, Animals Animals

Ocher, *OH kuhr,* also spelled *ochre,* is a yellow to brownish-red type of earth. It is used to color inks, paints, and other substances. Heating the yellow variety produces burnt ocher, which has a rich red color. Ocher consists of iron oxide, clay, and sand. The state of Georgia has large ocher deposits. George J. Danker

Ochs, *ahks,* **Adolph Simon** (1858-1935), rose from a job as a newsboy to become the publisher and guiding influence of *The New York Times.* He separated editorial comment from news in the *Times* and presented news free from prejudice. In 38 years, the daily circulation of the *Times* rose from 9,000 to 460,000. Ochs also founded the magazine *Current History,* and gave $500,000 toward publication of the *Dictionary of American Biography.*

Ochs began his career at 14 as an errand boy at the *Knoxville* (Tennessee) *Chronicle.* Later, he bought a half-interest in the *Chattanooga Times,* and made it one of the area's strongest papers. He became manager of *The New York Times* in 1896, and gained controlling interest in 1900. He was born on March 12, 1858, in Cincinnati, Ohio. William McKeen

Ockham, William of. See William of Ockham.

Ocmulgee National Monument, *ohk MUHL gee,* is in central Georgia. It contains the most important prehistoric Indian mounds in the Southeast, including a restored council chamber. Ruins dating from 8000 B.C. were found there. The monument was established in 1934. For area, see National Park System (table: National monuments). Critically reviewed by the National Park Service

O'Connell, Daniel (1775-1847), an Irish statesman, helped lead the struggle of Roman Catholics to gain political rights in the United Kingdom. This struggle resulted in the passing of the Catholic Emancipation Act of 1829. That act gave Catholic men the right to serve in the British Parliament and to hold most other public offices. Previously, Catholics were denied these rights in the primarily Protestant United Kingdom. The new law had a major effect in Ireland, then a part of the United Kingdom where most of the people were Catholics. O'Connell, called "the Liberator," became the first Irish Catholic to win election to the British House of Commons. He served there from 1829 to 1847.

O'Connell was born on Aug. 6, 1775, in Cahirciveen, County Kerry. He became a lawyer in 1798. He formed the Catholic Association in 1823 to seek the political rights of Catholics. In Parliament, he played a key role in the passing of the Reform Act of 1832, which gave most middle class men the right to vote. He was arrested in 1843 for supporting a campaign demanding Ireland's complete independence from the United Kingdom. In 1844, he was convicted of plotting against the government and spent 14 weeks in jail. Thomas E. Hachey

O'Connor, Flannery (1925-1964), was an American author whose novels and stories are filled with characters who are physically deformed or emotionally or spiritually disturbed. Some are obsessed with religion and the possibility of their own damnation or salvation. But O'Connor's books also contain humor, irony, and satire.

Mary Flannery O'Connor was born on March 25, 1925, in Savannah, Georgia. Her Southern heritage and her Roman Catholicism strongly influenced her writing. She suffered from poor health most of her life and could complete only a few works. They include two novels, *Wise Blood* (1952) and *The Violent Bear It Away* (1960). Her stories were collected in *A Good Man Is Hard to Find* (1955) and *Everything That Rises Must Converge,* published in 1965 after her death. The stories in these two collections are included in *Flannery O'Connor: The Complete Stories,* published in 1971. This collection won the 1972 National Book Award for fiction. *Mystery and Manners,* essays and lectures on literature and writing, was published in 1969. A collection of her letters called *The Habit of Being* was published in 1979. Noel Polk

O'Connor, John Joseph Cardinal (1920-2000), was appointed a cardinal of the Roman Catholic Church by Pope John Paul II in 1985. The pope had named O'Connor archbishop of New York City in 1984. O'Connor received this appointment less than a year after becoming bishop of the diocese of Scranton, Pennsylvania.

O'Connor was born on Jan. 15, 1920, in Philadelphia. He was ordained a priest in 1945. O'Connor taught high school classes for seven years. He then joined the United States Navy and Marine Corps as a chaplain. In 1975, he was appointed Navy chief of chaplains. In 1979, he became an auxiliary bishop of the Military Ordinariate, a diocese that serves members of the U.S. armed forces. O'Connor served on a committee of bishops that drafted a pastoral letter condemning the nuclear arms race. The letter was approved by the National Conference of Catholic Bishops in 1983. Kenneth Guentert

O'Connor, Sandra Day (1930-), became the first woman to serve on the Supreme Court of the United States when she became an associate justice of the court in 1981. President Ronald Reagan appointed her to the court to fill the vacancy created that year by the retirement of Justice Potter Stewart.

As an associate justice, O'Connor has generally sided with conservative Supreme Court members. But she

has been sympathetic to liberal views on a small number of issues.

O'Connor was born in El Paso, Texas. She received a law degree from Stanford University in 1952. In 1965, she became an assistant attorney general of Arizona. In 1969, she was appointed to an unexpired term in the Arizona Senate. She won election to the state Senate in 1970, was reelected in 1972, and was Senate majority leader in 1973. O'Connor was elected a judge of a Maricopa County trial court in 1974. In 1979, the governor appointed her to the Arizona Court of Appeals, the second highest court in the state.

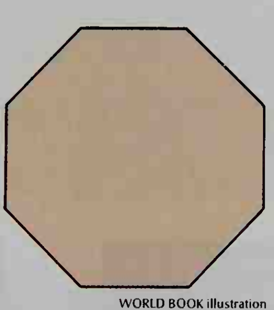
Ocotillo, *OH kuh TEEL yoh,* is a shrub that grows in the deserts of Mexico and Southwestern United States. It is also called *candlewood, coachwhip,* and *vine cactus.*

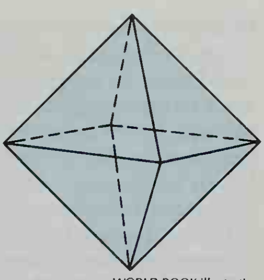
The ocotillo plant stands 6 to 25 feet (1.8 to 7.6 meters) tall, and has many long, spiny stems growing out from its base. After moderate to heavy rains, the stems bear leaves and bunches of scarlet flowers. But in the dry season, they stand bare as dry spiny sticks. Ocotillos make good hedges that are hard to pass through.



Scientific classification. Ocotillo is in the fouquieria family, Fouquieriaceae. It is *F. splendens.* Philip W. Rundel

WORLD BOOK illustration by Lorraine Epstein

Ocotillo looks like a bunch of dry sticks thrust into the sand in dry periods. After a heavy rain, tiny green leaves cover the plant's stems, and brilliant red blossoms form at the tips.



Octagon is a plane figure with eight sides. It is a type of polygon. The sides of an octagon meet at points called *vertices* to form eight interior angles. The interior angles of an octagon always add up to 1080°. A type of octagon called a *regular octagon* has equal sides and equal angles. The area of a regular octagon equals one-half the product of the perimeter and the *apothem,* the distance from the center of a regular polygon to the midpoint of one of its sides. Arthur F. Coxford, Jr.

WORLD BOOK illustration

A regular octagon, *above,* has eight equal sides.

Octahedron is any solid figure with eight faces. It is a type of *polyhedron* (solid figure with many faces). The faces of an octahedron need not have the same shape. Some may be triangles and others another kind of polygon. A variety of octahedron called a *regular octahedron* is a convex polyhedron in which all of the eight faces are congruent to any given equilateral triangle. John K. Beem

WORLD BOOK illustration

A regular octahedron, *above,* has eight faces, each of which is congruent to any given equilateral triangle.

Octane, *AHK tayn,* is any of 18 chemical compounds that consist of 8 carbon atoms and 18 hydrogen atoms. Octanes are among the main ingredients of gasolines. An octane called *isooctane* is used in a test mixture to determine how well a gasoline resists knocking (see **Octane number**). Gasolines that have a high octane number can prevent engine knock better than those with a lower octane number.

Octanes belong to a group of chemicals called *hydrocarbons* (see **Hydrocarbon**). All octanes are colorless liquids, all are highly flammable, and all have the same molecular formula, C_8H_{18}. However, they have different molecular structures and therefore different chemical and physical properties. For example, *normal octane,* also called *n-octane,* boils at 258.2° F. (125.7° C), but isooctane boils at 210.6° F. (99.2° C). Geoffrey E. Dolbear

Octane number, *AHK tayn,* is a number that tells how well a motor fuel resists "knocking." "Knocking" occurs when the last of the fuel in an engine cylinder burns too soon or too fast. The octane number of a motor fuel is found by comparing the fuel's knocking tendency with that of *reference fuels* in a test engine. Each reference fuel is a blend of *normal heptane* (a knock-prone fuel) and *isooctane* (a knock-resistant fuel). Normal heptane has an octane number of zero, and isooctane a value of 100. A motor fuel has an octane number of 85 if it produces the same knock as a reference fuel made of 85 per cent isooctane and 15 per cent normal heptane. Most gasolines have octane numbers from 80 to 100. See also **Gasoline.** Kathleen C. Taylor

Octave, in music. See **Music** (Musical terms).

Octavia, *ahk TAY vee uh* (69?-11 B.C.), was the older half-sister of the Roman ruler Octavian, who became the emperor Augustus in 27 B.C. Octavia married Octavian's co-ruler Mark Antony in 40 B.C. The marriage sealed a peace pact that ended a civil war between Octavian and Antony. Octavia bore Antony two daughters, Antonia the Elder and Antonia the Younger.

Antony treated Octavia badly. He had fallen in love with Cleopatra, queen of Egypt, before he married Octavia. In 37 B.C., Antony left Octavia to live with Cleopatra. He divorced Octavia in 32 B.C. Afterward, Octavia raised Antony's children by his first wife, Fulvia, in addition to her own children by Antony and her first husband, Marcellus. Octavia also raised Antony's children by Cleopatra after Antony and Cleopatra died in 30 B.C.

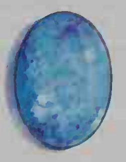
Judith P. Hallett

See also **Antony, Mark; Augustus; Cleopatra.**

Octavian. See **Augustus.**

Octillion, *ahk TIHL yuhn.* In France and the United States, an octillion is 1 followed by 27 zeros. In the United Kingdom, it is 1 with 48 zeros. See also **Decimal system** (The decimal system and number words).

October is the 10th month of the year, according to the Gregorian calendar, which is used in most parts of the world today. Its name comes from the Latin word for *eight.* October was the eighth month of the early Roman calendar. It later became the 10th month when the ancient Romans moved the beginning of the year from March 1 to January 1. October has had 31 days since the time of the Roman emperor Augustus.



Various kinds of holidays occur in this month. South Koreans celebrate National Foundation Day on October 3. This holiday marks the establishment of the kingdom of Choson in 2333 B.C. According to legend, Tangun, a son of a heavenly being, founded *Choson,* meaning *land of morning calm,* in present-day North Korea. Chulalongkorn Day falls on October 23 in Thailand. This national holiday honors King Chulalongkorn, also known as Rama V, who abolished slavery and introduced many reforms. New Zealand observes Labour Day on the fourth Monday in October.

The second Monday in October is Thanksgiving Day in Canada. Columbus Day in the United States also occurs on this day. It marks the arrival of Christopher Columbus in America on Oct. 12, 1492. The week including October 9 is Fire Prevention Week in the United States. The Great Chicago Fire raged from October 8-10, 1871.

October 31 is Halloween in some countries. On the evening of Halloween, children disguise themselves with masks and costumes and go door to door asking for treats. Halloween developed from ancient new year festivals and festivals of the dead. The ancient Celts celebrated Samhain, a harvest festival, on November 1. On

Important October events

1 Nigeria became independent in 1960.
— People's Republic of China was established in 1949.
— Free rural mail delivery began in the United States, 1896.
— First "Model T" Ford put on the market, 1908.
— Jimmy Carter, 39th U.S. president, born 1924.
2 Guinea became independent in 1958.
— Mohandas Gandhi, Indian political leader, born 1869.
— Cordell Hull, American statesman, born 1871.
3 George Bancroft, American historian, born 1800.
— Eleonora Duse, Italian actress, born 1859.
4 Lesotho became independent in 1966.
— Jean François Millet, French painter, born 1814.
— Rutherford B. Hayes, 19th U.S. president, born 1822.
— Frederic Remington, American artist, born 1861.
— U.S.S.R. launched Sputnik I, first artificial satellite, 1957.
5 Gregorian calendar introduced, 1582.
— Denis Diderot, French author, born 1713.
— Chester A. Arthur, 21st U.S. president, born 1829.
— Joshua Logan, American playwright, born 1908.
— U.S. President Harry S. Truman made the first presidential telecast address from the White House, 1947.
6 Jenny Lind, Swedish singer, born 1820.
— George Westinghouse, American inventor, born 1846.
— Le Corbusier, Swiss-born architect, born 1887.
— Anwar el-Sadat, president of Egypt, assassinated 1981.
7 First double-decked steamboat, the *Washington,* arrived at New Orleans, 1816.
— James Whitcomb Riley, American poet, born 1849.
— Niels Bohr, Danish physicist, born 1885.
8 John M. Hay, American statesman, born 1838.
— Great Chicago Fire began, 1871.
— Eddie Rickenbacker, American air ace, born 1890.
9 Uganda became independent in 1962.
— Camille Saint-Saëns, French composer, born 1835.
10 Sports Day, Japan
— Henry Cavendish, English scientist, born 1731.
— U.S. Naval Academy opened at Annapolis, Maryland, 1845.
— Fridtjof Nansen, Norwegian explorer and statesman, born 1861.
— Helen Hayes, American actress, born 1900.
11 Arthur Phillip, first governor of New South Wales, Australia, born in London, 1738.
— Eleanor Roosevelt, wife of U.S. President Franklin D. Roosevelt, born 1884.
— François Mauriac, French novelist, born 1885.
12 Christopher Columbus landed in America, 1492.
— Ralph Vaughan Williams, British composer, born 1872.
13 U.S. White House cornerstone laid, 1792.
— Rudolf Virchow, German scientist, born 1821.
— Margaret Thatcher, British prime minister, born 1925.
14 William the Conqueror won the Battle of Hastings, 1066.
— William Penn, founder of Pennsylvania, born 1644.
— Eamon de Valera, president of the Irish Republic, born 1882.
— Dwight D. Eisenhower, 34th U.S. president, born 1890.

Oct. 8—Great Chicago fire

the night before the festival, they honored Saman, the Celtic lord of death. This celebration also marked summer's end. October 31 is All Hallows' Eve in Christian cultures. It is the eve of All Saints' Day, on which Christians honor all the known and unknown saints who have died.

The calendula and cosmos are October's flowers. October's birthstones are the opal and the tourmaline.

Carole S. Angell

Quotations

October turned my maple's leaves to gold;
The most are gone now; here and there one lingers;
Soon these will slip from out the twig's weak hold,
Like coins between a dying miser's fingers.
Thomas Bailey Aldrich

There is something in October sets the gipsy blood astir;
We must rise and follow her,
When from every hill of flame
She calls, and calls each vagabond by name.
Bliss Carman

October gave a party;
The leaves by hundreds came;
The ashes, oaks, and maples,
And those of every name.
George Cooper

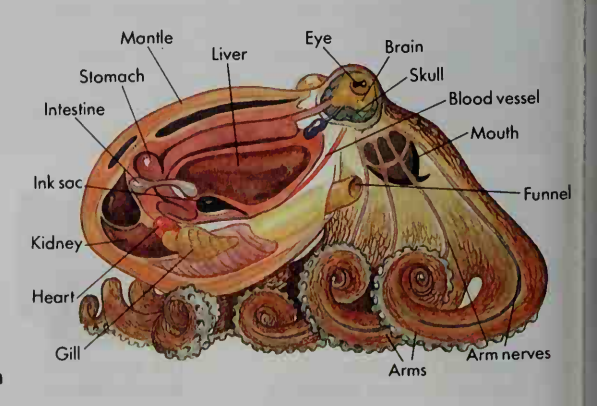
Octopuses are soft-bodied sea animals with eight long arms. Muscular suckers on the underside of each arm enable an octopus to cling tightly to rocks or prey. There are about 100 species of octopuses. The *giant octopus, left,* lives in the Pacific Ocean. The photos at the right show a cluster of transparent octopus eggs, *top,* and a newly hatched octopus.

Octopus is a sea animal with a rounded body, large eyes, and eight long arms. There are about 100 species of octopuses. The best-known species inhabit rocky, sandy, or muddy bottoms in shallow parts of oceans throughout the world. Other octopuses live in deep waters.

Octopuses vary greatly in size. The largest species, the *giant octopus* of the Pacific Ocean, weighs as much as 110 pounds (50 kilograms). It measures more than 20 feet (6 meters) from the tip of one arm to the tip of another on the opposite side of the body. The smallest species, found in the Indian Ocean, weighs less than 1 ounce (28 grams) and measures about 1 inch (2.5 centimeters) from arm tip to arm tip.

Octopuses belong to a group of animals called *mollusks.* This group also includes clams, oysters, and snails. Like squids and cuttlefish, octopuses are mollusks that have no outside shell.



The body of an octopus is soft and boneless. A fleshy, muscular covering, called the *màntle,* surrounds the main part of the body, forming a cavity that encloses the gills. An octopus breathes by drawing water into the mantle cavity. The circulation of water provides oxygen for the gills. The mantle then contracts and forces the water out through a tube called the *funnel* or *siphon.* An octopus has three hearts. Two hearts are associated with the gills and are called *gill hearts.*

The two eyes of an octopus are on each side of the head. They are similar in structure to the eyes of human beings and provide good vision.

Eight arms extend from the head of an octopus. At their base, the arms are united by a membrane web. The underside of each arm is lined with round, muscular suckers. An octopus uses its arms and suckers to move along the ocean bottom and to capture the small

The body of an octopus

WORLD BOOK illustration by Oxford Illustrators Limited

animals that it eats. The suckers can provide enormous suction, enabling the octopus to attach firmly to rocks. If an octopus loses an arm, a new one grows in its place. An octopus's mouth is a beaklike structure located beneath the head at the base of the arms.

The life of an octopus. Octopuses feed chiefly on crabs, clams, and snails. Many species also eat other octopuses. Certain octopuses make a hole in the shell of their prey and then inject a poison that paralyzes the animals.

Many sea animals—especially seals, whales, and certain fish—prey on octopuses. An octopus has various means of avoiding predators. It can swim quickly backward by forcing a powerful jet of water through its funnel. The octopus may conceal itself by discharging a cloud of inky fluid. In some cases, the shape of the ink cloud resembles the octopus and thus acts as a decoy.

An octopus also can escape danger by rapidly changing colors. Its skin contains cells called *chromatophores,* each of which contains a single-colored pigment. When the octopus is excited, these cells contract or expand, producing a color change that can startle a predator or enable the octopus to blend with the surroundings.

Octopuses reproduce sexually. The female octopus can lay more than 100,000 eggs. She cares for the eggs until they hatch into tiny, immature octopuses. The young swim at or near the surface of the water for several weeks as part of *plankton* (see **Plankton**). Many of the young are eaten by fish and other marine animals. The remaining young drop to the ocean bottom and develop into adult octopuses. Some species lay relatively large eggs. The young of these species live on the ocean bottom immediately after hatching.

Octopuses have short lives. Many live one year or less. The largest species live about three years.

Octopuses and people. Most octopuses are not regarded as dangerous to human beings. However, octopuses sometimes bite, so caution is necessary in handling them. In some countries, octopus is an important food. There are octopus fisheries in many parts of the world, most notably off Japan, in the Mediterranean, and off the northwest coast of Africa.

Scientific classification. Octopuses make up the order Octopoda in the class Cephalopoda and the phylum Mollusca. Many species belong to the genus *Octopus.* Brian Hartwick

Odd Fellows, Independent Order of, is one of the major fraternal and benevolent orders in the United States. The order was founded in England. The date of its founding is not known, but Odd Fellows' groups probably existed in the early 1700's. The members founded a system of benefits and helped one another in time of misfortune. Branches called *lodges* grew up in the various English cities, but each branch refused to admit the superior rank of any other. Adjustments were finally made, and in 1814, the Manchester Unity of the Independent Order of Odd Fellows was organized. Today, this organization has branches in various countries, but it has no connection with the order in the United States.

The American order. In 1819, the Washington Lodge of Odd Fellows was organized in Baltimore. The next year, Washington Lodge became a subordinate lodge in the Manchester Unity. Other American lodges were established later and assumed a like position.

In 1843, the American lodges separated themselves from the parent order in England. The United States grand lodge became the head of the order in America and reserved for itself the right to found new lodges in Europe. The Canadian branch operated under a separate charter until 1852. In that year, the society in Canada was merged with the grand lodge of the United States. The Order of Odd Fellows in the United States has a membership of 500,000.

Purpose and organization. The chief purpose of the Order of Odd Fellows is to give aid, assistance, and comfort to its members and their families. It also does local charitable and volunteer work. It has its own system of rites and passwords. The three links in its symbol represent friendship, love, and truth.

A local lodge can confer three degrees of membership upon an Odd Fellow. When a member has reached the highest of these three degrees, he is ready for membership in an encampment. The encampment also has three degrees of membership, the Patriarchal, the Golden Rule, and the Royal Purple. The Patriarchal is an English degree. Since 1884, there has also been a military or uniformed degree called the Patriarchs Militant.

The Rebekah lodges in Odd Fellows are chiefly for women, although some men belong. Rebekah assemblies were organized in 1851, and they continue to provide much volunteer work for the order. The headquarters of the order are at 422 Trade Street, Winston Salem, NC 27101.

Critically reviewed by the Independent Order of Odd Fellows

Ode, *ohd,* is a poem of moderate length that usually expresses exalted praise. Greek dramatists wrote *choral odes* that had three parts. Two parts, a *strophe* and an *antistrophe,* had identical meter. The third part, called an *epode,* had a contrasting meter. Pindar, of ancient Greece, wrote odes in praise of athletic heroes. He used the strophic form, which came to be called *Pindaric* (see **Pindar**). Horace, of ancient Rome, wrote odes made up of uniform stanzas, called *stanzaic* form.

English poetry, from the time of Ben Jonson, included a variety of Pindaric odes, stanzaic odes, and *irregular* odes, or those with no particular stanza structure. John Dryden wrote two irregular odes in praise of St. Cecilia. "Ode to Evening," by William Collins, is a notable stanzaic ode. The great irregular and stanzaic odes of the 1800's include William Wordsworth's "Ode: Intimations of Immortality," Percy Bysshe Shelley's "Ode to the West Wind," John Keats's "Ode on a Grecian Urn," and Alfred, Lord Tennyson's "Ode on the Death of the Duke of Wellington." Paul B. Diehl

O'Dell, Scott (1898-1989), an American author, became known for his historical novels for children. Many of his works are set in Mexico and southern California. O'Dell's first children's book, *Island of the Blue Dolphins* (1960), won the 1961 Newbery Medal. His other children's books include *The King's Fifth* (1966), *The Black Pearl* (1967), *Sing Down the Moon* (1970), and *Streams to the River, River to the Sea* (1986). O'Dell wrote three related novels about a 16-year-old Spanish boy's experiences in the New World. The series consists of *The Captive*

(1979), *The Feathered Serpent* (1981), and *The Amethyst Ring* (1982). O'Dell was born in Los Angeles.

Virginia L. Wolf

Oder River, *OH duhr,* is an important waterway in central Europe. It is about 530 miles (855 kilometers) long and drains about 46,000 square miles (119,000 square kilometers).

The Oder, also called Odra, rises in the Sudeten Mountains of the Czech Republic. It then flows northward across western Poland where it is joined by the Neisse (Nysa) River—officially Lausitzer Neisse (Nysa Łużycka). The joined rivers form most of the boundary between Poland and Germany. The Oder empties into the Baltic Sea by way of the Stettin Lagoon (see **Poland** [terrain map]). Oceangoing vessels use the Polish port of Szczecin south of the lagoon. Other major cities on the Oder include Frankfurt in Germany, the Polish cities of Wrocław and Opole, and Ostrava in the Czech Republic.

The Oder's tributaries include the Warta (Warthe) River. The Warta links the Oder with the Vistula River in Poland by the Noteć (Netze) River and a canal. Canals also link the Oder with the Polish industrial city of Gliwice and with the Havel and Spree rivers in Germany.

The Oder-Neisse boundary between Poland and East Germany was established after World War II ended in 1945. East Germany recognized this boundary in 1950. West Germany opposed the boundary until 1970, when it signed treaties with both Poland and the Soviet Union confirming the boundary. East Germany and West Germany unified in 1990. Leszek A. Kosiński

Odessa, *oh DEHS uh* (pop. 1,106,000), is a seaport city in Ukraine. It lies on the southwestern coast, near the Romanian border. Odessa is on the Black Sea, 32 miles (51 kilometers) southwest of the mouth of the Dnepr River. For location, see **Ukraine** (political map).

Odessa is one of Ukraine's industrial centers. Its refineries produce large amounts of petroleum products. Factories make machinery, automobiles, airplanes, and motion-picture equipment. Odessa is an important transfer point for rail and ocean transportation. The city is also known for its health resorts.

Odessa is built in a circular shape and slopes down toward the city's harbor. A long, spectacular stairway leads up from the harbor. The stairway is called the Potemkin Steps in memory of the crew of the ship *Potemkin,* who mutinied in Odessa during the Russian Revolution of 1905.

Historians are not sure when the first settlement was established on the site where Odessa now stands. The area was conquered by the Tatars in the 1200's, followed by the Lithuanians in the 1300's and the Ottomans in the 1500's. Russia gained control of the site in 1792 and built a port and a fortress there. In 1795, Russia named the city Odessa. In 1944, Odessa became part of the Ukrainian Soviet Socialist Republic of the Soviet Union. The Soviet Union had been formed under Russia's leadership in 1922. In 1991, following an upheaval in the Soviet Union, the Ukrainian republic declared itself an independent nation. In December of that year, the Soviet Union was dissolved. Jaroslaw Bilocerkowycz

Odets, *oh DEHTS,* **Clifford** (1906-1963), an American dramatist, is best known for his plays of social conflict written during the 1930's. His most successful works were presented by the famous Group Theatre.

Odets' one-act play *Waiting for Lefty* (1935) is about a taxi drivers' strike. It ranks among the most important of the many plays written in the 1930's that deal with the struggle of the working class. Odets' *Awake and Sing!* (1935) is less propagandistic than *Waiting for Lefty.* It tells the story of a poor Jewish family in the Bronx during the Great Depression. Odets also wrote *Paradise Lost* (1935), *Golden Boy* (1937), *Night Music* (1940), *The Big Knife* (1948), and *The Country Girl* (1950).

Odets was born in Philadelphia. He helped form the Group Theatre in 1931. He was a film scriptwriter from 1936 until shortly before his death. Frank R. Cunningham

Odin, *oh DIHN,* was the chief god in Norse mythology. In German, he is called Wotan (pronounced *WOH tuhn*). Odin became the ruler of the universe after he and his two brothers, Ve and Vili, killed the frost giant Ymir, the first living being. From Ymir's huge body, they made Midgard, the earth; and began to build Asgard, the dwelling place of the gods.

Valhalla was Odin's home in Asgard. There he feasted with the souls of heroes who had died in battle. Odin, a fearless fighter, carried a spear as his weapon, and rode an eight-legged horse called Sleipnir. He inspired ferocious human warriors called Berserkers who fought recklessly without armor and felt no wounds.

Odin was the wisest god. He gave up one eye for the right to drink from the spring of wisdom, guarded by Mimir, a supernaturally wise creature. Odin was also known for his magic powers. By wounding and hanging himself from a tree, he acquired the power of spells called *runes.* They let him predict the future, change his shape at will, and visit the underworld. Odin's sons included Thor, the god of thunder and lightning, and Balder, the god of goodness. According to Norse myths, Odin will lead the gods against the evil giants at Ragnarok, the battle that will destroy the world. He will be eaten by Fenrir, a ferocious wolf.

The Anglo-Saxons' name for Odin was Woden. It was the source of the word *Wednesday.* Carl Lindahl

Odoacer, *OH doh AY suhr* (A.D. 434?-493), was the Germanic leader who overthrew the last emperor of Rome in the West, ending the West Roman Empire.

Odoacer was probably born near the Danube River in what is now Germany. He joined the West Roman army and became a leader of barbarian troops serving the Romans. In 476, when the Roman government refused to give his troops land for settlement, Odoacer led them in a revolt. Odoacer deposed the West Roman emperor, Romulus Augustulus, and became the first barbarian king of Italy. Historians consider this event the end of the West Roman Empire. But for years, barbarian generals had been its real rulers. The emperors were symbolic rulers.

Odoacer ruled independently, though he pretended to serve Zeno, the East Roman emperor. Zeno never recognized Odoacer as ruler of Italy. In 488, Zeno sent the Ostrogoth king Theodoric to attack Odoacer. Odoacer retreated to Ravenna, where he surrendered in 493 and was executed (see **Theodoric**). William G. Sinnigen

Odometer. See **Speedometer.**

Odyssey, *AHD uh see,* an epic poem, is perhaps the most influential and most popular work in ancient Greek literature. The *Odyssey* ranks among the greatest adven-

ture stories in literature. It became a model for many later adventure stories.

According to tradition, the *Odyssey* was composed by the Greek poet Homer, probably in the 700's B.C. The central character is Odysseus (Ulysses in Latin), the king of Ithaca. The poem describes Odysseus's journey home after fighting for Greece against the city of Troy in the Trojan War. The author told about this war in the *Iliad,* another great epic poem. See **Homer**.

The *Odyssey* consists of 24 *books* (sections). The story takes place over about 10 years. The tale begins after much of the action has already occurred. This device of starting a story in the middle and returning to the start is called *in medias res.* Many later writers used it.

The *Odyssey* begins on the island of Ogygia, where Odysseus has been the prisoner of the sea nymph Calypso for seven years. At a council of the gods on Mount Olympus, Zeus decides the time has come for Odysseus to return to his wife, Penelope, in Ithaca.

The scene then changes to Odysseus's palace in Ithaca, where a group of unruly young noblemen has settled. The noblemen want Penelope to assume that her husband is dead. They demand that she marry one of them and thus choose a new king of Ithaca. Odysseus's son, Telemachus, resents the noblemen. The goddess Athena suggests that he go on a journey to seek news of his father. Telemachus agrees and leaves Ithaca.

The tale next returns to Odysseus's adventures. The god Hermes makes Calypso release Odysseus. Odysseus sails away on a raft, but the sea god Poseidon causes a storm and he is shipwrecked on the island of the Phaeacians. Nausicaa, the beautiful daughter of the Phaeacian king, discovers him.

Odysseus describes his wanderings since the Trojan War while being entertained by the Phaeacians. He tells of his visit to the land of the lotus-eaters, whose magic food makes people forget their homeland. Some of his men who ate the food wanted to stay with the lotus-eaters, but Odysseus forced them to leave with him. Odysseus and his men then sailed to an island where they were captured by Polyphemus, a one-eyed giant called a *Cyclops.* They escaped after blinding the Cyclops with a heated stake. But the Cyclops prayed to his father, Poseidon, to avenge him by making Odysseus's homecoming as difficult as possible.

After more adventures, the ship carrying Odysseus and his men landed on the island of the enchantress Circe. Circe changed Odysseus's men into pigs and made Odysseus her lover. She told Odysseus that to get home, he must visit the underworld to consult the prophet Teiresias. In the underworld, Odysseus saw the ghosts of his mother and of Trojan War heroes. He also witnessed the punishment of sinners.

Teiresias warned Odysseus of the dangers awaiting him, and Circe told him how to sail past the sea monsters Scylla and Charybdis. Circe also warned him about the Sirens, sea nymphs who use their beautiful singing to lure sailors to death on a magic island. Odysseus's ship sailed past these dangers and seemed ready to reach Ithaca without further trouble. But some of Odysseus's men stole and ate the sacred cattle of the sun on the island of Thrinacia. As punishment, the ship was destroyed by a thunderbolt and the men drowned. Odysseus was washed up on Ogygia, where the story began.

Red-figure painting (about 475 B.C.) on a terra cotta vase; Granger Collection

Odysseus encountered the Sirens during his voyage home. The Sirens, part bird and part woman, lured seamen to their death with beautiful singing. Odysseus had himself tied to the mast so he could safely enjoy the singing.

Odysseus returns home. After Odysseus finishes his story, the Phaeacians take him to Ithaca. Athena tells him of the noblemen in his palace and advises him to return home in disguise. Odysseus goes to his palace disguised as a beggar. Penelope has agreed to marry the man who can string Odysseus's huge bow and shoot an arrow through 12 axes. Odysseus wins the contest, kills the noblemen, and is reunited with Penelope.

The *Odyssey* as literature. The *Odyssey* is a skillfully told adventure story. The story combines realistic accounts of life in ancient Greece and elements of historical events with fairy tales about imaginary lands.

The work also contains skillful characterization. Odysseus represents the model of a man of courage and determination. In spite of many setbacks, he never abandons his goal of returning home. But he has other human traits that keep him from being only a symbol. He enjoys life, even while struggling to get home. He is restless, clever, and even tricky and is able to invent lies easily. In fact, some later Greek dramatists made Odysseus a symbol of deceit. Penelope stands for the faithful, loving wife. Telemachus symbolizes the youth who matures by facing a difficult challenge. The travels of Odysseus and Telemachus may represent the human journey through life and the search for self-fulfillment and self-knowledge. Cynthia W. Shelmerdine

Oedipus, *EHD uh puhs,* was a king of Thebes in Greek mythology. Many ancient authors wrote different versions of the story of Oedipus. The following version is based largely on *Oedipus Rex,* a tragedy by the Greek playwright Sophocles.

The *oracle* (prophet) of Delphi told King Laius of Thebes that a son born to his wife, Queen Jocasta, would kill him (see **Delphi**). After Jocasta gave birth to a son, Laius ordered the baby taken to a mountain and left to die. However, a shepherd rescued the child and brought him to King Polybus of Corinth. Polybus adopted the boy and named him *Oedipus.*

Oedipus grew up in Corinth. As a young man, he learned from the oracle that he would kill his father and marry his mother. Believing that Polybus was his father, Oedipus tried to avoid the prophecy by fleeing Corinth. On the road to Thebes, he quarreled with a man and killed him. The stranger was King Laius.

Near Thebes, Oedipus encountered a monster called the Sphinx. She had a woman's head, a lion's body, and a bird's wings. The Sphinx killed everyone who could not solve this riddle: What has one voice and becomes four-footed, two-footed, and three-footed? The Sphinx asked Oedipus the riddle, which no one had solved. He answered: Man, who crawls on all fours as a baby, then walks on two legs, and finally needs a cane in old age. The Sphinx killed herself because Oedipus had solved the riddle. Oedipus was rewarded by being made king of Thebes. He married Jocasta, the widowed queen.

Several years later, a plague struck Thebes. The oracle said it would end when the murderer of Laius had been driven from Thebes. Oedipus investigated the murder and came to realize that Laius was the man he had killed on the road to Thebes. He then discovered that Laius was his father and Jocasta his mother. Oedipus blinded himself, and Jocasta hanged herself. Oedipus was banished from Thebes. He died at Colonus, near Athens. John Hamilton

Painting on a cup (about 465 B.C.) by an unknown Greek artist. Vatican Museums, Rome (SCALA/Art Resource)

Oedipus, a hero in Greek mythology, solved the riddle of the Sphinx. The Thebans rewarded him by making him king.

Oedipus complex, *EHD uh puhs,* a concept used in psychoanalysis, is a child's unconscious desire for the exclusive love of the parent of the opposite sex. This desire includes jealousy toward the parent of the same sex and the unconscious wish for that parent's death.

The term *Oedipus complex* was first used by the Austrian physician Sigmund Freud. It comes from the myth of Oedipus, a Greek hero who unknowingly killed his father and married his mother (see **Oedipus**). Freud used the term to describe the unconscious feelings of children of both sexes toward their parents. However, later researchers used the term *Electra complex* for the complex in girls. According to Greek legend, a woman named Electra helped plan the murder of her mother.

Freud believed that the Oedipus complex is a normal part of human psychological growth. The Oedipal phase of development is commonly considered to last from the age of $2\frac{1}{2}$ to 6. During this period, children experience intense feelings—love and hate, yearning and jealousy, fear and anger—that produce emotional conflicts. Most people outgrow the Oedipal phase, but some mentally ill individuals have a strong Oedipus complex as adults. According to Freud, the principal reason for the weakening of the complex in boys is the fear of punishment from the father.

Freud thought that all peoples experience the Oedipus complex. But many anthropologists and researchers in psychoanalysis doubt that the complex exists in certain non-Western societies. They believe it develops as a result of a person's social environment and does not occur in everyone. Nancy C. Andreasen

Oersted, *UR stehd,* **Hans Christian** (1777-1851), a Danish physicist and chemist, laid the foundation for the science of electromagnetism (see **Electromagnetism**). In 1820, he noticed that the needle of a compass wavered every time he put it near a wire carrying a current. He had discovered that every conductor carrying an electric current is surrounded by a magnetic field. Oersted is also credited with producing the first aluminum, in 1825 (see **Aluminum** [The first aluminum]). He wrote *Spirit of Nature* (1850). Oersted was born in Rudkøbing, Denmark. Richard G. Olson

Offenbach, *AW fuhn bahk,* **Jacques,** *zhahk* (1819-1880), a French composer, created the French style of operetta. His operettas are humorous, witty, and satirical. He enjoyed poking fun at the politics and society of his day, and quoting familiar themes from other compositions (especially operas). Offenbach's success internationally helped to establish operetta as an accepted musical form and led to the development of musicals in the United States in the 1900's.

Many of Offenbach's operettas are called *opéras bouffes* (comic or light operas). He eventually completed more than 90 works for the stage. His first success was *Orpheus in the Underworld* (1858). His most popular compositions appeared in the 1860's. They include *La Belle Hélène* (1864), *La Vie Parisienne* (1866), *La Grande-Duchesse de Gérolstein* (1867), and *La Périchole* (1868). In 1877, he began his most famous work, the opera *The Tales of Hoffmann,* which was unfinished at his death. See **Operetta**.

Offenbach was born in Cologne, Germany. He moved to Paris in 1833 to study the cello, and for many years had a successful career as a cellist. He became a conductor at the Théâtre-Français in 1850. In 1855, he founded the Bouffes-Parisiens, a theatrical company that staged many of his operettas. Offenbach became a French citizen in 1860. Katherine K. Preston

Office of . . . See articles on offices listed under their key word, as in Management and Budget, Office of.

Office work is the process of recording, storing, and distributing the information needed to operate a business. The managers of the business use this information to make administrative decisions.

Millions of people in industrialized countries are employed as office workers. They include bookkeepers and accounting technicians, clerk-typists, secretaries, and word-processing technicians. Office workers do not include people involved in such activities as buying, selling, or management.

An office may receive information by telecommunications, by mail, or by computer. An office worker must have skill in language and arithmetic to handle this and other business information properly. Almost all office jobs require at least a high school education. Many employers prefer people who have taken courses beyond the high school level. A person can get such advanced training at a community college, junior college, or business or vocational school. This training may include instruction in operating calculators, copying machines, microfilm equipment, and personal computers.

An office requires a staff of managers to plan and direct work. As a business grows, so does the amount of information that must be handled by its office workers. The managers coordinate the activities of these employees so that accurate records can be kept concerning correspondence, inventory, payroll, sales, and taxes.

Recording information. Business information may be recorded by hand or by machine. Some handwritten information may be used in the form in which it is recorded. For example, a secretary may take a telephone message for someone who is out of the office. Such information does not have to undergo further processing before it can be used. Other types of information may be recorded by hand before being processed through a machine. For example, a stenographer takes notes in shorthand and then types letters from the notes.

Information can also be recorded directly into a machine. A manager may dictate a letter into a dictating machine and have a secretary transcribe the message into a personal computer.

Today, many secretaries use personal computers equipped with word-processing software to do the work that otherwise would be done with typewriters. Some of these computers are small enough to be held in the worker's lap. Personal computers have a keyboard similar to that of a typewriter. The computer may be linked to a printer that can quickly produce copies of the original material.

Many office workers still use electric, electronic, or word-processing typewriters. Electric typewriters have a motor to provide power, and so the typist only needs to touch the keys lightly. Electronic typewriters can automatically perform such functions as setting margins and underlining. With word-processing typewriters, the operator enters the material onto a magnetic card, tape, or disk. The word processor can then print copies of the material.

Bookkeepers can also record information directly into a machine. For example, they may enter data into a computer by using *spreadsheet* software. With this software, the user can enter numbers and other information into special boxes displayed on the computer screen. The computer then uses the data to tabulate and print financial reports automatically.

Storing information. A business firm stores information to provide a record of its transactions. Many companies use computers and other high-capacity data-processing equipment to store information. A worker may enter information into a computer by using a keyboard. The signals that make up the information are sent to the computer's *memory* for storage. A computer can also receive information from an *optical scanner,* a machine that "reads" handwritten or printed material directly off a page.

Another method of storing information, called *micrographics,* records printed material photographically and reduces the image. It saves filing space and keeps records in good condition for a long time. Micrographics uses filmstrips called *microfilm* or sheets of film called *microfiche.* About 3,000 business letters can be photographed on a strip of microfilm 16 millimeters ($\frac{5}{8}$ inch) wide and 100 feet (30 meters) long. The strip can be wound up in a roll that takes only about 16 cubic inches (262 cubic centimeters) of space. About 400 business letters can be photographed on a sheet of microfiche that measures 105 by 148 millimeters ($4\frac{1}{8}$ by $5\frac{13}{16}$ inches). A form of microfiche called *ultrafiche* can display over 3,000 business letters. Microfilm and microfiche are read using machines that enlarge the images.

Distributing information. Messenger service ranks as one of the oldest methods of distributing information within an office. Messengers visit the various departments of a company at regular times daily to pick up and deliver communications.

Information to be distributed to many people in an office may be duplicated on paper with a copying machine. Copying machines make copies quickly and inexpensively, often through a process called *xerography.* In addition, a computer can quickly find any information in its memory and then print copies.

Messages also can be transmitted within an office—or around the world—electronically. For example, workers can exchange information over computer networks by *e-mail,* also called *electronic mail.* E-mail can be sent to many individuals simultaneously. Richard M. Hodgetts

Officer. See Rank, Military; Reserve Officers Training Corps.

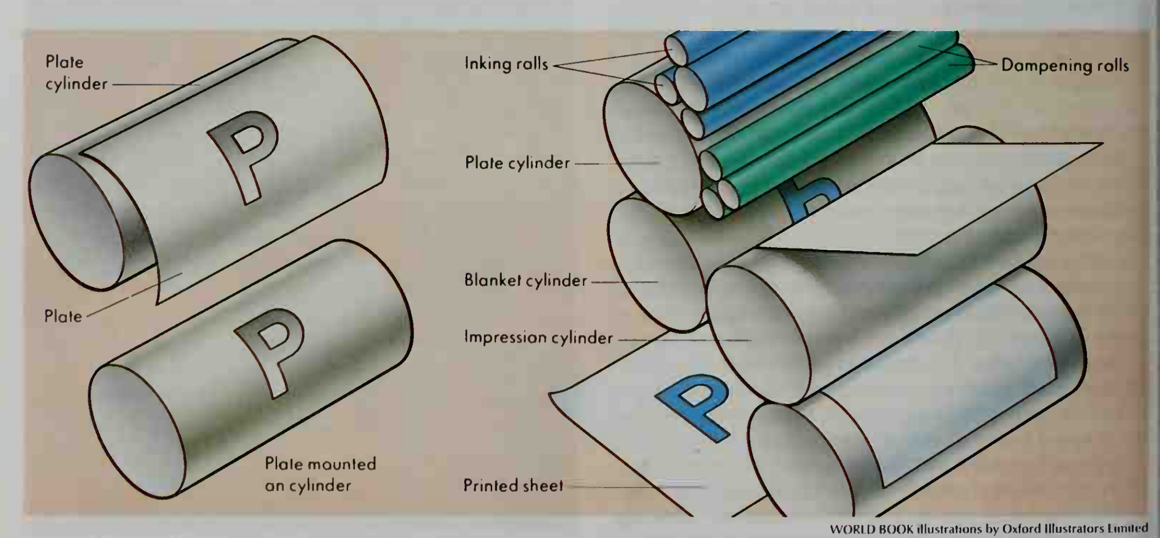
Offset is a printing process in which the printing is done first on the rubber surface of a rotating cylinder. The impression is then transferred to paper by the pressure of other cylinders. The term *offset* describes the transfer, or offsetting, of the ink from a printing plate to the rubber and then to the paper.

All ordinary offset printing is done from the metal surfaces of lithographic plates (see **Lithography**). The material to be printed is transferred onto the plates through a special photographic process. The plates are chemically treated so that only the traced design of the print will take up the ink. But the offset process is used for other methods also. Some printing is done from ordinary type and cuts, some from thin plastic relief or letterpress plates, some from gelatin surfaces, and some from *intaglio* plates, which are metal sheets that carry the ink in sunken lines.

Offset lithography is usually done on a press having three cylinders. A lithographic plate is wrapped around the first cylinder. This plate is a sheet of aluminum or zinc about as thick as heavy paper. The plate prints on a second cylinder, which is covered by a rubber blanket. The impression on the rubber is then printed on the paper carried by the third cylinder. The third cylinder is equipped with steel fingers, called *grippers,* to hold the paper in position while it is squeezed against the rubber surface. Three-cylinder presses of this type can turn out 10,000 to 12,000 impressions an hour.

These cylinders are almost hidden while the press is in operation. They are covered by a great number of rollers which supply the lithographic plate with ink and water. The cylinders are also concealed by the mechanism for feeding and removing the sheets of paper.

Offset has several advantages over other types of printing. The elastic rubber transfers the impression to a rough surface as easily as to a smooth one. This makes it possible to print on rough paper, as well as on tin, Celluloid, and other substances. Another advantage of offset is that the rubber on the cylinder fits easily to uneven surfaces. This reduces the time workers must spend preparing the presses for printing.



Offset was developed in the early 1900's in the United States as a method of printing tin sheets for making cans and boxes. It has recently been applied to almost every class of printing, from the cheapest to the most expensive. Offset has replaced the older forms of lithography in which the impression was made directly on the paper from stone or metal plates. An offset press can turn out bank notes, letterheads, magazine covers, mail-order catalogs, newspapers, posters, and stock certificates. In the United States, the offset press is used to print most daily newspapers. Offset is combined with *rotogravure,* another printing process, to make colored illustrations that are clear and delicate. It is also used for facsimile reproduction of old books.

Offset is still being improved and applied to new purposes. The wearing qualities of the lithographic plates are being improved. Offset presses have been designed to print on a *web* (continuous sheet on a spool) of paper. The paper on this *web press* is passed between two rollers covered with rubber blankets, printing on both sides at the same time. J. C. McCracken

Offutt Air Force Base, Nebraska, is headquarters of the United States Strategic Command (USSTRATCOM), an interservice command for nuclear offensive forces. In a nuclear war, USSTRATCOM would control all U.S. long-range nuclear weapons, including submarine-launched missiles. USSTRATCOM was created in 1992.

The base covers 4,044 acres (1,637 hectares) south of Omaha. On this site, the U.S. Army established Fort Crook in 1891. In 1921, the Army completed construction of an airfield there. In 1924, the airfield was named Offutt Field after First Lieutenant Jarvis J. Offutt, a pilot killed in World War I. In 1946, the Army Air Forces gave the name Offutt Field to all of Fort Crook. In 1948, the newly created U.S. Air Force acquired Offutt Field and named it Offutt Air Force Base. Offutt served as the headquarters of the Strategic Air Command from 1948

O'Flaherty, *oh FLA huhr tee,* **Liam,** *LEE uhm* (1896-1984), was an Irish writer of novels and short stories. He wrote many of his works in Gaelic and translated them into English. O'Flaherty was born on Aug. 28, 1896. Much of his fiction vividly depicts the barren, rocky landscape and remote villages of the Aran Islands, where he was born and raised. Other works, reflecting his later life, describe grinding poverty in impersonal cities.

O'Flaherty's best-known novel is the harshly realistic *The Informer* (1925). He also wrote *The Black Soul* (1924), *The Assassin* (1928), *Skerrett* (1932), and *Famine* (1937). In these novels, young, poor, and disadvantaged people struggle against overwhelming odds and lose.

O'Flaherty wrote many short stories in economic, lyrical prose. Many are collected in *Spring Sowing* (1924) and *The Stories of Liam O'Flaherty* (1956). These stories portray children, peasants, or animals with emotions, who are helpless in the face of passing time and the destructive force of nature. Janet Egleson Dunleavy

Ogden, *AHG dehn* or *AWG dehn* (pop. 77,226), is one of the largest cities in Utah. It lies in the northern part of the state, 35 miles (56 kilometers) north of Salt Lake City. For location, see Utah (political map). Ogden and Salt Lake City form part of a metropolitan area of 1,333,914.

Ogden's industries process agricultural products, produce missiles and automobile air bags, and extract minerals from the Great Salt Lake. Regional headquarters of the Internal Revenue Service and the Forest Service are in the city. Ogden is the home of Weber State University and the Utah Schools for the Deaf and Blind.

Mormons came to the Ogden region in 1848. Ogden was incorporated in 1851 and grew rapidly after becoming a link in the transcontinental railroad system in 1869. The Golden Spike, driven near Ogden in May 1869, completed the railroad. Ogden was named for Peter Skene Ogden, an early fur trader.

Ogden is the seat of Weber County. It has a mayor-council form of government. Pat Bean

Oglethorpe, *OH guhl THAWRP,* **James Edward** (1696-1785), an Englishman, was the founder of the colony of Georgia. He was born on Dec. 22, 1696, in London and attended Eton and Oxford. He joined the British Army at 14. He was elected to Parliament in 1722. There, he became interested in people who had been imprisoned for not paying their debts. Oglethorpe hoped to help them by establishing an American colony for debtors. In 1732, he and a group of associates received a charter from George II for the colony, which was to be established on territory between the Savannah and Altamaha rivers. Parliament also granted him $50,000.

Oglethorpe and about 120 colonists arrived in America in January 1733. The next month, he set up his first settlement where the city of Savannah now stands. Few debtors ever came to the new colony, however. Oglethorpe governed wisely for nine years and drove invading Spanish troops back into Florida. He defeated the Spaniards badly in the Battle of Bloody Marsh on St. Simons Island, in 1742.

Oglethorpe was so much in debt from his loans to colonists that he had to return to England in 1743. His enemies called him a coward for not capturing St. Augustine, Florida, when he attacked the Spaniards there in 1743. A court-martial dismissed the charges. He and the other trustees returned the Georgia charter to George II in 1752, and Georgia became a royal province.

O'Hara, John (1905-1970), was an American novelist and short-story writer. He gained fame for his realistic observations on the manners and morals of the American middle class. O'Hara set a number of his novels and stories in the fictional town of Gibbsville, Pennsylvania.

John Henry O'Hara was born on Jan. 31, 1905, in Pottsville, Pennsylvania. He worked as a journalist until he turned to fiction following the success of his first novel, *Appointment in Samarra* (1934). The novel is an ironic picture of upper middle-class life in a Pennsylvania city. O'Hara's other important novels include *Butterfield 8* (1935), *Ten North Frederick* (1955), *From the Terrace* (1958), and *Elizabeth Appleton* (1963). Many of O'Hara's books were made into motion pictures, and two of his novels, *Hope of Heaven* (1938) and *The Big Laugh* (1962), are set in Hollywood.

O'Hara received special praise for his short fiction. His collections of stories include *The Doctor's Son* (1935), *Sermons and Soda Water* (1960), *The Cape Cod Lighter* (1962), *The Hat on the Bed* (1963), and *Good Samaritan* (published in 1974, after his death). O'Hara collaborated with composer Richard Rodgers and lyricist Lorenz Hart to turn his story sequence *Pal Joey* (1940) into a musical comedy of the same name. Barbara M. Perkins

O'Hara, Mary (1885-1980), was the pen name of Mary O'Hara Alsop, an American author. She wrote of people on the plains and their love for horses in her novels *My Friend Flicka* (1941) and *Thunderhead* (1943). She also wrote *The Son of Adam Wyngate* (1952), which is a novel of spiritual experiences. She was born on July 10, 1885, in Cape May Point, New Jersey.

O'Higgins, Bernardo (1778-1842), was the chief liberator of Chile and its first leader after independence. He headed the nation from 1817 to 1823.

In 1814, O'Higgins became commander in chief of rebel forces fighting to gain Chilean independence from Spain. In October, the Spaniards defeated the rebels at the Battle of Rancagua, and O'Higgins fled with his army to Argentina. There, he joined forces with the Argentine general José de San Martín. In 1817, the combined armies crossed the Andes Mountains and defeated the Spaniards at Chacabuco, near Santiago. O'Higgins was then named *supreme director* of Chile. O'Higgins and San Martín won a final victory over the Spanish forces in 1818 at the Maipo River.

O'Higgins backed a number of reforms for Chile but met with strong opposition from aristocrats, provincial chiefs, and the Roman Catholic Church. Lack of support for his policies caused him to resign in 1823.

Bernardo O'Higgins Riquelme was born on Aug. 20, 1778, in Chillán, Chile. His Irish-born father, Ambrosio O'Higgins, was a colonial official in the service of Spain.

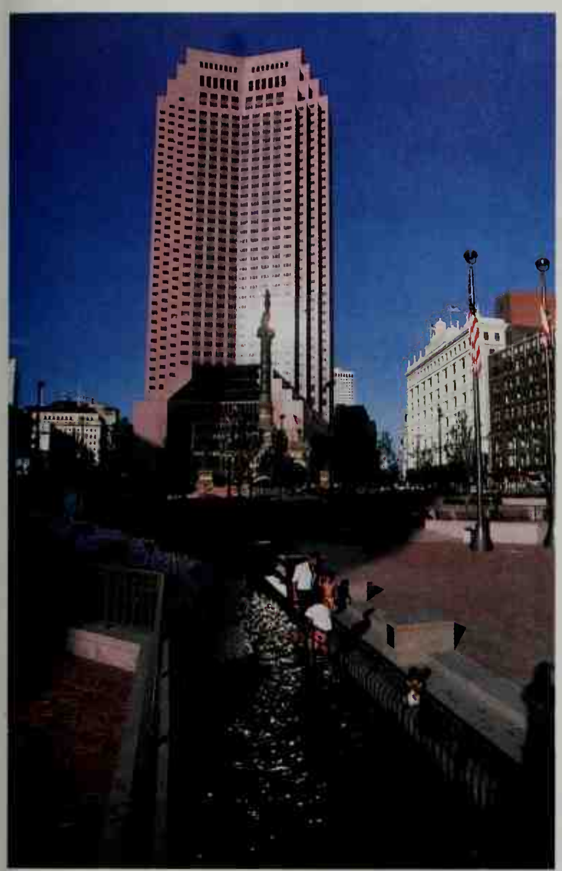
A scenic meadow in central Ohio forms part of the Appalachian Plateau region. This region includes rolling hills and valleys and some of the state's largest forests.

Ohio *The Buckeye State*

Ohio is one of the leading industrial states in the United States. Its industries produce motor vehicles, machine parts, metal products, processed foods, steel, and many other products. Ohio ranks 7th among the states in population, though it is 35th in area. Columbus is Ohio's largest city and the state capital. Cleveland, the state's chief industrial center, is Ohio's largest metropolitan area.

Ohio took its name from the Iroquois Indian word meaning *something great.* The Iroquois used the word for the Ohio River, which forms the state's southeastern and southern borders. Ohio is called the *Buckeye State* because of the buckeye trees that once grew plentifully on its hills and plains. Pioneers cut down many of the buckeyes to build log cabins.

In 1803, Ohio became the first state to be carved out of the Northwest Territory. Ohio later served as an important link to the West as canals, railways, and roads crossed the state. It was called the *Gateway State.*



The contributors of this article are Richard J. Hopkins, Former Associate Professor of History at Ohio State University; and Thomas W. Schmidlin, Associate Professor of Geography at Kent State University.

Several natural advantages helped Ohio become a great manufacturing state. Ohio has an abundant supply of water and large deposits of coal, salt, and other important minerals. Its central location, near raw materials and major markets, has helped attract many large industries. Ohio ranks high among the states in the manufacture of motor vehicles and motor vehicle parts, industrial machinery, food products, and steel.

But manufacturing is only part of the Ohio economy. A majority of the state's workers are employed in service industries, which include such activities as education, health care, and trade. Cleveland and Columbus are important financial centers of the United States. In addition, Cleveland is among the nation's leading health care centers and Columbus is an important distribution center. Cincinnati, Ohio's third-largest city, is also an important center of manufacturing and trade.

Farmland covers about half of Ohio. Soil in the Till Plains area of western Ohio is especially fertile. Ohio is a major producer of corn and soybeans.

Ohio claims the title of the *Mother of Presidents.*

Interesting facts about Ohio

WORLD BOOK illustrations by Kevin Chadwick

The first electric traffic signal lights on record were invented by James Hoge of Cleveland. They were installed in Cleveland on Aug. 5, 1914, at Euclid Avenue and East 105th Street by the American Traffic Signal Company. Brackets on poles at each corner held red or green lights 15 feet (4.5 meters) above the street. When the lights were about to change, a bell rang to warn the motorists.

First traffic lights

The first public weather forecasting service in the United States was started in Cincinnati. Cleveland Abbe, the director of the Cincinnati Observatory, issued the first of his daily statements of "probabilities" on Sept. 1, 1869. He predicted prevailing easterly and southerly winds for September 2.

The first book matches were manufactured by the Diamond Match Company at its factory in Barberton in 1896. The company had obtained the patent of book matches from the man who invented them, Joshua Pusey, a Philadelphia attorney. The patent date, Sept. 27, 1892, appeared on Diamond matchbooks for years.

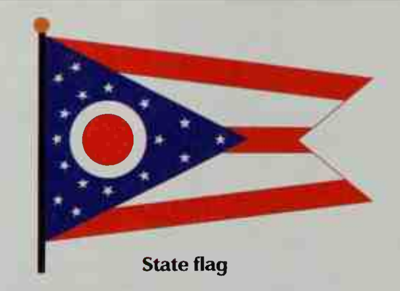
The oldest known watercraft in North America is a dugout canoe built about 1600 B.C. It was found in 1977 in a peat bog at the head of the Vermilion River in Ashland County. The canoe is now on display at the Cleveland Museum of Natural History.

Oldest watercraft

Seven Presidents of the United States were born in Ohio, more than in any other state except Virginia. In historical order, the Presidents born in Ohio were Ulysses S. Grant, Rutherford B. Hayes, James A. Garfield, Benjamin Harrison, William McKinley, William Howard Taft, and Warren G. Harding. William Henry Harrison was living in Ohio when he became President of the United States.

Two of the nation's most famous astronauts were born in Ohio. Neil A. Armstrong, the first person to set foot on the moon, was born in Auglaize County near Wapakoneta. John H. Glenn, Jr., the first American astronaut to orbit the earth, was born in Cambridge and grew up in New Concord. He was elected to the United States Senate from Ohio in 1974.

Many famous inventors also came from Ohio. Thomas A. Edison, the wizard of electricity, developed his scientific curiosity as a small boy in Milan. Orville and Wilbur Wright made test flights in their first power-driven airplane from a field near Dayton. Charles F. Kettering of Dayton developed a self-starter for automobiles. The aluminum-refining process was discovered by Charles M. Hall of Oberlin.

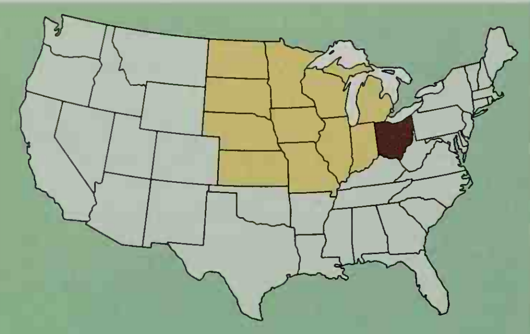


Rockwell International

An aircraft manufacturing plant in Columbus produces bomber parts for the United States Air Force. Ohio ranks among the leading manufacturing states.

Ohio in brief

Symbols of Ohio

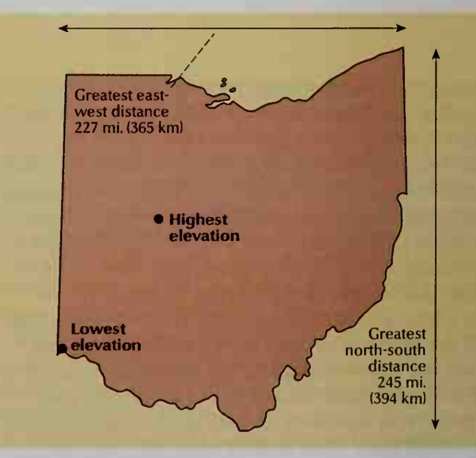


The state flag was adopted in 1902. The triangle represents Ohio's hills and valleys, and the stripes symbolize roads and waterways. The 17 stars stand for Ohio as the 17th state. The white circle with a red center represents Ohio's initial and the buckeye nut. The seal, adopted in 1967, bears a sheaf of wheat and a bundle of 17 arrows. The sun rising over mountains shows that Ohio was the first state west of the Allegheny Mountains.

State flag

State seal

Ohio (brown) ranks 35th in size among all the states and 11th in size among the Midwestern States (yellow).



The State Capitol is in Columbus, the capital of Ohio since 1816. Earlier capitals were Chillicothe (1803-1810, 1812-1816) and Zanesville (1810-1812).

General information

Statehood: March 1, 1803, the 17th state.
State abbreviations: O. (traditional); OH (postal).
State motto: *With God, All Things Are Possible.*
State song: "Beautiful Ohio." Words by Ballard MacDonald, music by Mary Earl.

Land and climate

Area: 41,328 sq. mi. (107,040 km²), including 376 sq. mi. (973 km²) of inland water but excluding 3,499 sq. mi. (9,063 km²) of Great Lakes water.
Elevation: *Highest*—Campbell Hill in Logan County, 1,550 ft. (472 m) above sea level. *Lowest*—433 ft. (132 m) above sea level along the Ohio River in Hamilton County.
Record high temperature: 113 °F (45 °C) near Gallipolis on July 21, 1934.
Record low temperature: −39 °F (−39 °C) at Milligan, near New Lexington, on Feb. 10, 1899.
Average July temperature: 73°F (23 °C).
Average January temperature: 28°F (−2 °C).
Average yearly precipitation: 38 in. (97 cm).

Important dates

c. 1670 — La Salle probably became the first white person to explore the Ohio region.

1788 — The first permanent white settlement in Ohio was established at Marietta.

1803 — Ohio became the 17th state on March 1.

1832 — The Ohio and Erie Canal was completed.

1914 Ohio passed the Conservancy Act after floods in 1913.

1922 The Miami River Valley flood-control project was completed.

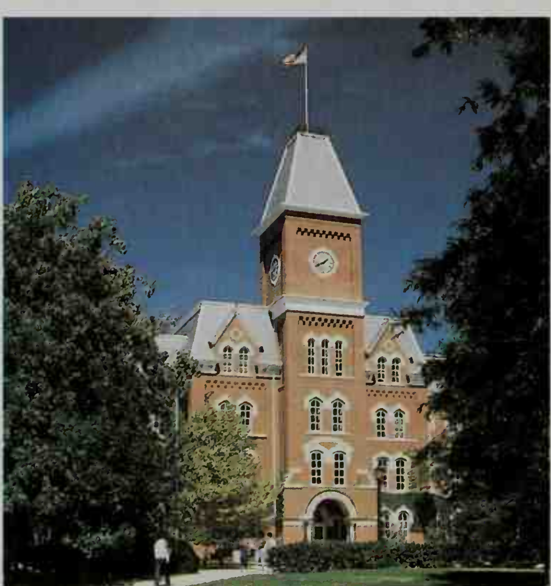
1955 The Ohio Turnpike was opened to traffic.

1971 Ohio adopted a state income tax.

1993 Voters approved a $200 million state park and recreation area improvement project.

People

Population. The 2000 United States census reported that Ohio had 11,353,140 people. The state's population had increased by nearly 5 percent over the 1990 census figure, 10,847,115. According to the 2000 United States census, Ohio ranks 7th in population among the 50 states.



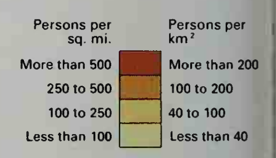
About 85 percent of Ohio's people live in the state's metropolitan areas. About half of the people live in the three largest metropolitan areas of Ohio—Cincinnati, Cleveland, and Columbus.

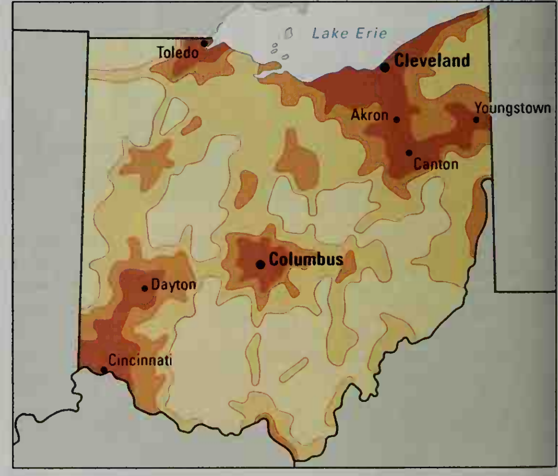
In all, Ohio has 15 metropolitan areas. Ten of these areas lie entirely within the state. Five metropolitan areas are partly in Ohio and partly in one or more of the bordering states of Indiana, Kentucky, and West Virginia (see **Metropolitan area**). For the names and populations of the metropolitan areas, see the *Index* to the political map of Ohio.

Columbus, with a population of 711,470, ranks as the largest city in Ohio. Five other cities in the state have populations of 100,000 or more. These cities are Cleveland, Cincinnati, Toledo, Akron, and Dayton. For more information on Ohio's cities, see the articles listed in the *Related articles* at the end of this article.

The largest population groups in Ohio include people of German, Irish, and English descent. About 11 percent of the state's people are African Americans. People of Hispanic and Asian origin each account for less than 2 percent of Ohio's population.

Schools. The first school in Ohio opened in 1773 at Schoenbrunn, near present-day New Philadelphia. It was set up for Indian children by David Zeisberger, a Moravian missionary. Ohio's public-school system began in





J. Kevin Fitzsimons, Ohio State University

Ohio State University at Columbus has one of the largest student populations of any campus in the United States. University Hall, *shown here,* is located in the center of the campus.

Population density

About 85 percent of Ohio's people live in the state's metropolitan areas. About half of the state's people live in the metropolitan areas of Cincinnati, Cleveland, and Columbus.

Toledo Chamber of Commerce

The Toledo Festival of the Arts features arts and crafts, food, and entertainment. This popular event takes place annually over the Labor Day weekend.

1825, and public high schools were authorized in 1853. During the 1800's, several Ohio educators wrote school textbooks that were used in public schools throughout the United States. The most famous of these educators was William H. McGuffey (see **McGuffey, William H.**).

Many colleges were founded in Ohio in the 1800's. Oberlin College, established in 1833, became the first college in the United States for both men and women.

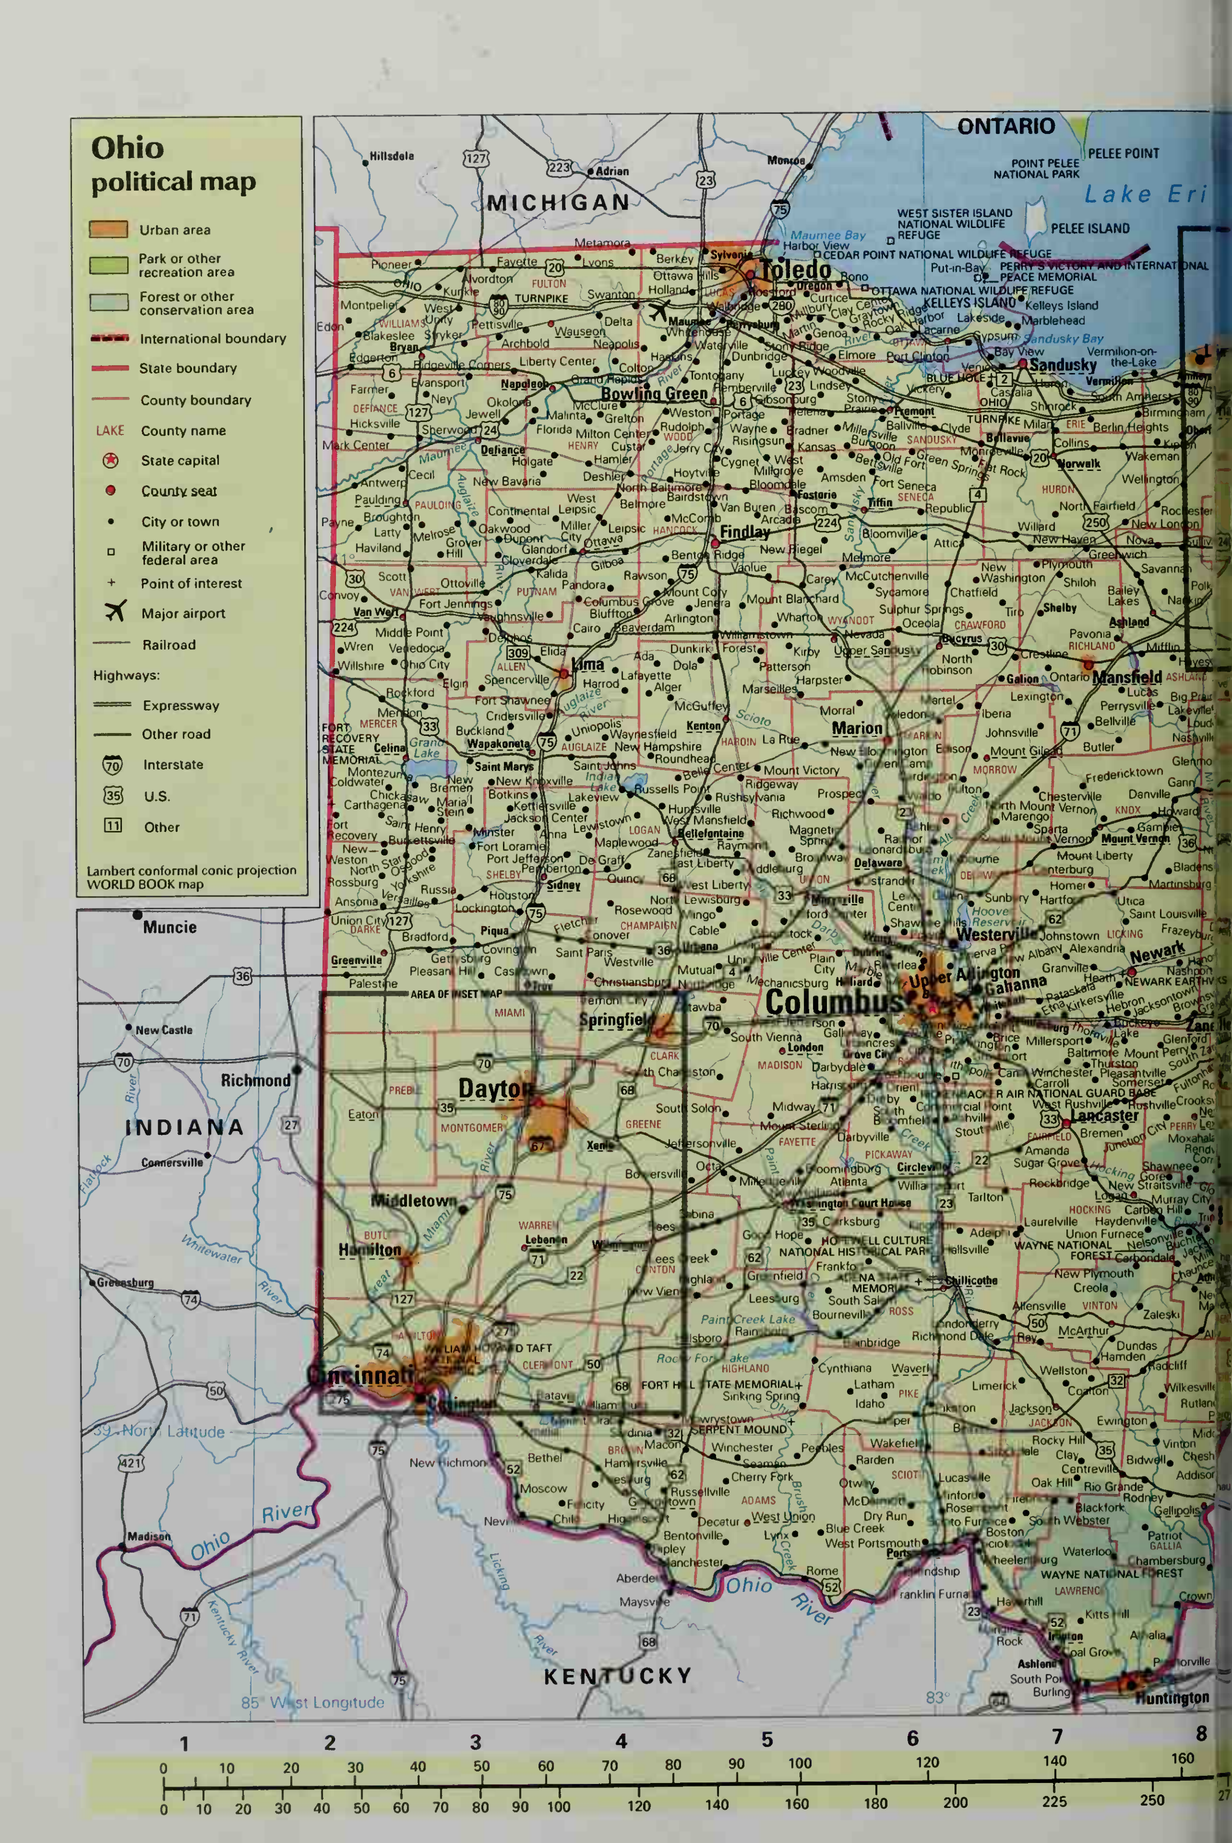
The State Board of Education supervises all elementary schools and high schools in Ohio. This board consists of 11 members elected to four-year terms and eight members appointed by the governor. These members appoint the state superintendent of public instruction. Ohio law requires children from age 6 through 17 to attend school. For the number of students and teachers in Ohio, see **Education** (table).

Libraries. A subscription library opened at Belpre in 1795. In 1804, the famous Coonskin Library was founded at Ames (now Amesville). Pioneers bought its first books with animal skins. Many of these books have been preserved by the Ohio Historical Society in Columbus. The State Library of Ohio in Columbus was established in 1817 as a reference library for state officials.

The Cleveland Public Library is one of the biggest in the United States. Other large libraries in Ohio include the Public Library of Cincinnati and Hamilton County, the University of Cincinnati Library, and the Ohio State University Library in Columbus. Columbus is Ohio's largest library center. The library of the Rutherford B. Hayes Presidential Center in Fremont honors the 19th U.S. president. It opened in 1916 and was the nation's first presidential library. The Cincinnati Historical Society highlights early Ohio and metropolitan Cincinnati.

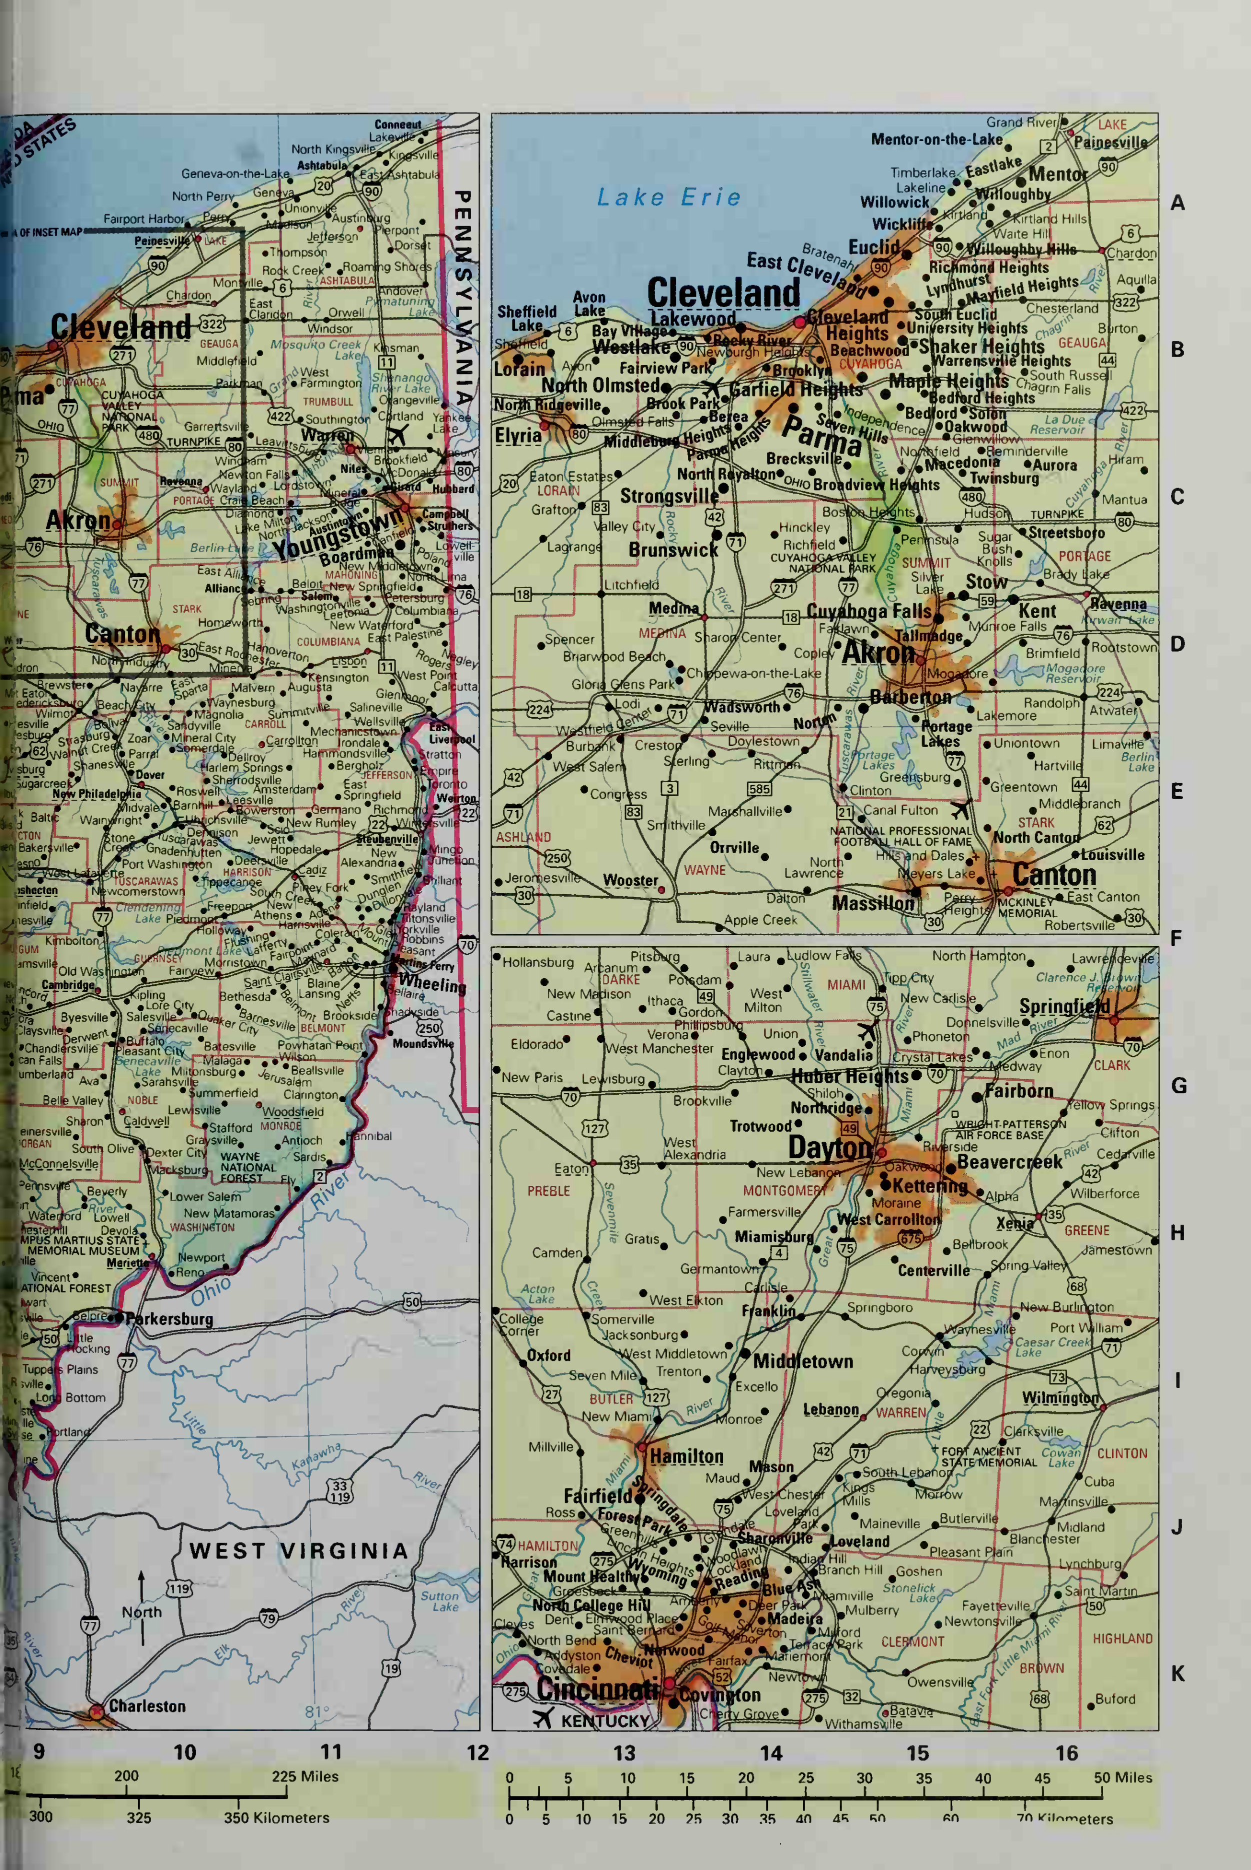
Cleveland Museum of Art

The Cleveland Museum of Art exhibits one of the finest collections of art in the world. The visitors shown in this photograph are viewing paintings in the Renaissance Gallery.



Museums. The Cleveland Museum of Art, the Cincinnati Art Museum, and the Toledo Museum of Art all own renowned collections of art from many different periods and cultures. The Taft Museum in Cincinnati displays paintings and Chinese porcelain. The U.S. Air Force Museum at Wright-Patterson Air Force Base near Dayton exhibits old and modern airplanes. The Rock and Roll Hall of Fame and Museum in Cleveland has displays and interactive exhibits about the history of rock music.

Universities and colleges



This table lists the universities and colleges in Ohio that grant bachelor's or advanced degrees and are accredited by the North Central Association of Colleges and Schools.

Name	Mailing address
Air Force Institute of Technology	Wright-Patterson Air Force Base
Akron, University of	Akron
Antioch College	Yellow Springs
Antioch University	Yellow Springs
Antioch University McGregor	Yellow Springs
Art Academy of Cincinnati	Cincinnati
Ashland University	Ashland
Athenaeum of Ohio	Cincinnati
Baldwin-Wallace College	Berea
Bluffton College	Bluffton
Bowling Green State University	Bowling Green
Capital University	Columbus
Case Western Reserve University	Cleveland
Cedarville University	Cedarville
Central State University	Wilberforce
Cincinnati, University of	Cincinnati
Cincinnati Bible College and Seminary	Cincinnati
Cincinnati College of Mortuary Science	Cincinnati
Cleveland College of Jewish Studies	Beachwood
Cleveland Institute of Art	Cleveland
Cleveland Institute of Music	Cleveland
Cleveland State University	Cleveland
Columbus College of Art and Design	Columbus
David N. Myers College	Cleveland
Dayton, University of	Dayton
Defiance College	Defiance
Denison University	Granville
DeVry Institute of Technology	Columbus
Findlay, University of	Findlay
Franciscan University of Steubenville	Steubenville
Franklin University	Columbus
Hebrew Union College—Jewish Institute of Religion	Cincinnati
Heidelberg College	Tiffin
Hiram College	Hiram
John Carroll University	Cleveland
Kent State University	*
Kenyon College	Gambier
Kettering College of Medical Arts	Kettering
Lake Erie College	Painesville
Lourdes College	Sylvania
Malone College	Canton
Marietta College	Marietta
Mercy College of Northwest Ohio	Toledo
Methodist Theological School in Ohio	Delaware
Miami University	†
Mount Carmel College of Nursing	Columbus
Mount St. Joseph, College of	Cincinnati
Mount Union College	Alliance
Mount Vernon Nazarene College	Mount Vernon
Muskingum College	New Concord
Northeastern Ohio Universities College of Medicine	Rootstown
Northwestern Ohio, University of	Lima
Notre Dame College	South Euclid
Oberlin College	Oberlin
Ohio, Medical College of	Toledo
Ohio College of Podiatric Medicine	Cleveland
Ohio Dominican College	Columbus
Ohio Northern University	Ada
Ohio State University	‡
Ohio University	§
Ohio Wesleyan University	Delaware
Otterbein College	Westerville
Pontifical College Josephinum	Columbus
Rio Grande, University of	Rio Grande
St. Mary Seminary and Graduate School of Theology	Wickliffe
Shawnee State University	Portsmouth
Tiffin University	Tiffin
Toledo, University of	Toledo
Trinity Lutheran Seminary	Columbus
Union Institute	Cincinnati
United Theological Seminary	Dayton
Urbana University	Urbana
Ursuline College	Cleveland
Walsh University	Canton
Wilberforce University	Wilberforce
Wilmington College	Wilmington
Winebrenner Theological Seminary	Findlay
Wittenberg University	Springfield
Wooster, College of	Wooster
Wright State University	Dayton
Xavier University	Cincinnati
Youngstown State University	Youngstown

*Campuses at Burton Township, Canton, Kent, and New Philadelphia.
†Campuses at Hamilton and Oxford.

Visitor's guide

Ohio has hundreds of historical, recreational, and scenic attractions. Historical points of interest include huge Indian burial mounds and forts that date back to prehistoric times.

The 2,500 lakes and 44,000 miles (70,800 kilometers) of rivers and streams in Ohio provide many opportunities for boating, fishing, and swimming. Lake Erie is a major tourist and recreational attraction. Hunters shoot deer, ducks, and rabbits in the state's woods and on the rolling plains. Many vacationers enjoy hiking in the hilly eastern section of Ohio, which has some of the state's most beautiful scenery.

Two historical plays performed outdoors rank among Ohio's most popular annual events. *Tecumseh*, a drama about the famous Shawnee Indian, is held near Chillicothe. *Trumpet in the Land*, which concerns Ohio's first permanent white settlement, is performed near New Philadelphia. Both plays run from June to September.

Great Serpent Mound near Hillsboro

Places to visit

Following are brief descriptions of some of Ohio's most interesting places to visit:

Adena State Memorial, in Chillicothe, is a restored stone house built in 1807 by Thomas Worthington, who later became governor of Ohio. It is furnished with rare American antiques of the 1700's and early 1800's.

Campus Martius Museum, in Marietta, stands on the site of the fortified stockade built by the first permanent white settlers in Ohio. The museum includes the home of Rufus Putnam, the founder of Marietta. The nearby Ohio River Museum exhibits models, pictures, and relics of riverboats.

Fort Recovery, in the village of Fort Recovery, is a reproduction of part of the fort that General Anthony Wayne built in 1793. General Wayne used the fort during the Indian wars in Ohio.

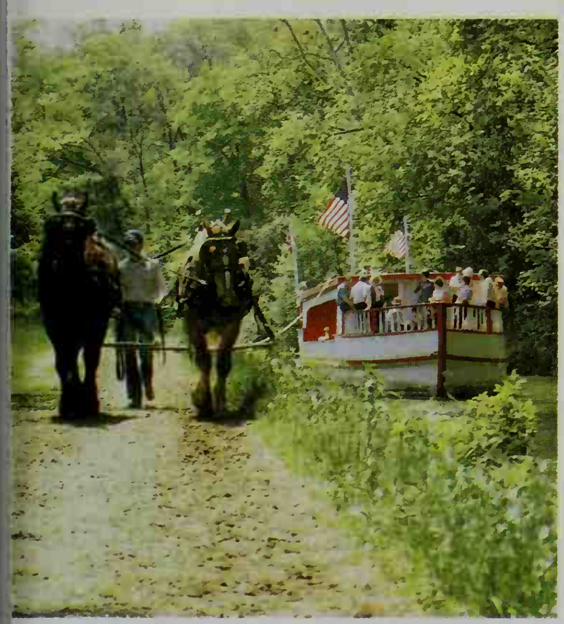
Indian mounds and other earthworks may be seen throughout the state. *Fort Ancient,* near Lebanon, is the largest hilltop earth structure in the United States. Its earthen walls, more than 20 feet (6 meters) high and 3 miles (5 kilometers) long, enclose over 100 acres (40 hectares). *Fort Hill,* near Bainbridge, is a 1,200-acre (486-hectare) area with a great walled enclosure on a high hill. *Great Serpent Mound,* near Hillsboro, is one of the best-known prehistoric structures in the world. The mound, shaped like a snake, has seven deep curves. It rises about 4 feet (1.2 meters) and extends over $\frac{1}{4}$ mile (0.4 kilometer). *Newark Earthworks,* at Newark, includes an octagonal earthen ridge that encloses about 50 acres (20 hectares), and circular earthen walls that enclose about 20 acres (8 hectares).

Kelleys Island, in Lake Erie near Sandusky, is a summer resort famous for its glacial markings and Inscription Rock. The markings—grooves cut into surface limestone by glaciers—are among the best examples of glacial action in the world. Inscription Rock is a large boulder with traces of prehistoric Indian carvings.

Pro Football Hall of Fame, in Canton, annually honors outstanding professional football players. It includes a museum of equipment that was worn by famous players and used in famous games.

Roscoe Village, in Coshocton, is a restored community that illustrates life on the Ohio and Erie Canal in the 1830's. It features homes, businesses, and a horse-drawn canal boat.

Rutherford B. Hayes Library and Museum, in Fremont, are at the former President's Spiegel Grove estate. The library has papers of Hayes and books on American life during the 1800's. The museum features exhibits on the life and times of Hayes and his family.



Schoenbrunn Village, near New Philadelphia, consists of reconstructed portions of the Moravian mission settlement founded there in 1772 for Indians. The site includes a replica of the first schoolhouse in what is now Ohio.

Wright-Patterson Air Force Base, near Dayton, is the nation's largest U.S. Air Force research field. The base includes the field on which the Wright brothers conducted their airplane experiments, and houses the world's largest military aviation museum.

Zoar Village, near New Philadelphia, was founded in 1817 by a group of Germans seeking freedom from religious persecution. The home of their leader, Joseph Bimeler, and the old Zoar Garden can be seen.

National forests and parklands. Wayne National Forest, the only national forest in Ohio, lies in the southeastern part of the state. Perry's Victory and International Peace Memorial stands at Put-in-Bay on South Bass Island in Lake Erie. It honors the American victory in the Battle of Lake Erie during the War of 1812, and a hundred years of peace between the United States and Canada. The granite shaft, 352 feet (107 meters) high, is one of the nation's tallest memorials. It has an observation deck at the top. Hopewell Culture National Historical Park, near Chillicothe, has many prehistoric Indian mounds. The Cuyahoga Valley National Recreation Area stretches along the Cuyahoga River between Akron and Cleveland. The William Howard Taft National Historic Site, in Cincinnati, includes the birthplace of the 27th President.

State parks and forests. Ohio has 72 state parks and 19 state forests. For information on the state parks of Ohio write to Chief, Division of Parks and Recreation, Fountain Square, Columbus, OH 43224.

Land and climate

Land regions. Several glaciers moved down from the north thousands of years ago, during the Ice Age. They covered all of what is now Ohio except the southeastern part. These separate glacial movements helped create the state's four main land regions. These four regions are (1) the Great Lakes Plains, (2) the Till Plains, (3) the Appalachian Plateau, and (4) the Bluegrass Region.

The Great Lakes Plains of northern Ohio form part of the fertile lowland that lies along much of the Great Lakes. In Ohio, these plains make up a narrow strip of land that borders Lake Erie. The region is 5 to 10 miles (8 to 16 kilometers) wide in the east, and broadens to more than 50 miles (80 kilometers) in the Maumee Valley to the west. A few low, sandy ridges along the Lake Erie shore break the flatness of the plains. A wide variety of crops, especially fruits and vegetables, grows in the region's fertile soil. The region is one of the busiest manufacturing, shipping, trading, and recreational areas in the United States. It includes many lake ports and large industrial cities. The most heavily populated part of Ohio, the Cleveland metropolitan area, is in the Great Lakes Plains region.

The Till Plains are the easternmost part of the rich midwestern Corn Belt, which stretches westward from Ohio. This region ranks among the most fertile farming areas in the country.

Some hills dot the gently rolling plains, which lie in most of western Ohio. One of them, Campbell Hill in Logan County, rises 1,550 feet (472 meters) and is the highest point in Ohio. From there, the land gradually slopes downward to the southwestern corner of the state in Hamilton County. This area, 433 feet (132 meters) above sea level, is Ohio's lowest point. Farmers of the Till Plains produce grain, soybeans, and livestock. The area has many industrial cities where a wide variety of products is manufactured. It also includes Columbus, the State Capital.

The Appalachian Plateau includes almost all the eastern half of Ohio. This highland extends eastward into Pennsylvania and West Virginia. The southern two-thirds of the region was not covered by glaciers. As a result, this section is the most rugged part of the state, with steep hills and valleys. Most of the soil is thin and not fertile. The northern third of the Appalachian Plateau has rolling hills and valleys, and has less fertile soil than that of the Till Plains.

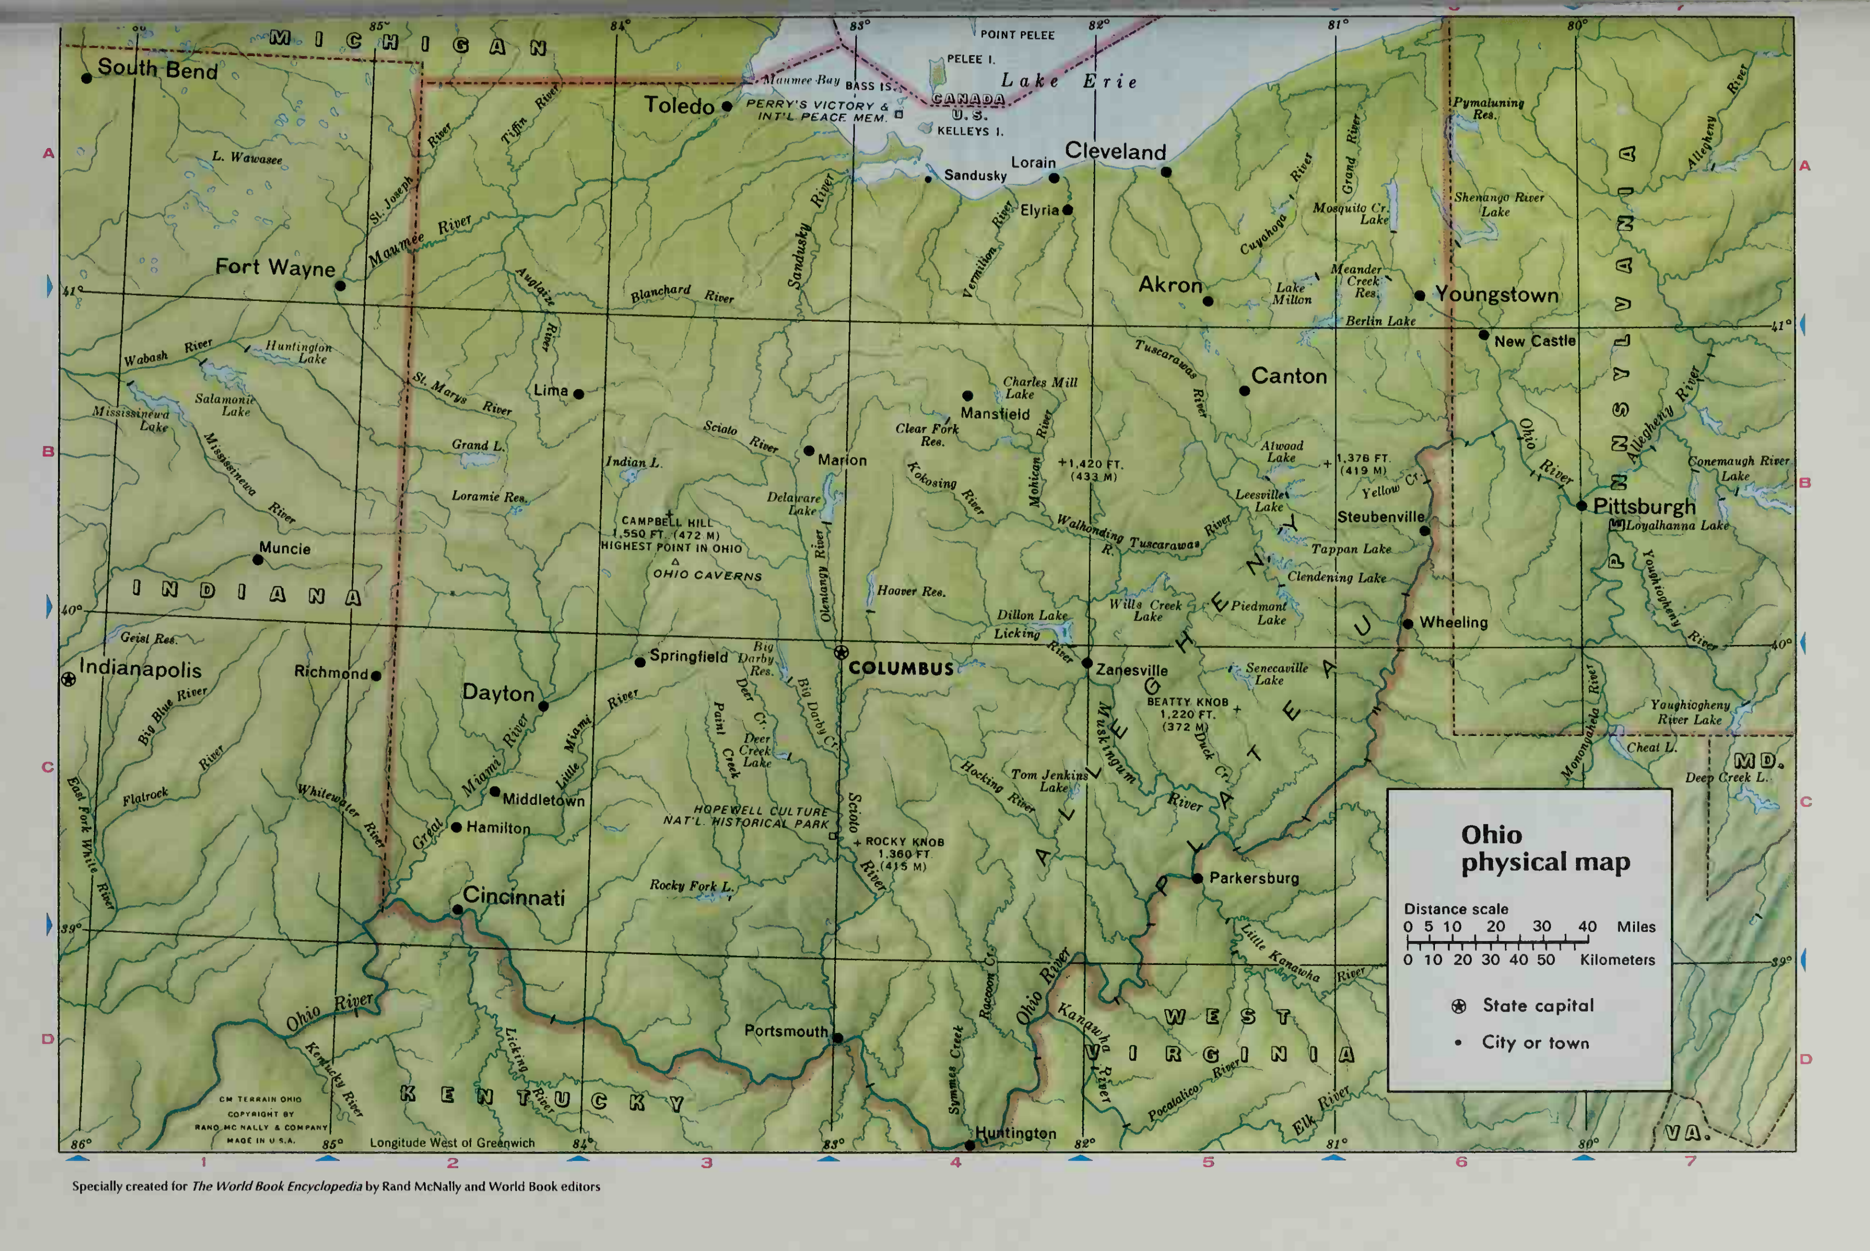
The rugged Appalachian Plateau has some of Ohio's most beautiful scenery, including the state's largest forests and some waterfalls. It also has Ohio's richest mineral deposits—clay, coal, natural gas, oil, and salt. A few of its cities are important manufacturing centers.

The Bluegrass Region, Ohio's smallest land region, is an extension of the Bluegrass Region of Kentucky. This triangular area in southern Ohio has both hilly and gently rolling land. The hills of the Bluegrass Region have thin, less fertile soil.

Shoreline of Ohio stretches for 312 miles (502 kilometers) along Lake Erie, from Conneaut in the east to Toledo in the west. It includes 53 miles (85 kilometers) along Sandusky Bay, and 66 miles (106 kilometers) along offshore islands. The eastern half of the shoreline consists of clay bluffs about 10 to 18 feet (3 to 5 meters) high. The western half has beaches of clay or sand. Many harbors indent the shoreline. Two of the busy lake ports lie on large bays—Toledo on Maumee Bay, and Sandusky on Sandusky Bay. North and northwest of Sandusky in Lake Erie are some small islands. The largest ones, Kelleys and North, Middle, and South Bass islands, are used chiefly as recreation areas.

Rivers and lakes. Ohio has more than 44,000 miles (70,800 kilometers) of rivers and streams. They flow either south into the Ohio River or north into Lake Erie. A series of low hills separates the two groups of rivers. This *divide* lies approximately along the southern boundary of the Great Lakes Plains and extends into Indiana. Except for the Maumee River, all the longer, wider rivers flow into the Ohio River. They drain about 70 percent of the state.

The Ohio River, one of the chief rivers of North America, flows more than 450 miles (724 kilometers) along Ohio's southern and southeastern borders. The northern bank of the river forms the state boundary. Many bluffs from 200 to 500 feet (61 to 150 meters) high rise along the river, which winds through a valley less than 2 miles (3 kilometers) wide.



The Ohio River's longest tributary in Ohio is the Scioto River, which is 237 miles (381 kilometers) long. Other rivers flowing into the Ohio include the Hocking,

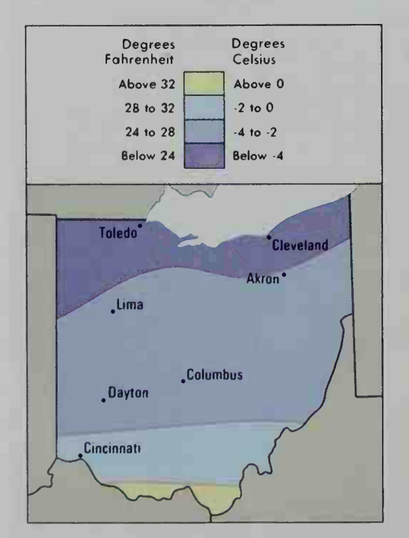
The Ohio River forms Ohio's southern border. Gallipolis, settled in the 1790's, overlooks West Virginia across the river.

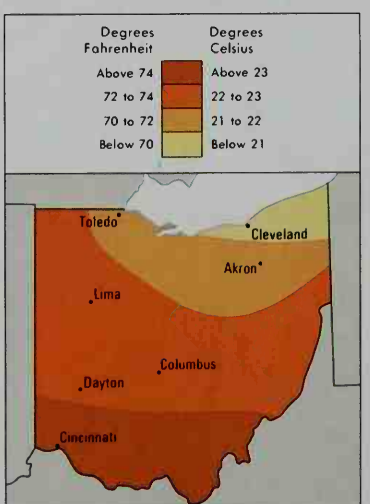
Irvin L. Oakes, Foto/Find



Little Miami, Great Miami, and Muskingum. The largest rivers that flow into Lake Erie are the Cuyahoga, Grand, Huron, Maumee, Portage, Sandusky, and Vermilion. Some underground streams in Ohio have formed caverns, such as Seven Caves near Bainbridge and Ohio Caverns near West Liberty. Many swift streams in northeastern Ohio have rapids and waterfalls.

Ohio's lake waters include 3,457 square miles (8,954 square kilometers) of Lake Erie. The International Line between the United States and Canada runs through Lake Erie about 20 miles (32 kilometers) north of the Ohio shore. The state has more than 2,500 lakes larger than 2 acres (0.8 hectare). Over 20 of them are natural lakes with an area of 40 acres (16 hectares) or more. These lakes were formed by the ancient glaciers. Ohio also has more than 180 artificially created lakes that cover at least 40 acres (16 hectares) each.

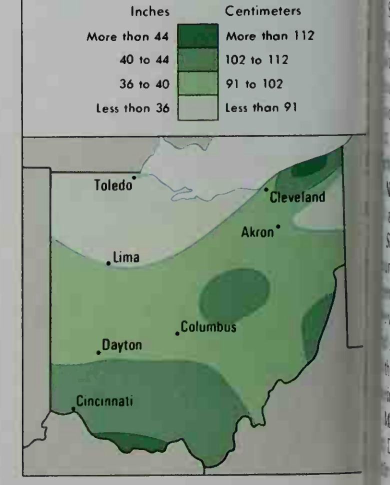
Several lakes were created in Ohio during the 1830's and 1840's to feed water into two canals. These canals were the Ohio and Erie Canal, between Cleveland and Portsmouth, and the Miami and Erie Canal, between Toledo and Cincinnati. They were Ohio's chief means of



Average January temperatures

Ohio has cold winters. Only the far southern section has temperatures that average above the freezing level.

Average July temperatures



The state has warm, humid summers. The south is the warmest and the areas along Lake Erie have the mildest summers.

Average yearly precipitation

The southern part of Ohio is the wettest, and the northwest is the driest. The northeast receives the heaviest snowfall.

transportation until the coming of the railroads in the 1840's. The largest lake in Ohio is 12,700-acre (5,140-hectare) Grand Lake near Indiana. It was created during the 1840's by damming two nearby creeks to provide water for the Miami and Erie Canal. Other large artificially created lakes include Berlin, Indian, Mosquito Creek, and Senecaville lakes.

Plant and animal life. Forests cover about a fourth of Ohio. Most of the state's trees are hardwoods. They include beeches, black walnuts, hickories, maples, sycamores, red and white oaks, tulip trees, white ashes, and white elms. Among the common shrubs found in Ohio are azalea, dogwood, hawthorn, sumac, and viburnum. The state's wildflowers include anemones, blazing stars, blue sages, Indian pipes, lilies, saxifrages, toothworts, and wild indigos.

Ohio has few large wild animals. Only white-tailed deer are plentiful. Smaller wild animals include minks, muskrats, opossums, rabbits, raccoons, red foxes, squirrels, skunks, and woodchucks. Among Ohio's songbirds are blackbirds, brown thrashers, cardinals, chickadees, and wrens. Bald eagles and various shore birds live along Lake Erie. Game birds include ducks, geese, pheasants, quail, and ruffed grouse. Fish living in the state's waters include bass, bluegills, catfish, muskellunge, perch, pike, and walleye.

Climate. Ohio has cold winters and warm, humid summers, with an average annual temperature of 52 °F (11 °C). The average January temperature is 28 °F (−2 °C), and the July temperature averages 73 °F (23 °C). Ohio's lowest recorded temperature, −39 °F (−39 °C), occurred at Milligan, near New Lexington, on Feb. 10, 1899. The highest recorded temperature was 113 °F (45 °C) near Gallipolis on July 21, 1934.

Ohio's annual *precipitation* (rain, melted snow, and other moisture) averages 38 inches (97 centimeters). The wettest area is in the southwest, where Wilmington's yearly precipitation is 44 inches (112 centimeters). The driest part of Ohio lies along Lake Erie between Sandusky and Toledo. It gets 32 inches (81 centimeters) of precipitation a year. Snowfall in Ohio averages 29 inches (74 centimeters) a year. It increases from west to east, and from south to north. Northeastern Ohio receives about 100 inches (254 centimeters) of snow annually and has several ski areas.

Economy

Located in the heart of the Rust Belt, the industrial region of the northeastern United States, Ohio has long been known as an important manufacturing center. Manufacturing is the single most important economic activity in Ohio. Its manufacturing industry is characterized by the wide variety of goods produced. The manufacture of aircraft parts, machine tools, motor vehicles, soap, steel, and plastics are all billion-dollar businesses in Ohio.

Service industries, taken together, account for the largest portion of Ohio's *gross state product*—the total value of goods and services produced annually. Community, business, and personal services are the state's leading service industry. Coal is the leading mined product. Soybeans and corn rank as Ohio's most valuable agricultural products.

Natural resources. Fertile soils and valuable minerals are Ohio's most important natural resources.

Soil. Fertile soils deposited by ancient glaciers are found in all parts of Ohio except the southeast. Many layers of these soils are several feet deep. Materials in the various kinds of soils include limestone, sandstone, and shale. The soil is less fertile in the southeastern part of the state, which was not covered by glaciers during the ice age.

Minerals. Coal is Ohio's most important mined product. Deposits in eastern and southeastern Ohio have an estimated 24 billion tons (22 billion metric tons) of coal. Oil and natural gas are found in several parts of Ohio. The state has about 100 million barrels of crude oil reserves. Ohio also contains huge reserves of rock salt and saltwater. The state could supply the United States with all the salt it needs for thousands of years. Most of the salt lies in deep rock-salt beds in northeastern Ohio. Other mined products in the state include large deposits of clay, gypsum, limestone and dolomite, sand and gravel, and sandstone.

Service industries, as a group, account for the largest portion of Ohio's gross state product and employ more people than any other type of industry. Most of the service industries are concentrated in the state's metropolitan areas.

Community, business, and personal services lead the service industries in terms of the gross state product. This group also employs more of Ohio's people than any other industry. Community, business, and personal services consist of a variety of businesses, including private health care, engineering firms, hotels, law firms, private research organizations, and repair shops. Cleveland is a leading center of health care in the United States. Columbus is the home of Battelle Memorial Institute, one of the world's largest private research organizations.

Wholesale and retail trade ranks second among service industries in contributions to the gross state product. The wholesale trade of coal, groceries, motor vehicles

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers Number of people	Percent of total
Manufacturing	25	1,122,800	17
Community, business, & personal services	18	1,963,300	30
Wholesale & retail trade	17	1,516,800	23
Finance, insurance, & real estate	16	474,600	7
Government	11	803,300	12
Transportation, communication, & utilities	8	288,100	4
Construction	4	346,600	5
Agriculture	1	158,600	2
Mining	†	22,500	†
Total	100	6,696,600	100

*GSP = gross state product, the total value of goods and services produced in a year.
†Less than one-half of 1 percent.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

and motor vehicle parts, and steel is important in Ohio. The ports of Toledo and Cincinnati handle much wholesale trade. Columbus is a leading distribution center for store merchandise. Retail businesses include department stores, food stores, and restaurants. The Cincinnati area is the home of several major U.S. retail companies, including Federated Department Stores and Kroger. Wendy's, a leading restaurant chain, is headquartered in Dublin. The Limited, a major retail clothing chain, is headquartered in Columbus.

Finance, insurance, and real estate ranks next among the service industries in terms of contribution to Ohio's gross state product. This industry group is most important in Cleveland and Columbus. Most of Ohio's largest banks are based in these cities, including Keycorp and National City of Cleveland. Cincinnati is also the home of several large financial companies. Several large insurance companies, including Nationwide and Progressive, have headquarters in Ohio. Real estate businesses have grown rapidly in the suburban parts of the large metropolitan areas.

Next among Ohio's service industries are government services, which include public schools and hospitals, and military bases. The public school system employs many people. Wright-Patterson Air Force Base lies near Dayton. State government offices are based in Columbus, which is also the home of Ohio State University.

Transportation, communication, and utilities rank fifth among Ohio's service industries in terms of contribution to the gross state product. Shipping is an important part of the transportation sector. Several large shipping companies lie along Lake Erie and the Ohio River. Roadway Express, a major trucking company, is headquartered in Akron. Telephone companies are the largest part of the communications sector. Ohio's largest utility companies are American Electric Power of Columbus and FirstEnergy of Akron. More information about transportation and communication appears later in this section.

Manufacturing contributes more to the gross state product than any other industry. Products made in the state have a *value added by manufacture* of about $120 billion a year. This figure represents the increase in value of raw materials after these materials become finished products. Ohio ranks high among the states in total value added by manufacture.

Transportation equipment is Ohio's leading manufactured product by far. The most important types of transportation equipment made in Ohio are motor vehicles, motor vehicle parts, and aircraft parts. Automobiles are assembled in East Liberty, Lordstown, and Marysville. The state's largest truck factories are in Avon Lake, Chillicothe, Lorain, Moraine, Springfield, and Toledo. Motor vehicle parts come mainly from Cleveland, Dayton, and Toledo. Large factories that produce aircraft parts are in Akron, Cleveland, and Evendale.

Fabricated metal products rank second among Ohio's manufactured products in terms of value added by manufacture. This category includes structural metal, metal stampings for automobiles, tools and hardware, and valves and pipe fittings. The Cleveland area leads the state in fabricated metal products.

Chemicals rank third in terms of value added by manufacture. Ohio's leading chemical products include soaps and cleansers, industrial chemicals, and paints and varnishes. The Procter & Gamble Company, a major manufacturer of soaps and cosmetics and many other products, is based in Cincinnati. Its soap factory in Cincinnati is the largest in the United States.

Primary metals rank fourth among Ohio's manufactured products. Indiana is the only state that produces more raw steel than Ohio. The largest centers of steel production are in the Canton, Cleveland, Lorain, Middletown, and Warren areas. Cincinnati and Cleveland have aluminum foundries.

Machinery is Ohio's fifth most valuable type of manufactured product in terms of value added by manufacture. The state's major machinery products are bearings, heating and cooling equipment, and machine tools and machine tool parts. Cincinnati, Cleveland, and Dayton are the chief centers of machine tool production in the state. Plants in Dayton make air-conditioning and ventilation equipment. Large factories in Canton manufacture ball and roller bearings.

Food products are Ohio's sixth-ranking manufactured product. The Cincinnati and Columbus areas are the state's main food processing centers. Cincinnati has meat packing plants. Factories in Columbus make beer and bakery products. Cooking oils are made in St. Bernard. Mariemont has a plant that makes cookies and crackers. Solon makes frozen dinners. Dairy products, which include pasteurized milk and cheese, are also important. The world's largest soup factory operates at Napoleon. A factory at Wellston is the world's leading producer of frozen pizzas.

Ohio is also an important manufacturer of rubber and plastic products, electrical equipment, computer and electronic equipment, clay and glass products, printed materials, and paper products. Factories in Akron, Dayton, and Findlay make such rubber products as hoses and tires. Goodyear Tire & Rubber, a major manufacturer of tires and other rubber products, has its headquarters in Akron. Many cities in Ohio produce plastic products. Types of electrical equipment manufactured in Ohio include appliances, electric motors, and lighting

equipment. Electronic equipment includes communication systems and scientific instruments. Clay products include bricks and tile, roofing, and tableware. Much pottery is manufactured along the Ohio River, especially in East Liverpool. Toledo and various other cities in Ohio are centers of the glassmaking industry. Plentiful deposits of sand and natural gas, which are used in glassmaking, helped establish the glassmaking industry in the state. Printed materials include newspapers and business forms. Many Ohio cities make paper products. Mead, a major manufacturer of paper and other wood products, is headquartered in Dayton.

Agriculture. Ohio has about 80,000 farms. Farms and ranches cover about half the state's land area.

Field crops provide most of Ohio's agricultural income. Soybeans are the state's leading farm product. Corn ranks second. Ohio ranks among the leading producers of both corn and soybeans. Farmers grow these two crops in nearly all parts of the state, especially in the Till Plains region. Other field crops raised in the state include hay, oats, popcorn, and wheat. Most of the grain production is used for livestock feed.

Milk is the leading livestock product in Ohio. Most of the milk produced in Ohio is sold in nearby cities. The state's leading dairy-farming areas include Wayne, Holmes, Columbiana, and Tuscarawas counties in the northeast, and Mercer County in the west.

Many farmers in Ohio raise beef cattle. Ohio also ranks as a major hog-producing state. Farmers in the Miami River Valley developed the famous Poland China hog during the 1800's. A monument to the Poland China breed stands near Monroe. Farmers also raise sheep for both mutton and wool, chiefly in the central part of the state. Ohio produces more wool than any other state east of the Mississippi River.

Ohio is one of the leading states in egg production. Most of the egg-producing poultry farms are located in the west-central and east-central parts of the state. Ohio poultry farmers also raise turkeys and *broilers* (chickens from 5 to 12 weeks old).

Ohio has been an important fruit-producing state since pioneer days, when Johnny Appleseed roamed the countryside planting apple seeds (see **Appleseed, Johnny**). In addition to apples, Ohio farmers produce grapes and strawberries. Grapes are raised on the plains along Lake Erie and on the offshore islands. The warm lake winds protect the grapes from frosts in late spring and early autumn. Some of the grapes are made into wine.

Large crops of cucumbers, sweet corn, and tomatoes are grown in Ohio. The rich soils of the Great Lakes Plains and the warmer lowlands located along the Ohio River are especially good for growing vegetables. During the cold season, vegetables are grown in heated glass shelters called *hothouses*. Other vegetables grown in Ohio include cabbage, celery, lettuce, peppers, and snap beans. The plains and lowlands in the state also have tree nurseries and flower greenhouses.

Mining. Coal is the greatest source of Ohio's mining income. The state's great fields of *bituminous* (soft) coal lie mainly in the east and southeast. Belmont, Meigs, Monroe, Morgan, and Vinton counties produce the most coal. The fields there form part of the great Appalachian coal fields that include parts of Pennsylvania and West Virginia.

Natural gas is the second most valuable mined product in Ohio. The southeastern part of the state is the leading area for natural gas production. Gas is pumped from the wells to businesses and homes, where it is used mainly for heating.

Economy of Ohio

This map shows the economic uses of land in Ohio and where the state's leading farm and mineral products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

Ohio leads all states in the production of building sandstone, providing about a third of the country's supply. Sandstone is taken chiefly from quarries in eastern and northern Ohio. The best-known variety of sandstone, Berea or *grit,* comes from Lorain County. Ohio's best clays come from the eastern part of the state, in or near the coal fields. These clays are used in such products as bricks and tile, cement, pottery, and stoneware.

Ohio provides about a fifth of all the limestone used in the United States to make glass. The state also leads in the production of lime, which is made from limestone. Other uses of limestone include the manufacture of cement, chemicals, fertilizers, and steel. Limestone is quarried chiefly in north-central Ohio.

Ohio's oldest mining industry is the production of salt, and the state is a leading salt producer. The deepest salt mine in the United States is near Fairport Harbor, northeast of Cleveland. The mine is about 2,000 feet (610 meters) deep. Petroleum is mined in several parts of eastern Ohio. Sand and gravel are produced throughout the state. Ohio's other mined products include abrasives, dolomite, and gypsum.

Electric power. Plants that burn coal provide about 85 percent of the electric power generated in Ohio. Air pollution from these plants is a major problem. Nuclear plants produce most of the remaining power.

Transportation. Ohio is a transportation link between the eastern and western United States. Cross-country railways and roads began going westward through the state during the 1800's.

The first east-west roads in Ohio were the natural trails that followed the sandy ridges along Lake Erie. Later roads, paved with logs, followed Indian trails. The historic Zane's Trace, built for the federal government by Ebenezer Zane, opened in 1797. It ran from what is now Wheeling, West Virginia, through the present-day Ohio cities of Zanesville, Lancaster, and Chillicothe to Maysville, Kentucky. Maysville was then the northern end of the road to New Orleans. During the early 1800's, the National (Cumberland) Road became an important link between the East and the West (see **National Road**).

Today, Ohio has about 115,000 miles (185,000 kilometers) of roads, most of which have hard surfaces. Many multilane highways and expressways cross the state. The 241-mile (388-kilometer) Ohio Turnpike runs from the Pennsylvania border across northern Ohio to Indiana. Four major railroad lines provide freight service in the state, and passenger trains serve about 10 cities.

Cleveland Hopkins International Airport is Ohio's busiest airport. Columbus, Dayton, and Toledo also have major airports. The largest airport serving the Cincinnati area lies in nearby Boone County, Kentucky.

The Great Lakes and the St. Lawrence Seaway connect Ohio with the Atlantic Ocean. Ice closes this passage in January and February. The Great Lakes also link Ohio with the north-central states and Canada. Another major waterway, the Ohio River, connects the state with the Mississippi River and the Gulf of Mexico. The entire length of this waterway is navigable all year.

Communication. The first newspaper published north and west of the Ohio River, the *Centinel of the North-Western Territory,* was founded in Cincinnati in 1793. The nation's first antislavery newspaper, the *Philanthropist,* began publication in Mount Pleasant in 1817. Today, the state has about 80 daily newspapers and 250 weeklies. The largest daily newspapers include the Akron *Beacon Journal, The Blade* of Toledo, *The Cincinnati Enquirer, The Cincinnati Post, The Columbus Dispatch, Dayton Daily News,* and *Plain Dealer* of Cleveland. About 370 periodicals are published in Ohio.

Ohio's oldest radio station, WHK, began broadcasting in Cleveland in 1922. Also in 1922, Ohio State University in Columbus started WOSU, the first educational radio station in North America. The first Ohio TV station, WEWS-TV, opened in Cleveland in 1947. Today, Ohio has about 310 radio stations and about 45 TV stations. Cable television systems and Internet providers serve communities statewide.

Government

Constitution of Ohio, the second in the state's history, was adopted in 1851. Ohioans adopted their first constitution in 1802. An amendment may be proposed by (1) the state legislature, (2) a petition signed by 10 percent of the voters, or (3) a constitutional convention. A convention may be called if it is approved by two-thirds of each house of the legislature and by a majority of the voters. Ohioans also vote every 20 years as to whether they wish to call a constitutional convention. Amendments to the Constitution must be approved by a majority of the people voting on them in an election.

Executive. The governor of Ohio is elected to a four-year term. He or she can serve an unlimited number of terms, but not more than two terms in succession. The governor has the power to appoint the heads of many of the state's administrative departments and agencies and also the trustees of state-supported universities and institutions. The appointments of the governor must be approved by the state Senate.

Voters elect the lieutenant governor, secretary of state, attorney general, treasurer, and auditor. These officials may not serve more than two terms in succession.

Legislature, called the *General Assembly,* consists of a 33-member Senate and a 99-member House of Representatives. Voters in each of Ohio's 33 senatorial districts elect one senator. Senators serve four-year terms and may not serve more than two terms in succession. Voters in each of the state's 99 representative districts elect one representative. Representatives serve two-year terms and may not serve more than four terms in succession. Regular legislative sessions begin on the first Monday of January in odd-numbered years and have no time limit.

A 1903 amendment to the state Constitution required that each county have at least one representative, regardless of its population. In 1964, the Supreme Court of the United States ruled this amendment unconstitutional. In 1965, Ohio's governor, the state auditor, and the secretary of state drew up a *reapportionment* (redivision) plan for the Senate and House of Representatives. They set up single-member legislative districts that were as equal in population as possible. A special three-judge

*Democratic-Republican

federal district court approved the plan for use until a permanent plan could be drawn. The Supreme Court of the United States approved the federal district court's decision. In 1967, the Constitution was amended to provide for a permanent reapportionment plan.

Courts. The highest appeals court in Ohio is the Supreme Court. It has a chief justice and six other justices—all elected to six-year terms. Ohio also has 12 courts of appeals. The court of Cuyahoga County has 12 judges. The other districts in Ohio have from 3 to 8 judges each. The highest trial courts in Ohio are the courts of common pleas. Each of the state's 88 counties has one such court. These courts have varying numbers of judges, all of whom are elected to six-year terms. Other courts in Ohio include county, juvenile, municipal, mayor, and probate courts.

Local government. Ohio has 88 counties. All of the counties except Summit are governed by an elected three-member board of commissioners. Summit County is governed by an elected county executive and a seven-member council. By law, counties may have *home rule*—that is, a county may adopt its own charter. But only Summit County has done so.

Ohio law defines cities as incorporated communities with at least 5,000 people. Villages have populations of less than 5,000. Officially, Ohio has no towns. Ohio law allows cities and villages to adopt home rule, and about a fourth of them have done so. The home-rule cities and villages have mayor-council, council-manager, or commission governments. In 1913, Dayton became the nation's first large city to adopt council-manager government. About three-fourths of Ohio's cities and villages have a mayor-council government.

Revenue. Taxes account for more than half of the state government's *general revenue* (income). Most of the rest comes from federal grants and other U.S. government programs. A general sales tax and a personal income tax are the leading sources of tax revenue. Other state taxes include those on motor fuels, corporate income, public utilities, and motor vehicle licenses. Other revenue comes from charges for government services and from a state lottery.

Politics. Both the Democratic and Republican parties have much strength in Ohio. The Democratic Party is strongest in Cleveland and other metropolitan areas in northeastern Ohio. The Republican Party is dominant in most rural areas and is also strong in the Cincinnati and Columbus metropolitan areas. Since the end of World War II in 1945, Democratic and Republican candidates have won elections for governor about an equal number of times.

Ohio is often called a *barometer state* in national politics. That is, the political views of Ohioans frequently indicate those of most Americans. For example, the winning presidential candidates have won Ohio's electoral votes in a great majority of presidential elections since 1804. For Ohio's electoral votes and its voting record in presidential elections, see **Electoral College** (table).

History

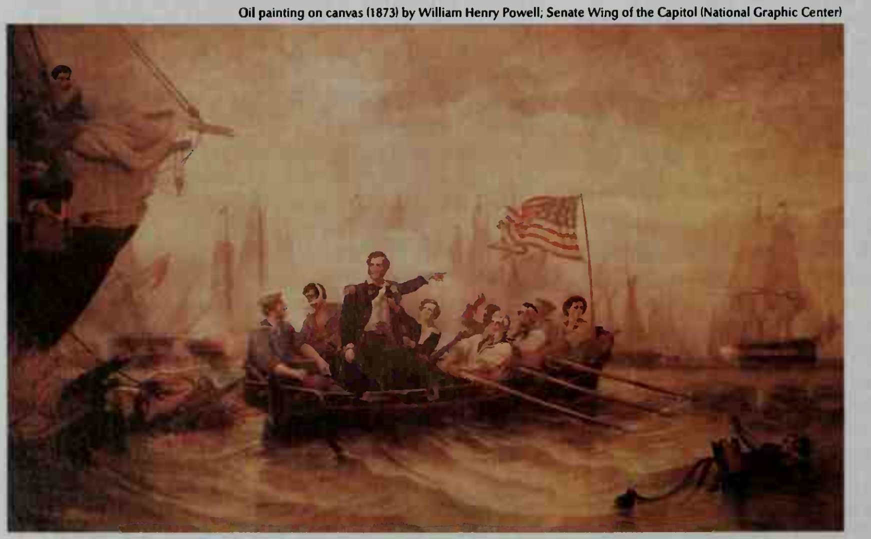
Indian days. Thousands of years ago, prehistoric Indians lived in what is now Ohio. These Indians were the ancestors of peoples called *Mound Builders,* some of whom had high forms of civilization. The Mound Builders left more than 6,000 burial mounds, forts, and other earthworks throughout the Ohio region. The Indians included the Adena and Hopewell peoples, who lived there from about 600 B.C. to about A.D. 500. See **Mound Builders.**

When the early white settlers arrived, several Indian tribes lived in the Ohio region. These tribes included the Delaware, Miami, Shawnee, and Wyandot, or Huron.

Exploration and settlement. The French explorer René-Robert Cavelier, Sieur de La Salle, was probably the first white person to reach present-day Ohio. He is believed to have visited the region about 1670. The French based their claim to the entire Northwest on La Salle's explorations. But the British claimed all the territory extending inland from their Atlantic colonies. In 1750, the Ohio Company of Virginia sent Christopher Gist to explore the upper Ohio River Valley. This company, organized in 1747, was made up of English people and Virginians who planned to colonize the Ohio region. See **Gist, Christopher; La Salle, Sieur de; Ohio Company** (The first Ohio Company).

The dispute between Britain and France over territory in North America, including the Ohio region, led to the French and Indian War (1754-1763). In the peace treaty of 1763, France gave Britain most of its lands east of the Mississippi River. Pontiac, an Indian chief believed to have been born in Ohio, started an Indian rebellion against the British in 1763 after the peace treaty was signed. See **French and Indian wars; Pontiac.**

Fighting during the Revolutionary War in America (1775-1783) forced a Moravian mission settlement named Schoenbrunn, near present-day New Philadelphia, to close down. The settlement, founded in 1772 by David Zeisberger, was abandoned in 1776. In 1780, George Rogers Clark defeated Shawnee Indian allies of the British in the Battle of Piqua, near present-day Springfield. Clark's campaigns in the Northwest helped win the region for the United States during the Revolutionary War.

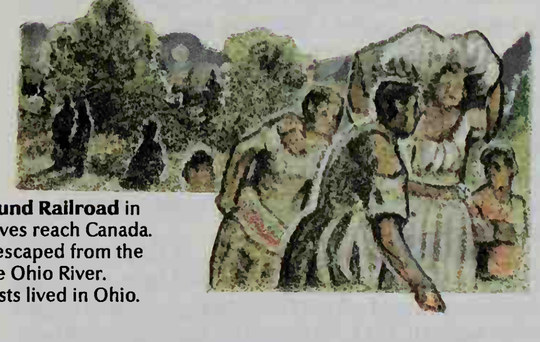


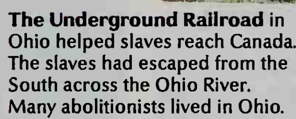
The region, including Ohio, became the Northwest Territory in 1787. The Northwest Ordinance of 1787 provided for the eventual statehood of Ohio and other divisions of the territory. That year, the Ohio Company of Associates bought land northwest of the Ohio River in the Muskingum River Valley. Members of this company came from New England. On April 7, 1788, the company founded Marietta, the first permanent white settlement in Ohio. Rufus Putnam, a Revolutionary War general, was superintendent of the colony. Marietta became the first capital of the Northwest Territory in July 1788. Soon other communities developed along the Ohio River. Many settlers were Revolutionary War veterans who received land in payment for their military service. See **Northwest Territory; Ohio Company** (The second Ohio Company); **Putnam, Rufus.**

For several years, Indian uprisings disturbed the settlers. Several raids were led by Little Turtle, a Miami chief. In 1794, General Anthony Wayne defeated the Indians near present-day Toledo in the Battle of Fallen Timbers. The next year, in the Treaty of Greenville, the Indians ceded the United States about two-thirds of what is now Ohio. The Indians accepted the treaty largely through the influence of Tarhe, or Crane, a Wyandot chief. With peace restored, more and more settlers poured into the region. Many settlements were founded in the valleys of rivers flowing into the Ohio. Some pioneers also settled in northeastern Ohio in the area called the Western Reserve (see **Western Reserve**).

In 1800, Congress passed the Division Act. This legislation created the Indiana Territory out of the western part of the Northwest Territory. Chillicothe became the capital of the eastern part, which continued to be called the Northwest Territory.

Statehood. Preparation for Ohio statehood began in November, 1802, when a convention in Chillicothe drew up the state's first constitution. Ohio became the 17th state on March 1, 1803, when the first state legislature met. Edward Tiffin, a Democratic-Republican, was the





Oil painting on canvas (1873) by William Henry Powell; Senate Wing of the Capitol (National Graphic Center)

Commodore Oliver H. Perry defeated the British in the Battle of Lake Erie during the War of 1812. While the battle raged, he rowed from a disabled ship, the *Lawrence,* to take command on the undamaged *Niagara.*

Historic Ohio

The Underground Railroad in Ohio helped slaves reach Canada. The slaves had escaped from the South across the Ohio River. Many abolitionists lived in Ohio.

Oberlin College, established in 1833, was the first coeducational college in the United States.

B. F. Goodrich began making rubber products in Akron in 1870. Akron became a major tire manufacturer after *pneumatic tires* (tires filled with compressed air) were first used on automobiles in 1895.

The Cincinnati Red Stockings (now the Reds) became the first professional baseball team in 1869.

The Wright Brothers built the first wind tunnel in North America in Dayton in 1901. They used it to conduct experiments that led to the first successful airplane flight.

Important dates in Ohio

c. 1670 The French explorer René-Robert Cavelier, Sieur de La Salle, probably was the first white man to reach the Ohio region.

1747 The Ohio Company of Virginia was organized to colonize the Ohio River Valley.

1763 France surrendered its claim to the Ohio region to Britain.

1787 The Northwest Territory was established.

1788 The first permanent white settlement in Ohio was established in Marietta.

1795 Indian wars in the Ohio region ended with the Treaty of Greenville.

1800 The Division Act divided the Northwest Territory into two parts, and Chillicothe became the capital of the new Northwest Territory.

1803 Ohio became the 17th state on March 1.

1813 Commodore Oliver H. Perry's fleet defeated the British in the Battle of Lake Erie.

1832 The Ohio and Erie Canal was completed.

1836 The Ohio-Michigan boundary dispute was settled.

1845 The Miami and Erie Canal was completed.

1870 Benjamin F. Goodrich began the manufacture of rubber goods in Akron.

1914 Ohio passed the Conservancy Act after floods in 1913.

1922 The Miami River Valley flood-control project was finished.

1938 The flood-control project in the Muskingum River Valley was completed.

1955 The Ohio Turnpike was opened to traffic.

1959 Terms of the governor and other high state officials were increased from two years to four.

1967 Ohio voters approved a plan for reapportionment of the state legislature.

1971 Ohio adopted an income tax.

1993 Ohio voters approved the sale of $200 million worth of bonds to finance improvements and expansion in the state's parks and other recreation areas.

first governor. Ohio's population was about 70,000. Chillicothe was the capital from 1803 to 1810, when Zanesville became the capital. Chillicothe again became the capital in 1812, and Columbus in 1816.

The Louisiana Purchase in 1803 gave Ohio settlers a river outlet for their products. They could ship goods down the Mississippi River and through the port of New Orleans. A thriving river trade with New Orleans soon developed. The first steamboat to travel the Ohio River was the *New Orleans,* a wood-burning side-wheeler. It first went down the river in 1811.

Ohio took an active part in the War of 1812 (1812-1815). Commodore Oliver H. Perry sailed from Put-in-Bay at South Bass Island off the Ohio shore to battle a British fleet on Sept. 10, 1813. Perry won an important naval victory in this Battle of Lake Erie (see **Perry, Oliver H.**). After the war, thousands of people moved to Ohio from the eastern states. Many came from New England, New York, and Pennsylvania. Immigrants arrived from Britain and Germany.

In 1818, the steamboat *Walk-in-the-Water* became the first steamboat on Lake Erie. It demonstrated the practical use of the Great Lakes as a waterway to the West. The Erie Canal across New York from Lake Erie opened in 1825. The Ohio and Erie Canal, joining Cleveland and Portsmouth, was completed in 1832. The Miami and Erie Canal, connecting Toledo and Cincinnati, was completed in 1845. These canals served as busy trade routes for more than 25 years. But the coming of the railroads reduced canal traffic. Ohio canals and railroads brought increased prosperity, and many mills and factories were built between 1830 and 1860.

An old border dispute between Ohio and the Territory of Michigan flared up in 1835 and led to the "Toledo War." Before any actual fighting broke out, President Andrew Jackson sent agents to Toledo to persuade the governors of Ohio and Michigan to accept a truce. In 1836, Congress awarded the disputed area, about 520 square miles (1,350 square kilometers) along Lake Erie, to Ohio. In 1841, William Henry Harrison of North Bend became the ninth President.

The Civil War. During the years before the Civil War (1861-1865), many Ohioans had strong feelings on the question of slavery. Many *abolitionists* (people opposed to slavery) lived throughout Ohio. They helped slaves who had escaped across the Ohio River on their flight to Canada (see **Underground Railroad**). Most of Ohio's Southern sympathizers lived in the southern and north-central parts of the state. In 1862, Clement L. Vallandigham of Dayton became leader of the Peace Democrats Party, which opposed President Abraham Lincoln's Administration. Vallandigham and other Southern sympathizers were known as Copperheads.

Many famous Civil War commanders were born in Ohio, including Ulysses S. Grant and William T. Sherman. Ohio supplied about 345,000 men to the Union army. This was more than the total quotas requested by 10 presidential calls for soldiers from the state. In 1863, Confederate cavalrymen known as Morgan's Raiders crossed into Ohio and brought Civil War fighting to its northernmost point. Led by General John Hunt Morgan, they were captured in Columbiana County. Morgan later escaped and returned to the South. See **Morgan, John Hunt**.

Ohio Historical Society
Floodwaters caused enormous destruction in the Miami River Valley during the spring of 1913. Floods killed about 350 people.

Ohio's industrial centers grew rapidly after the Civil War. Many workers from other countries settled in the state. The shipping of coal, iron ore, and other bulk goods on Lake Erie increased. Farming continued to be a leading industry, but Ohio also developed into a top manufacturing state. In 1869, the Cincinnati Red Stockings (now Reds) became the first all-professional baseball team. Benjamin F. Goodrich began manufacturing rubber products in Akron in 1870.

Five Ohio-born Presidents, all Republicans, were elected during the 1800's. They were Ulysses S. Grant, Rutherford B. Hayes, James A. Garfield, Benjamin Harrison, and William McKinley. President William Henry Harrison of Ohio was born in Virginia.

The early 1900's. Ohio's government was torn by scandal and corruption during the late 1800's. Marcus A. "Mark" Hanna, political boss of Cleveland, and George B. Cox, boss of Cincinnati, both Republicans, controlled state politics. Reform movements began about 1900, and promoted honesty and efficiency in city and state governments. William Howard Taft of Cincinnati became the 27th President of the United States in 1909.

Ohio suffered the worst floods in its history during the spring of 1913. About 350 people lost their lives after rivers overflowed their banks, and damage totaled about $100 million. Most of the destruction occurred in the Miami River Valley, especially at Dayton. In 1914, the state legislature passed the Conservancy Act, the first legislation of its kind in the United States. The chief purpose of the act was to permit the establishment of flood-control districts based on entire river systems. Many flood-control dams and reservoirs were built under the Conservancy Act, including those completed by 1922 in the Miami River Valley. The federal government also built about 20 flood-control dams in Ohio.

After the United States entered World War I in 1917, the state produced vast supplies of war materials. Newton D. Baker of Cleveland served as secretary of war in President Woodrow Wilson's wartime Cabinet.

Between world wars. In 1921, Warren G. Harding of Marion became the 29th President. His Democratic opponent was Governor James M. Cox of Dayton. The 1920's were prosperous years in Ohio, because of continued industrial development. Cincinnati, Cleveland, Dayton, Toledo, and other industrial cities expanded rapidly. Many nearby farms disappeared as the cities grew. The Great Depression that began in 1929 hit these cities hardest in Ohio. Thousands of workers lost their jobs as factories closed. Many farmers lost their land when farm prices dropped sharply.

Government funds and federal agencies such as the Works Progress Administration (WPA), later called Work Projects Administration, helped Ohio recover from the depression during the 1930's. In 1934, work began on the Muskingum River Valley flood-control project. This project came to national attention in 1937, when most of the dams withstood heavy floodwaters of the Ohio River. It was completed in 1938. Robert A. Taft, who became one of the most powerful U.S. senators, began his first term as Republican senator from Ohio in 1939.

The mid-1900's. During World War II (1939-1945), Ohio produced aircraft, ships, and weapons. It also contributed steel, tires, and materials to the war effort. The armed services established a number of training centers in the state. During the 1950's, the Atomic Energy Commission (AEC) built several installations in Ohio. They included the Portsmouth Area Project in Pike County, which produces uranium-235 for use in nuclear reactors. In 1955, the 241-mile (388-kilometer) Ohio Turnpike across northern Ohio opened. Since 1958, the National Aeronautics and Space Administration (NASA) has operated the John H. Glenn Research Center at Lewis Field in Cleveland. Scientists there conduct research on space propulsion systems.

Ohio's industrial growth moved forward rapidly during the 1960's. In 1963, the state launched a giant economic development program to attract more industry. Industrial expansion included new aluminum plants and chemical factories in cities in a region along the Ohio River that offered cheap, coal-generated power.

Center for Lake Erie Area Research, Ohio State University

Scientists check water quality from a research vessel in Lake Erie by measuring the quantity and types of microscopic animals called *zooplankton* in the water.

Ohio also entered international trade. Eight Ohio cities on Lake Erie—Ashtabula, Cleveland, Conneaut, Fairport, Huron, Lorain, Sandusky, and Toledo—became ports of the St. Lawrence Seaway, which opened in 1959. By 1970, Ohio ranked fourth among the states in the value of goods exported annually.

Several significant changes occurred in state government. In 1959, Ohio voters increased the terms of the governor and other elected executive officials from two to four years. The Supreme Court of the United States ruled in 1964 that Ohio must *reapportion* (redivide) its House of Representatives to provide more equal representation based on population. The state legislature drew up a reapportionment plan for both the House and Senate, which the voters approved in 1967.

Recent developments. The state legislature enacted an income tax in 1971 to help pay for the rising costs of state government. In 1972, voters approved an amendment to the state constitution permitting a state lottery to help fund public schools.

Ohio has now recovered from many of its most troubling problems of the late 1960's and 1970's. Between 1966 and the mid-1970's, several school districts closed their public schools because of a lack of funds. Today, state laws require local school districts to borrow funds from the state government if necessary in order to meet educational expenses. Also, state income taxes were increased during the early 1980's to help provide funding for public schools and the state-supported university system, and to support other state public services.

Ohio has also had to deal with problems caused by decreasing energy resources. Fuel shortages during the mid-1970's caused an increase in fuel prices and a decrease in production. During a severe winter in 1977, a shortage of natural gas forced many of the state's factories, offices, and schools to close temporarily.

In the mid-1980's, however, abundant natural gas and cheaper petroleum gave a boost to many of Ohio's important manufacturing industries, including the production of automobiles and chemicals. In 1985, Ohio voters approved a $100 million bond issue to finance research on ways to develop technologies to reduce the high-sulfur content of the state's coal. The goal was to make the coal meet environmental standards, thus increasing its use. An electric power plant using low-sulfur coal that resulted from the research opened in 1993.

Another serious problem for Ohio has been the pollution of Lake Erie and the state's rivers. Federal and state antipollution laws and controls have now cleaned up state rivers and Lake Erie for both commercial fishing and recreation. In 1993, Ohio voters approved a $200 million bond issue to finance improvements and expansion in the state's parks and other recreation areas.

Nevertheless, Ohio continues to have serious problems. Ohio manufacturers—especially the steel industry—face increasing foreign competition. Some of Ohio's industries have moved to states with warmer climates and cheaper labor. Many Ohio farmers have also had difficulties. Periodic declines in prices for crops and livestock result in lower incomes for farmers. Many smaller farmers have been forced out of business by such slumps.

Questions

How many United States presidents came from Ohio? Which one of these men was not born in Ohio?
How did Ohio pioneer in flood-control legislation?
What is Ohio's most valuable farm activity?
Why is Ohio called a *barometer state* in politics?
What was the first United States college for both men and women?
What was the "Toledo War"? What was the result of this border dispute?
What Ohio educator became famous as an author of reading books for schoolchildren?
What was the first educational radio station in North America? When and where was it established?
What is the single most important economic activity that operates in the state?
Which service industry employs the greatest number of people in Ohio?

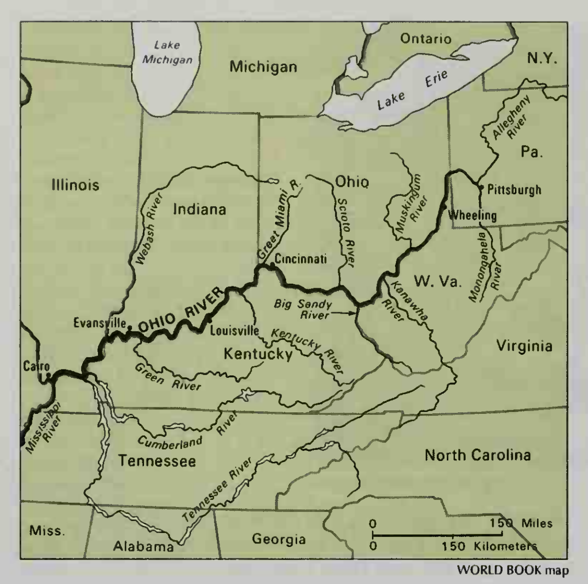
Pioneers in Ohio settled in the Northwest Territory as a result of the forming of the second Ohio Company in 1786.

Ohio Company. There were two Ohio Companies in American history. The purpose of each was to colonize the Ohio River Valley.

The first Ohio Company was formed in 1747. It is sometimes called the Ohio Company of Virginia. Its members included London merchants and wealthy Virginians. Among them were George Washington's brothers, Lawrence and Augustine Washington. In 1749, King George II granted the company 200,000 acres (81,000 hectares) west of the Allegheny Mountains in Maryland, Pennsylvania, and Virginia, and on both sides of the Ohio River. The company surveyed the Ohio River Valley. It traded with Indians, built storehouses and roads, and established the first fort at the forks of the Ohio. In 1753, a settlement called *Gist's Plantation* was founded near Mount Braddock, Pa. The French destroyed the company's strongholds in 1754. The French and Indian War (1754-1763) blocked efforts to settle in the west. The company went out of business in 1792.

The second Ohio Company was the more important. Its official name was the Ohio Company of Associates. It was organized at the Bunch of Grapes Tavern in Boston on March 1, 1786. Eleven delegates, elected by persons interested in the venture, set up the company. They planned to raise $1 million in $1,000 shares, which was payable in almost worthless Continental paper money. Within a year the company distributed 250 shares. The company appointed Manasseh Cutler, Rufus Putnam, and Samuel Parsons to petition the Congress of the Confederation to sell it a tract beyond the Ohio River. Congress approved, and later passed the Northwest Ordinance of 1787 (see **Northwest Ordinance**).

At first the Ohio Company contracted to buy $1\frac{1}{2}$ million acres (610,000 hectares) at $66\frac{2}{3}$ cents an acre. But because of financial difficulties, these terms were never fully carried out. Congress finally granted title to 750,000 acres (304,000 hectares) in what is now southeastern Ohio. The agreement provided that 214,285 acres (86,718 hectares) could be bought with army warrants, and that 100,000 acres (40,000 hectares) were to be offered free to settlers. One section of each township was reserved for schools, one for religion, and three sections for future disposal by Congress. This last term was designed to keep speculators from monopolizing the territory. Two townships of 46,080 acres (18,648 hectares) were set aside "for the support of an institution of higher learning." This institution was founded at Athens, Ohio, in 1804, and became Ohio University.



The Ohio Company appointed Rufus Putnam as its superintendent. He led an advance party of 47 surveyors, carpenters, boatbuilders, blacksmiths, and laborers to lay out a town where the Muskingum and Ohio rivers joined. The group arrived at the mouth of the Muskingum on April 7, 1788. It founded there the first settlement under the Northwest Ordinance, and named it *Marietta* in honor of Queen Marie Antoinette of France. The settlers also built a fort called *Campus Martius* to protect their village. On July 15, Governor Arthur St. Clair established the first capital of the Northwest Territory at Marietta. By April, 1789, three new settlements had been established. The Ohio Company completed its land operations by 1797. It divided its assets among the shareholders, but did not go out of business until about 1832. Richard J. Hopkins

Ohio River is the second most heavily used commercial river in the United States. Only the Mississippi River has more cargo shipped on it. The Ohio flows 981 miles (1,579 kilometers) through some of the nation's busiest industrial regions and richest farmlands. About 203 million short tons (184 million metric tons) of freight are transported annually on the Ohio. The river serves some of the country's principal coal fields and several major steel-producing districts. It drains an area of about 204,000 square miles (528,400 square kilometers).

The Ohio River begins in Pittsburgh, Pa., where the Allegheny and Monongahela rivers meet. The Ohio flows mainly southwestward and forms the southern borders of Ohio, Indiana, and Illinois, and the northern boundaries of West Virginia and Kentucky. It empties into the Mississippi River at Cairo, Ill. Major branches of the Ohio include the Muskingum, Kanawha, Big Sandy, Scioto, Licking, Great Miami, Kentucky, Green, Wabash, Cumberland, and Tennessee rivers.

Navigation. Almost all the cargo transported on the Ohio River moves on large barges. These barges are pushed by tugboats. Dams and canals provide a minimum water depth of 9 feet (2.7 meters). Locks in the canals raise and lower the water level in the river, en-

Location of the Ohio River

abling ships to travel the entire length of the Ohio River.

Coal makes up almost half the total freight shipped on the Ohio. Other major cargoes include agricultural products, chemicals, crushed rock, gravel, petroleum products, sand, and steel products. Among the chief ports along the Ohio are Pittsburgh and Aliquippa, Pa.; Huntington, W. Va.; Cincinnati, Ohio; Louisville, Ky.; and Mount Vernon, Ind.

Animal and plant life. Forests of beech, hickory, oak, poplar, and sycamore trees cover the Ohio River Valley. Animals in these forests include chipmunks, muskrats, raccoons, red foxes, squirrels, white-tailed deer, and woodchucks. Among the fishes in the Ohio are bullheads, bass, catfish, and trout.

Community and industrial wastes and farming chemicals pollute the Ohio. Pollution threatens fish and other wildlife. The Ohio River Valley Water Sanitation Commission regulates the release of river pollutants.

History. In 1669, the French explorer René-Robert Cavelier, Sieur de La Salle, became the first European to see the Ohio River. At that time, Shawnee and other Indians lived along its shores. Throughout the 1700's, traders used the river to explore the entire Ohio River Valley. Settlers traveled on the Ohio to the Northwest Territory after that region was established in 1787.

More than 60 steamboats were active on the Ohio by 1820. After the Civil War ended in 1865, the river became a major corridor for the shipment of raw materials and industrial products. During the early 1900's, the steamboats were gradually replaced by powerful tugboats pushing heavy barges.

Flooding along the Ohio often causes heavy damage. Severe floods in 1937, 1945, and 1963 brought great losses of life and property. Since the 1950's, the federal government has worked with the states bordering the river to build 19 dam-canal structures that control most flooding on the Ohio. John Edwin Coffman

Ohio State University is a state-assisted coeducational institution with campuses in Columbus, Lima, Mansfield, Marion, and Newark, Ohio. The main campus is in Columbus. The university also operates two facilities in Wooster, Ohio—the Agricultural Technical Institute, a two-year college; and the Ohio Agricultural Research and Development Center.

The Columbus campus has colleges of agriculture, the arts, biological sciences, business, dentistry, education, engineering, human ecology, humanities, law, mathematical and physical sciences, medicine, nursing, optometry, pharmacy, social and behavioral sciences, social work, and veterinary medicine. It grants bachelor's, master's, and doctor's degrees. The campuses at Lima, Mansfield, Marion, and Newark offer liberal arts programs leading to associate of arts and bachelor's degrees.

The university operates its own radio and television stations and has an airport near the Columbus campus. The university's Franz Theodore Stone Laboratory, located in Put-in-Bay, Ohio, studies the biology of the Great Lakes.

Ohio State University was founded in 1870 as a land-grant college. Originally called Ohio Agricultural and Mechanical College, the school opened in 1873. It took its present name in 1878. The other campuses were founded between 1957 and 1960.

Critically reviewed by the Ohio State University

Ohio University is a state-assisted coeducational school in Athens, Ohio. The university has nine colleges that grant undergraduate degrees—University College; the honors-tutorial college; and the colleges of arts and sciences, business administration, communication, education, engineering and technology, fine arts, and health and human services. University College offers associate degrees and a bachelor's degree in general studies. The honors-tutorial college has special programs for gifted or highly motivated students.

Ohio University also offers master's and doctor's degrees. It maintains five regional campuses and an academic center in southeastern Ohio. The university also has a lifelong learning division.

Ohio University was founded in 1804. It was the first institution of higher learning in the vast Midwestern region called the Northwest Territory.

Ohm is the unit used to measure resistance to the passage of an electric current. All materials resist the flow of electric current. But some materials offer more resistance than others. Materials that offer little resistance are called *conductors.* Materials that offer great resistance are called *insulators.* Electrical resistance, measured in ohms (R), is equal to the electromotive force producing a current, measured in *volts* (E), divided by the current, measured in *amperes* (I):

$$\text{ohms} = \frac{\text{volts}}{\text{amperes}} \quad \text{or} \quad R = \frac{E}{I}$$

The resistance of a conductor depends on its dimensions and its temperature as well as on the material from which the conductor is made. For example, the resistance of a wire increases as its length increases or as its diameter decreases. Generally, the resistance of a metal increases as its temperature rises.

The international standard for the ohm was adopted in 1893. It was defined as the amount of resistance to a uniform electric current offered by a thread of mercury with a cross-sectional area of one square millimeter and a length of 106.3 centimeters, at a temperature of 0° C. Engineers have worked out the resistance of standard-sized wires for people who work with electric circuits. Resistance in an electric circuit can be measured with an *ohmmeter.* More accurate measurements can be obtained by using a device called a *Wheatstone bridge* (see **Wheatstone bridge**). Gregory Benford

Ohm, Georg Simon (1787-1854), a German physicist, in 1827 described the mathematical law of electric currents called Ohm's law (see **Ohm's law**). The *ohm,* a unit of electrical resistance, was named for him. His discovery was neglected until 1833, when he became a professor of physics at Nuremberg. He was appointed a physics professor at the University of Munich in 1849.

Ohm was born in Erlangen, Germany. He graduated from the University of Erlangen. Richard G. Olson

Ohm's law is a mathematical formula that expresses the relationship between the electromotive force, electric current, and resistance in a circuit. This relationship was discovered by the German physicist Georg Ohm, and was published in 1827. When applied to a direct-current circuit, Ohm's law states that the electromotive force (E), measured in volts, equals the current (I) in amperes multiplied by the resistance (R) in ohms:

$$E = IR$$

When the law is used for an alternating-current circuit, resistance is replaced by *impedance* (Z), also in ohms. The flow of alternating current produces a *counter-electromotive force,* which resists the current. The strength of such resistance depends on how rapidly the current alternates. Impedance consists of this resistance, called *reactance,* combined with the circuit's regular resistance.

Electricians use Ohm's law to determine the efficiency of circuits. For example, they can calculate how the flow of current will be affected by various arrangements of such circuit components as connecting wires, capacitors, and resistors. Gregory Benford

Oil. Any greasy substance that does not dissolve in water, but can be dissolved in ether, is classified as an oil. There are many different kinds of oil. Most are lighter than water and are liquid at room temperature. A few, such as lard and butterfat, are solid at room temperature.

Oils may be obtained from animal, mineral, or vegetable sources. This article chiefly discusses animal and vegetable oils. For more information on mineral oils, which include fuel oils, gasoline, and other petroleum products, see **Petroleum**.

Animal and vegetable oils consist chiefly of carbon, hydrogen, and oxygen, and they belong to a family of materials called *lipids.* Animal and vegetable oils are classified as fixed or volatile, depending on whether they evaporate under normal conditions.

Fixed oils, which do not evaporate under ordinary conditions, are also called *fatty oils* or simply *fats.* They include all animal oils and many vegetable oils. Butterfat, lard, and tallow rank as the chief animal oils. Margarine and salad oil consist mainly of fixed vegetable oils. Other products that are made from fixed oils include candles, linoleum, lubricants, paint, and soap.

Butter makers churn cream to produce butter. People *render* (heat) fatty animal tissues to obtain other kinds of animal oil. Lard is made from fatty tissues of hogs, and tallow from cattle, goats, or sheep. Oils from such sea animals as fish and whales are called *marine oils.*

Most fixed vegetable oils are extracted from such seeds as corn, cottonseed, and soybeans. Processors obtain olive and palm oils from the fruit pulp surrounding the seed. For information on the processing of fixed vegetable oils, see **Vegetable oil**.

Exposure to air causes fixed oils to thicken. The degree of thickening determines whether the oil is classified as (1) drying, (2) semidrying, or (3) nondrying.

Drying oils absorb oxygen from the air to form a tough film. They are widely used to make paints and varnishes. Important drying oils include linseed, perilla, tung or chinawood, soybean, oiticica, hemp, walnut, poppy seed, and sunflower. Linseed oil comes from flax seeds. It is one of the most important drying oils. It is used in making paints and varnishes. Tung oil is a valuable oil used in waterproof varnishes and quick-drying enamels.

Semidrying oils absorb oxygen from the air to become very thick, but not hard. Cottonseed, corn, and sesame oils are of the semidrying type.

Nondrying oils absorb oxygen from the air with little increase in thickness, but they often become *rancid*—that is, they develop unpleasant odors and flavors. Olive, peanut, and grape-seed oils, butterfat, and lard are examples of nondrying types.

Volatile oils, also called *essential oils,* evaporate quickly, especially when heated. Some of these oils come from plants, and others are artificially created. People use volatile oils chiefly for their flavor or odor. The taste of such food flavorings as lemon, mint, and vanilla extracts results from the volatile oils they include. Volatile oils also flavor chewing gum, tobacco, and toothpaste. Most fine perfumes include fragrant oils obtained from roses and other flowers. Manufacturers use such volatile oils as lemon oil to give a scent to soaps and other cleaning products.

Natural volatile oils are extracted from various parts of plants, including bark, flowers, leaves, roots, seeds, and twigs. Methods of obtaining plant oils used for their scent are described in the **Perfume** article. Food processors follow similar procedures in extracting natural volatile oils for flavoring.

Manufacturers use chemical processes to make artificial volatile oils from coal, petroleum, wood, and other substances. Some artificial oils duplicate natural oils. Others differ from any substance found in nature. Such products as artificial oil of rose and artificial vanilla extract cost much less than similar natural substances.

Oil shale is a soft, fine-grained sedimentary rock from which oil and natural gas are obtained. Oil shale consists of light brown layers of silt and darker layers of *kerogen,* a waxy organic substance that originated from the remains of blue-green algae and other living matter. Vast deposits of oil shale occur in southern Brazil, northeastern China, Estonia, Sweden, and the United States.

Heating oil shale releases crude oil and natural gas from the kerogen. However, it takes huge quantities of rock to obtain a useful amount of oil. As a result, the oil is expensive to produce. The high cost of production has limited the commercial use of the oil. Only Estonia and China now use oil shale. The only commercial-scale oil shale plant in the United States closed in 1991.

Two methods are used to obtain oil from oil shale. In the first process, the mined rock is crushed, transported to a processing plant, and heated to temperatures higher than 900 °F (480 °C). The heat drives oil vapors from the rock, and they condense into liquid oil. The second process is called the *in situ* (in place) method. In this method, miners dig a hole into the bottom of a shale deposit. They then dynamite the deposit, which collapses and shatters. A mixture of air and gas is pumped into the deposit and ignited, heating the rock. Oil vapors then separate from the rock and condense, and oil is pumped out. Bob Williams

WORLD BOOK diagram

Crude oil is obtained from oil shale by a process called *retorting,* shown above. Crushed shale rock is heated to more than 900 °F (480 °C) by gas burners. The heat releases oil vapors from the rock, and the vapors liquefy in a condenser.

Oil well. See **Petroleum**.

Oilbird is a cave-dwelling bird found in the tropics of northern South America. It is related to whippoorwills, goatsuckers, and nightjars but looks more like an owl. Oilbirds have cinnamon-brown feathers with white dots. Adults measure from 12 to 18 inches (30 to 46 centimeters) long. Young oilbirds are unusually plump and contain so much oily fat that they were once slaughtered by people, who used the fat as lamp oil and cooking oil. Oilbirds are also called *guacharos.*

Bertram G. Murray, Jr., Animals Animals

Oilbirds dwell in caves in tropical regions of northern South America. They have rich brown feathers and large eyes that reflect red in the dark. Oilbirds feed on palm and laurel fruits.

Oilbirds spend most of their time roosting or flying because their feet are poorly developed for walking. They are active at night and feed largely on the fruits of palm and laurel trees.

Oilbirds build nests of seeds and bird droppings on top of rocks or ledges deep in caves. An oilbird finds its way about caves and at night by means of *echolocation.* The bird makes sharp clicking sounds that echo off objects to tell the bird where to fly. Oilbirds also make loud, shrill calls at night.

Scientific classification. The oilbird makes up the oilbird family, Steatornithidae. It is *Steatornis caripensis.*

Donald F. Bruning

Oilcloth is a heavy, waterproof cloth used to cover tables and walls that must often be washed. It is made of coarse cloth coated with heavy paint. The cloth is stretched on a frame and stiffened with glue. The paint is put on in several coats. Each coat is smoothed with pumice stone after it has dried. Patterns are then printed on, from blocks coated with paint. Oilcloth was first used in China between the 600's and 900's, and in England in the 1500's. The first American oilcloth was made in Philadelphia in 1809. Any smooth vinyl-coated fabric is sometimes called an oilcloth. Christine W. Jarvis

Oistrakh, *OY strahk,* **David** (1908-1974), was a leading Soviet violinist. He achieved fame for his brilliant technique and rich tone. Such major Soviet composers as Sergei Prokofiev and Dimitri Shostakovich wrote chamber music and violin concertos for him. Oistrakh was also a noted conductor and an outstanding teacher of the violin. One of his students was his son, Igor, who became an internationally acclaimed violinist.

Oistrakh was born in Odessa and began studying the violin when he was 5 years old. After graduating from the Odessa Conservatory in 1926, Oistrakh began performing throughout the Soviet Union. In 1934, he was appointed to the faculty of the Moscow Conservatory. Oistrakh attracted international attention in 1937, when

he won first prize in a violin competition in Brussels, Belgium. Abram Loft

Ojibwa Indians. See Chippewa Indians.

Ojos del Salado, *oh hohz dehl suh LAHD oh,* is the second highest mountain in the Western Hemisphere. Only Aconcagua is higher. Both mountains are part of the Andes range in South America. Ojos del Salado rises 22,572 feet (6,880 meters). It has four distinct peaks on the border between Argentina and Chile. Snow covers Ojos del Salado all year. For location, see **Argentina** (terrain map). Gregory Knapp

Okapi, *oh KAH pee,* is a rare animal that lives in dense forests around the Congo River basin in Africa. It was discovered there by European explorers in 1900. The

Kenneth W. Fink, Ardea

The okapi is a relative of the giraffe. It has a reddish-brown body, a white face, and white stripes on its legs. Okapis live in rain forests of the Congo River basin in Africa.

okapi stands about 5 feet (1.5 meters) high at the shoulder. It is related to the giraffe, but its neck is much shorter. The okapi has a dark chestnut body, a white face, and white stripes on its rump and upper legs. The male has a pair of short, hairy horns.

The okapi eats leaves, fruit, and seeds. It travels alone or in pairs. Its chief enemies are leopards and human beings. The okapi has keen hearing and flees when disturbed.

Scientific classification. The okapi belongs to the giraffe family, Giraffidae. It is *Okapia johnstoni.* Anne Innis Dagg

Okeechobee, Lake. See Lake Okeechobee.

O'Keeffe, Georgia (1887-1986), was an American painter who found most of her inspiration in nature. Her flower paintings, which she created throughout her career, are her best-known works. She is also famous for her paintings of animal skulls and desert landscapes. She painted in a highly personalized style, using strong, vibrant colors. Her forms are sensually smoothed and simplified, often into highly abstract designs.

O'Keeffe was born in Sun Prairie, Wis. She studied at several schools, including the Art Institute of Chicago, the Art Students League, and Columbia University. From 1912 to 1918, O'Keeffe taught in Texas, Virginia, and

Oil painting on canvas (1936); © Georgia O'Keeffe, photo by Malcolm Varon

Georgia O'Keeffe gained fame for her paintings of the desert region of the American Southwest. *Summer Days, above,* is typical of O'Keeffe's works. Animal bones, flowers, and the desert landscape appear in many of her paintings.

South Carolina. In Texas, she first became interested in the American Southwest. The region's desert landscape greatly influenced her work.

The American photographer Alfred Stieglitz first showed O'Keeffe's paintings in 1916 at "291," his experimental gallery in New York City. For years, he displayed O'Keeffe's work at two other galleries he operated in New York City. Stieglitz and O'Keeffe were married in 1924. In 1929, O'Keeffe began spending much time in New Mexico. Her husband died in 1946 and she settled near Abiquiu in 1949.

Toward the end of her life, O'Keeffe's eyesight began to fail. She then began to work with ceramics, shaping beautifully rounded, sensuous forms and pottery.

Deborah Leveton

Okefenokee Swamp, *OH kuh fuh NOH kee,* lies mostly in southeastern Georgia. A small part of it extends into northeastern Florida. Okefenokee Swamp is a marshy, subtropical wilderness. Most of it was bought by the United States government in 1937. The government has set aside about 460 square miles (1,200 square kilometers) of the region as the Okefenokee National Wildlife Refuge.

The name *Okefenokee* comes from the Indian word *Owaquaphenoga,* which means *trembling earth.* It refers to the trembling of the small bushes and water weeds that float on the lakes of Okefenokee.

The swamp covers 700 square miles (1,800 square kilometers). Fine timberlands and freshwater lakes lie next to the marshy stretches. The region is drained by the St. Marys and the Suwannee rivers. Other bodies of water wind through the swamp. There are about 25 islands.

Artstreet

Okefenokee Swamp covers about 700 square miles (1,800 square kilometers) of marshy wilderness, chiefly in southeastern Georgia. The United States government has set aside about two-thirds of the region as the Okefenokee National Wildlife Refuge. The preserve provides a recreation area for people, as well as a safe home for many unique varieties of mammals, birds, fish, and plants.

Okefenokee Swamp was once a favorite hunting ground of the Creek and Seminole Indians. Today, as a government preserve, the swamp is the home of many animals, including deer, bears, bobcats, otters, raccoons, opossums, and alligators. The swamp is also the winter refuge of many birds. There are about 50 kinds of fish in its waters. Plants that grow there include white and golden lilies, Spanish moss, and baldcypress trees.

James O. Wheeler

See also **Georgia** (map; picture).

Okhotsk, *oh KAHTSK,* **Sea of,** is a large arm of the North Pacific Ocean on the eastern boundary of Russia. It is separated from the Bering Sea on the east by Russia's Kamchatka Peninsula. The Kuril Islands on the south separate the Sea of Okhotsk from the Pacific Ocean. For the sea's location, see **Russia** (terrain map).

The Sea of Okhotsk is about 1,000 miles (1,600 kilometers) long and about 600 miles (970 kilometers) wide. It covers an area of about 615,000 square miles (1,590,000 square kilometers).

Ice covers the Sea of Okhotsk from November to April, and heavy fogs and storms occur often. But the sea is used as a trade waterway for the Russian ports of Magadan and Okhotsk. The Amur River and smaller streams empty into the Sea of Okhotsk.

Craig ZumBrunnen

Okinawa, *OH kuh NOW wuh,* or in Japanese, *AW kee NAH wah,* is the largest and most important island of the Ryukyu Islands. The Ryukyus are a chain of islands in the North Pacific Ocean that are part of Japan.

Okinawa covers 465 square miles (1,204 square kilometers). It is the largest island in Japan's Okinawa *prefecture* (district), which has a population of 1,318,220. The Okinawa prefecture also includes the southern Ryukyu Islands. Almost all of the prefecture's population lives on the island of Okinawa. Naha, the capital of Okinawa prefecture and largest city of the Ryukyus, is on Okinawa.

Okinawa was under Japanese control before World War II (1939-1945). The United States occupied Okinawa after the war and administered it and the other Ryukyu islands until 1972. In that year, the United States returned the islands to Japanese control.

Okinawa has had great military importance for the United States because it lies within easy flying distance of China, mainland Japan, the Philippines, Taiwan, and Vietnam. The United States built air bases and other installations on the island and continued to maintain them after returning control of the island to Japan. But in the mid-1990's, growing dissatisfaction among Okinawans with the U.S. military presence prompted the United States to agree to give up part of the land it administers.

Okinawa

WORLD BOOK maps

Government. Voters elect a governor to head the prefecture of Okinawa. The prefecture's legislature, the *Prefectural Assembly,* consists of 48 members. The prefecture's voters also elect five representatives to the *Diet* (national parliament) in Tokyo.

People. Okinawans look like the Japanese, but Okinawans are shorter and have darker skin. The Okinawan language belongs to the Japanese language family. However, most Okinawans only speak Japanese.

Most Okinawans live in urban areas. Naha and other cities in Okinawa have modern buildings and traffic-choked streets. A few Okinawans still live in small villages of red tile-roofed houses. Their main food is rice, but they also eat much pork. Most village people farm or fish for a living.

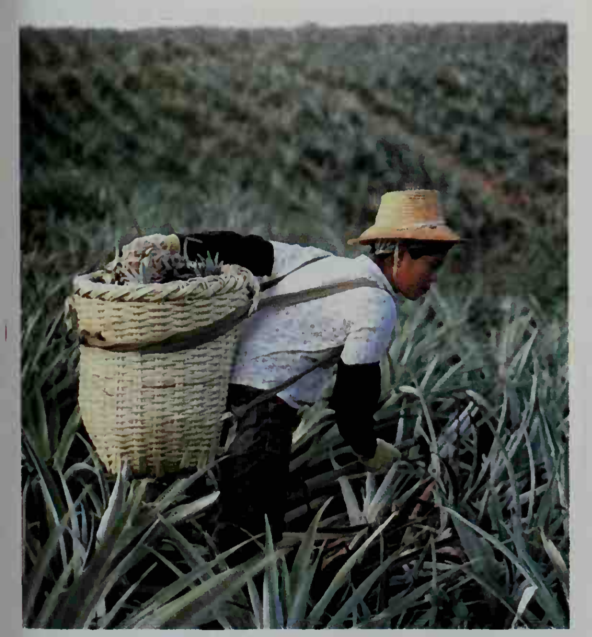
The University of the Ryukyus, in Naha, is Okinawa's major institution of higher education. About 225,000 students attend the prefecture's elementary, junior high, and high schools.

Land and climate. Okinawa is 67 miles (108 kilometers) long and from 2 to 16 miles (3 to 26 kilometers) wide. Mountains and jungle cover the northern part of the island. The southern part has low, rocky hills. Most of the people live in the south.

Okinawa has a subtropical climate. The average daily temperature in Naha is 72 °F (22 °C) the year around. Rainfall averages about 83 inches (211 centimeters) yearly, most of it falling in the typhoon season, from April to October.

Economy. Before World War II, Okinawa was a poor agricultural island. Today, it has one of the highest *per capita* (per person) incomes in East Asia. Its chief crops include pineapples, rice, sugar cane, and sweet potatoes.

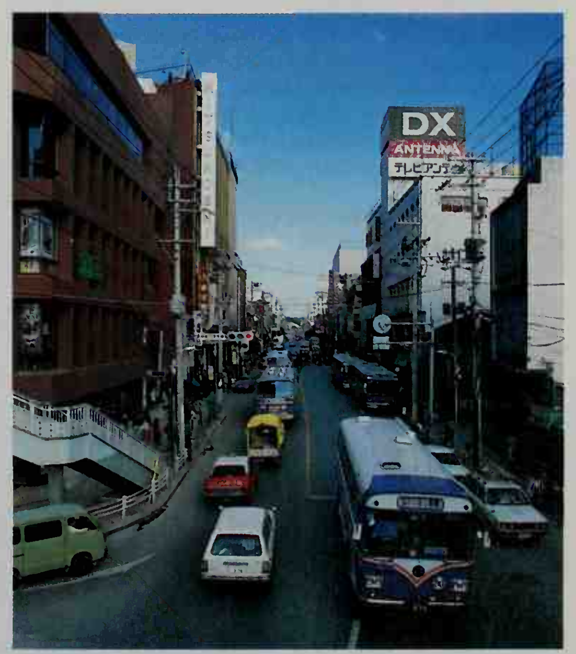
Tourism has become the island's main industry. Most of the tourists come from other parts of Japan to enjoy Okinawa's warm climate and natural beauty.



Okinawan craftworkers make ceramics, lacquerware, and woven and dyed cloth. A pottery kiln in Naha has been operating since the 1600's. Okinawan arts and crafts are prized by art collectors, especially in Japan.

History. Japan and China both claimed Okinawa and the rest of the Ryukyus until 1874, when China recognized Japan's rule. For the history of the island before that time, see the article on **Ryukyu Islands**.

One of the bloodiest campaigns of World War II was fought on Okinawa between U.S. and Japanese troops. The Americans landed on the island on April 1, 1945, and conquered it in late June. During the fighting, more than 90 percent of the island's buildings were destroyed. See **World War II** (Closing in on Japan).



The peace treaty that ended the war gave the United States control of the Ryukyu Islands. In 1950, the United States began to grant some self-rule to the Ryukyuans. It returned the northern Ryukyus to Japan in 1953 but kept Okinawa and the southern islands. The United States built military bases on Okinawa after the Chinese Communists gained control of China in 1949 and the Korean War broke out in 1950.

During the 1950's and 1960's, many Okinawans demanded that the island be returned to Japanese rule. The United States returned the island to Japan in 1972. Under an agreement between the two nations, U.S. military bases remain on Okinawa, but nuclear weapons may not be kept on the island without Japan's consent. In 1996, the United States announced that within the coming years it would return to Okinawa 20 percent of the land held by the U.S. military. David L. Howell

David Moore, Black Star

An Okinawan farmworker cuts pineapples from their plants and drops them into a basket strapped to her back. Pineapples rank among the leading exports of Okinawa.

Pan-Asia Newspaper Alliance

Naha, Okinawa's largest city, is a major commercial center on the island. The busy International Avenue, *shown here,* is the main street of the city.

© David G. Fitzgerald

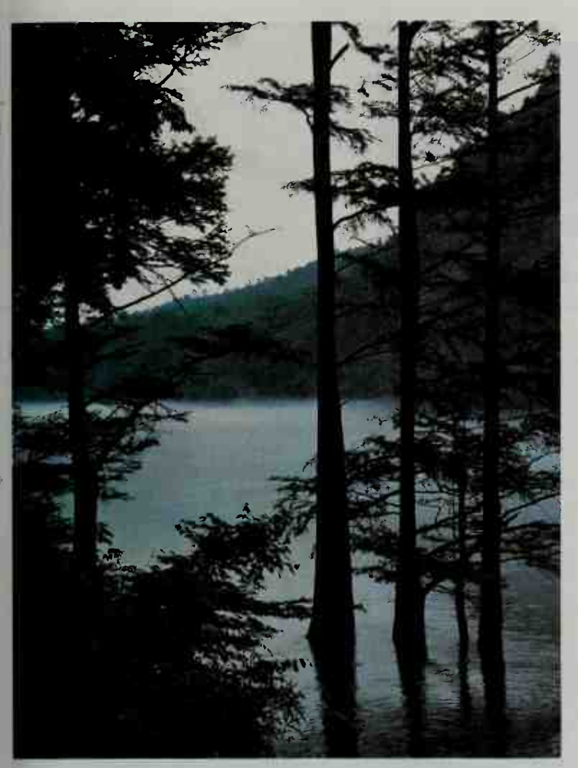
Granite mounds rise in Quartz Mountain State Park near Lugert. The state's varied landscape includes rugged hills and mountains, vast plains, green forests, and fertile farmlands.

Oklahoma *The Sooner State*

Oklahoma is a major fuel and food producing state in the southwestern part of the United States. Thousands of oil and natural gas wells dot the Oklahoma landscape. Oil pumps operate even on the front lawn of the State Capitol. Millions of white-faced beef cattle graze on Oklahoma's flat plains and low hills. Fertile fields produce vast crops of wheat.

Service industries and manufacturing are also important in Oklahoma. The state's location midway between the east and west coasts makes it an important transportation, communication, and distribution center. Oklahoma's manufacturing plants turn out large amounts of aerospace equipment, automobiles, electronic products, machinery, and tires.

The development of Oklahoma's vast natural resources began with the Indians. In the 1800's, the United States government made most of the region a huge Indian reservation. The Indians established separate nations, with their own governments and their own schools. The name *Oklahoma* is a combination of two Choctaw Indian words—*okla,* meaning *people,* and *homma,* meaning *red.*



The contributors of this article are Keith D. Harries, contributing author to The Geography of Oklahoma; *and H. Wayne Morgan, George Lynn Cross Research Professor of History at the University of Oklahoma.*

The government first opened Oklahoma to white settlement during the late 1880's. Oklahoma became known as the *Sooner State* because some settlers were there "sooner" than the land was opened. It is also called the *Boomer State,* after the promoters who "boomed" white settlement. The land was settled rapidly, and whites soon far outnumbered the Indians.

During the early 1900's, the farms and ranches of Oklahoma were fertile and productive. In the 1930's, however, a long dry period and low farm prices brought disaster to the farmers. Large numbers of farmers and other workers left the state, and the population of Oklahoma dropped.

Both these periods of Oklahoma history have become famous. The story of the state's farmers and cattlemen in territorial days is told in the musical play *Oklahoma!* The title song from the play became Oklahoma's state song. John Steinbeck's famous novel *The Grapes of Wrath* included a fictional, but widely accepted, description of the drought of the 1930's.

Today, farmers protect their land from drought with modern soil and water conservation methods. The state's oil and gas wells continue to yield their valuable products, and the state is working to attract new industries. Oklahoma City, the state capital and largest city in population, is one of the largest cities in area in the United States. It covers about 647 square miles (1,676 square kilometers).

Beavers Bend State Park has scenic woodlands covering over 3,500 acres (1,400 hectares) in the Ouachita Mountains.

Interesting facts about Oklahoma

WORLD BOOK illustrations by Kevin Chadwick

Downtown Guthrie has 100 buildings—about 90 per cent of the downtown area—on the National Register of Historic Places. Guthrie was the first capital of Oklahoma. But in 1910, the capital was moved to Oklahoma City. The booming town suddenly became quiet. Buildings erected during the days of early statehood were preserved and older buildings were not torn down to make room for newer ones. Thus, the town became a treasure of historical architecture. A restoration project in the 1980's brought the town back to life as an example of turn-of-the-century architecture.

Guthrie

The first automatic parking meter was installed in Oklahoma City on July 16, 1935.

Oklahoma City was barren prairie on the morning of April 22, 1889, but its population numbered more than 10,000 by nightfall. That day unassigned land was opened to settlement.

Oklahoma is a major United States center of Indian culture. The state has a large and varied Indian population. More than 60 different Indian tribes live in Oklahoma.

The Oklahoma State Capitol is the nation's only statehouse with working oil wells on its grounds. The wells were drilled after the capitol was built, and the state owns the mineral rights to its grounds.

Indian culture

Randy Bennett, Oklahoma City Public Information Office

Oklahoma City is the capital and largest city of Oklahoma. Modern buildings stand close together in the downtown section of the city, *left.* Myriad Gardens, in the foreground, provides open space in the crowded downtown area.

Oklahoma in brief

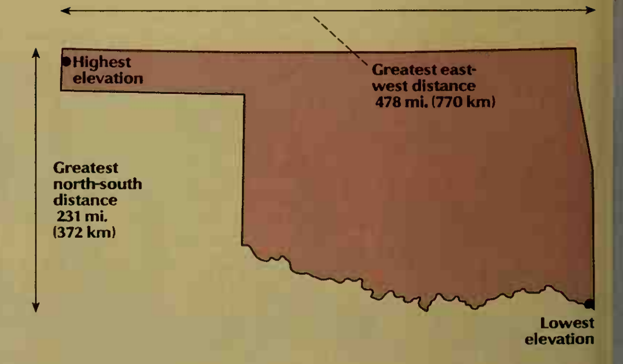
Symbols of Oklahoma

The state flag, adopted in 1925, displays an Osage warrior's shield decorated with eagle feathers. Crossing the shield are two symbols of peace—an olive branch and a peace pipe. On the state seal, adopted in 1907, an Indian and a white frontiersman shake hands before the figure of Justice to show the cooperation of the people of Oklahoma. The large star displays symbols of the Five Civilized Tribes, which moved to the region in the 1800's.

State flag

State seal

Oklahoma (brown) ranks 18th in size among all the states and is the smallest of the Southwestern States (yellow).



The State Capitol is in Oklahoma City, the capital of Oklahoma since 1910. Guthrie served as capital from 1890 to 1910.

General information

Statehood: Nov. 16, 1907, the 46th state.
State abbreviations: Okla. (traditional); OK (postal).
State motto: *Labor Omnia Vincit* (Labor Conquers All Things).
State song: "Oklahoma!" Words by Oscar Hammerstein II; music by Richard Rodgers.

Land and climate

Area: 69,903 sq. mi. (181,048 km²), including 1,224 sq. mi. (3,171 km²) of inland water.
Elevation: *Highest*—Black Mesa, 4,973 ft. (1,516 m) above sea level. *Lowest*—287 ft. (87 m) above sea level along the Little River in McCurtain County.
Record high temperature: 120 °F (49 °C) at Alva on July 18, 1936; at Altus on July 19 and Aug. 12, 1936; at Poteau on Aug. 10, 1936; at Tishomingo on July 26, 1943; and at Tipton on June 27, 1994.
Record low temperature: −27 °F (−33 °C) at Vinita on Feb. 13, 1905, and at Watts on Jan. 18, 1930.
Average July temperature: 82 °F (28 °C).
Average January temperature: 37 °F (3 °C).
Average yearly precipitation: 33 in. (84 cm).

Important dates

- **1541** Francisco Vásquez de Coronado crossed western Oklahoma in search of gold.
- **1682** La Salle claimed Oklahoma as part of French Louisiana.
- **1803** The United States bought the Oklahoma region, except the Panhandle, as part of the Louisiana Purchase.
- **1824** The U.S. government established Fort Gibson and Fort Towson, the region's first military posts.

For information on the economy, write to: Oklahoma Department of Commerce, 900 N. Stiles, P.O. Box 26980, Oklahoma City, OK 73126-0980.

1893 The Cherokee Outlet was opened to white settlement, creating Oklahoma's greatest land rush.

1907 Oklahoma became the 46th state on November 16.

1928 The Oklahoma City oil field opened.

1990 Oklahoma became the first state to pass term limits on members of its state Legislature.

People

Population. The 2000 United States census reported that Oklahoma had 3,450,654 people. The state's population had increased about 10 percent over the 1990 census figure, 3,145,585. According to the 2000 United States census, Oklahoma ranks 27th in population among the 50 states.

Approximately three-fifths of the people live in the state's five metropolitan areas (see **Metropolitan area**). These metropolitan areas, in order of population, are Oklahoma City; Tulsa; Lawton; Enid; and Fort Smith, Arkansas, which extends into Sequoyah County in Oklahoma. For the populations of the five metropolitan areas, see the *Index* to the political map of Oklahoma in this article.

Oklahoma has about 20 cities with populations of over 20,000 people. The majority of these cities are located near Oklahoma City or Tulsa. Oklahoma City is a rapidly expanding center of industry and trade. Tulsa started as a Creek Indian village in the early 1800's. The city boomed after oil was discovered in nearby Red Fork in the early 1900's. Norman, the state's third-largest city, is the home of the University of Oklahoma. Lawton serves Fort Sill, a neighboring military center.

Oklahoma's largest population groups include people of German, Irish, American Indian, and English descent. American Indians make up about 8 percent of the population.

Schools. The first schools in Oklahoma were established for the Indians in the 1820's by missionaries. By the late 1840's, several tribes, including the Cherokee and the Choctaw, had established their own advanced educational systems. Schools for white children were first established in Oklahoma in 1890.

Oklahoma's present school system is headed by an elected superintendent of public instruction. The superintendent works with a board of education whose members are appointed by the governor. The U.S. government maintains two boarding schools to assist in the education of Indian children. By law, children from age 5 through age 17 must attend school. For the number of

Population density

About half the people of Oklahoma live in the metropolitan areas of Oklahoma City and Tulsa. Western Oklahoma, including a narrow strip called the Panhandle, is more thinly populated.

Persons per sq. mi.	Persons per km²
More than 50	More than 20
25 to 50	10 to 20
10 to 25	4 to 10
Less than 10	Less than 4

Downtown Tulsa includes Bartlett Square, a popular outdoor gathering place. Tulsa, Oklahoma's second largest city, lies along the Arkansas River in the northeastern part of the state.

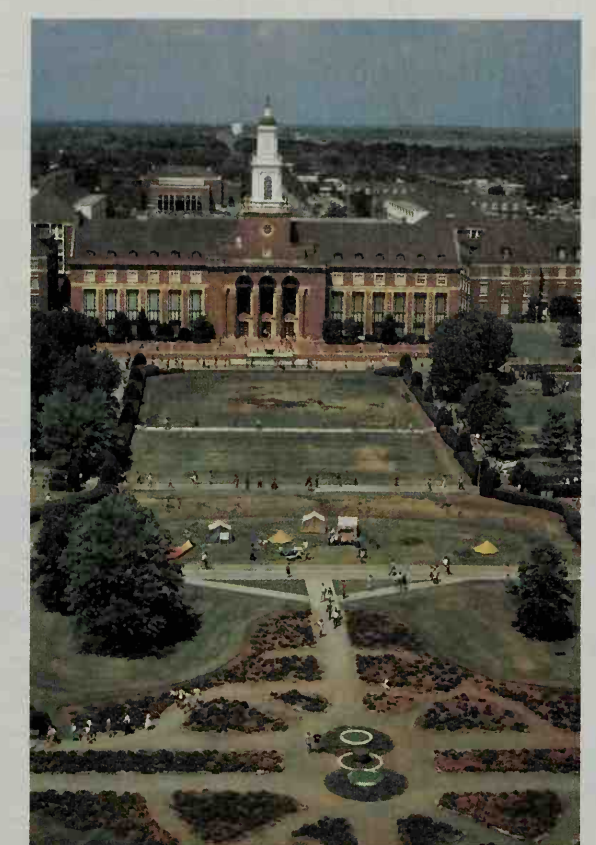
students and teachers in Oklahoma, see **Education** (table).

Libraries. Oklahoma has about 200 public libraries and about 45 college and university libraries. The first public library in Oklahoma was founded in Guthrie in 1901.

The Oklahoma Department of Libraries and the library division of the Oklahoma Historical Society are both located in Oklahoma City. The University of Oklahoma Library in Norman has the DeGolyer collection on the history of science and technology, the Bass Business History collection, and a collection of materials on Western history.

Museums. Oklahoma's museums own many fine collections on Indian history and art. The Thomas Gilcrease Institute of American History and Art, which is located in Tulsa, is devoted largely to Indian history and art. The Woolaroc Museum near Bartlesville owns one of the world's finest collections of Indian blankets. Lawton is the home of the Museum of the Great Plains. The Southern Plains Indian Museum and Crafts Center is located in Anadarko.

The Oklahoma State Museum of History is in Oklahoma City. The National Cowboy and Western Heritage Museum, also in Oklahoma City, features art of the American West. In addition, it houses the Rodeo Hall of Fame, the Hall of Great Westerners, and the Hall of Great Western Performers.



The Kirkpatrick Science and Air Space Museum at Omniplex in Oklahoma City includes exhibits that visitors are encouraged to touch and explore. The Philbrook Museum of Art in Tulsa displays paintings from the Italian Renaissance and collections of Asian art. Fort Sill, a military center near Lawton, has an artillery museum that displays unusual weapons.

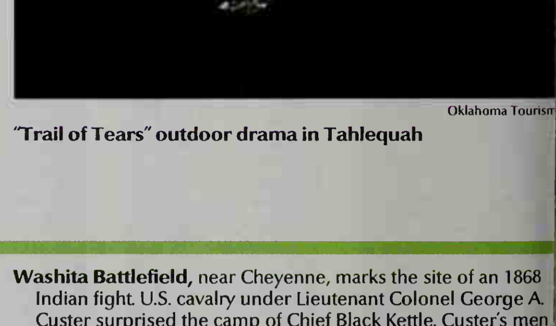
Visitor's guide



Will Rogers, the famous Oklahoma cowboy humorist, once said: "There ought to be a law against anybody going to Europe until they have seen the things we have in this country." Rogers may have been thinking of some of the scenic spots in his home state. Oklahoma's attractions include beautiful natural settings, Indian villages, and striking modern buildings.

Many Oklahoma towns and cities hold annual celebrations to honor Indian and pioneer days. One of the most popular annual events in Oklahoma is the "Trail of Tears" outdoor drama. This play takes place in an 1,800-seat amphitheater in Tahlequah. "Trail of Tears" is performed every night, except Sunday, from early June through Labor Day.

Places to visit

Following are brief descriptions of some of Oklahoma's many interesting places to visit:

Cherokee Heritage Center, southeast of Tahlequah, includes the Tsa-La-Gi Ancient Village, a re-creation of an Indian village. Cherokee Indians give tours during the summer months.

Creek Capitol, in Okmulgee, is the building from which Creek Indians ruled their republic.

Fort Sill, a military center near Lawton, includes three historical sites—Stone Corral, Old Guardhouse, and an artillery museum. The fort was established in 1869.

National Cowboy & Western Heritage Museum, in Oklahoma City, displays famous paintings and sculptures of the American West. The center includes the Rodeo Hall of Fame and a re-creation of an old pioneer town.

National Softball Hall of Fame, in Oklahoma City, has a hall of fame, paintings, and historical displays.

Oklahoma City National Memorial, in Oklahoma City, honors the victims, survivors, and rescuers of the bombing of the Murrah Federal Building in 1995.

Thomas Gilcrease Institute of American History and Art, in Tulsa, is an art gallery and library. Exhibits include many paintings on the history of the American West.

Washita Battlefield, near Cheyenne, marks the site of an 1868 Indian fight. U.S. cavalry under Lieutenant Colonel George A. Custer surprised the camp of Chief Black Kettle. Custer's men killed or wounded more than 100 Cheyenne Indians, including women and children.

Will Rogers Memorial, in Claremore, contains paintings, manuscripts, and other personal belongings of the Oklahoma-born humorist Will Rogers. Rogers is buried at the site.

Woolaroc Museum, southwest of Bartlesville, displays over 55,000 historical exhibits. Much of its collection deals with the history of the Southwest, including paintings by artists Frederic Remington and Charles Russell.

National Recreation Area and Forest. The Chickasaw National Recreation Area lies in south-central Oklahoma. The area has six developed campgrounds for public use. It also has facilities for swimming and boating at the Lake of the Arbuckles. Two sections of the Ouachita National Forest are located in southeastern Oklahoma.

State parks. Oklahoma has 58 state parks and 5 state resorts that offer a wealth of water sports, hiking, camping, and other recreational activities. For information about Oklahoma's state parks and resorts, write: Oklahoma Tourism, P.O. Box 60789, Oklahoma City, OK 73146.

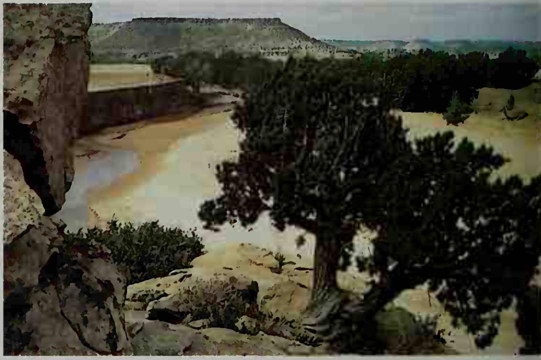
Land and climate

Land regions. Oklahoma has 10 main land regions. These regions are (1) the Ozark Plateau, (2) the Prairie Plains, (3) the Ouachita Mountains, (4) the Sandstone Hills, (5) the Arbuckle Mountains, (6) the Wichita Mountains, (7) the Red River Region, (8) the Red Beds Plains, (9) the Gypsum Hills, and (10) the High Plains.

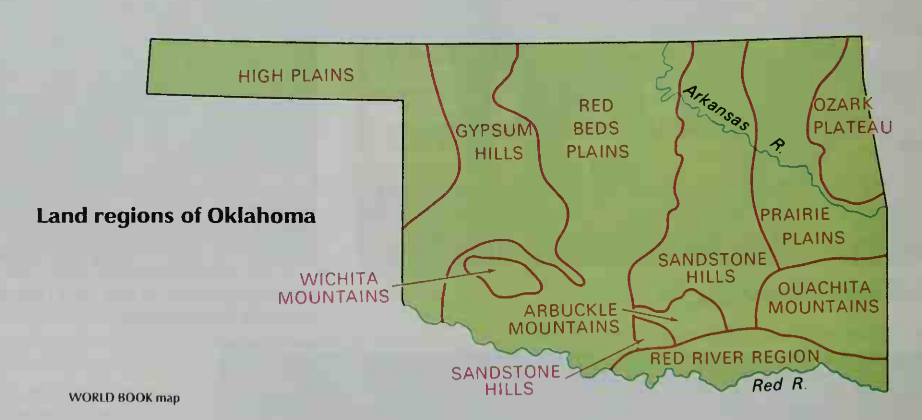
The Ozark Plateau extends into the northeastern part of Oklahoma from Missouri and Arkansas. This hilly region has swift streams and steep-sided river valleys. The areas between the river valleys are broad and flat. Steep bluffs have been formed where streams cut into the plateau.



The Prairie Plains include the land west and south of the Ozark Plateau. Farming and cattle ranching are the most important activities in this region. The Arkansas River Valley, east of Muskogee, produces such vegetable crops as spinach, snap beans, and carrots. Most of the state's coal and large amounts of petroleum come from this region.

The Ouachita Mountains rise in the southeastern part of the state on the border between Oklahoma and Arkansas. These mountains are a series of high sandstone ridges that form the roughest land surface in Oklahoma. The ridges run in a general east-west direction. They include Blue Bouncer, Buffalo, Jackfork, Kiamichi, Rich, and Winding Stair. The narrow valleys between the ridges have spring-fed streams. Lumbering is the region's most important industry.

The Sandstone Hills region extends south from the border with Kansas to near the Red River in southern Oklahoma. It is a region of hills 250 to 400 feet (76 to 120 meters) high. Many areas are covered with blackjack and post oak forests. Much of the early Oklahoma oil development took place in these hills. The Sandstone Hills region still has important oil fields. Farming is also important there.



The Arbuckle Mountains are wedged into an area of 1,000 square miles (2,600 square kilometers) in south-central Oklahoma. Millions of years ago these were tall mountains. Erosion has worn them down until they now rise only 600 to 700 feet (180 to 210 meters) above the surrounding plains. The erosion uncovered unusual rock formations that are often studied by geology students. The principal formations of this region include conglomerates, granite, limestone, sandstone, and shale. Ranchers use the land to raise cattle.

The Wichita Mountains are rough granite peaks in southwestern Oklahoma. The region has many small artificial lakes. These lakes were created by damming the mountain streams to provide water for animals, and to control soil erosion. Most of this region lies within the Fort Sill Military Reservation and a federal wildlife refuge.

© David G. Fitzgerald

Rugged mesas rise in the Oklahoma Panhandle, which forms part of the High Plains region of northwestern Oklahoma. The rest of this region consists mainly of level grassland.

The Red River Region is a rolling prairie and forest area. Much of the soil is sandy and very fertile. Farmers in the region grow cotton, peanuts, and vegetables.

The Red Beds Plains extend from Kansas to Texas in a wide sweep through the middle of Oklahoma. Soft red sandstone and shale lie under the soil. This gently rolling plain, Oklahoma's largest land region, slopes downward from west to east. The eastern part has forested areas and the western part is mostly grassy. The region has fairly fertile soil. Farmers grow cotton and wheat in the southwestern part. Oil fields have been developed in some parts of the Red Beds Plains.

The Gypsum Hills, west of the Red Beds Plains, extend northward to the High Plains. These hills rise from 150 to 200 feet (46 to 61 meters), and are capped by layers of gypsum 15 to 20 feet (4.6 to 6.1 meters) thick. They are sometimes called the Glass, or Gloss, Mountains, because the gypsum sparkles like glass in the sun.

The High Plains, an area of level grassland, occupy the northwestern section. This region, which is part of the vast Interior Plain of North America, includes Oklahoma's Panhandle. The Panhandle is the western portion of Oklahoma, a strip of land 166 miles (267 kilometers) long and 34 miles (55 kilometers) wide. The land of the High Plains rises from about 2,000 feet (610 meters) on the eastern edge of the region to 4,973 feet (1,516

Oklahoma Tourism

Turner Falls tumbles 77 feet (23 meters) into Honey Creek in the Arbuckle Mountains region of south-central Oklahoma. Erosion has created unusual rock formations in this region.

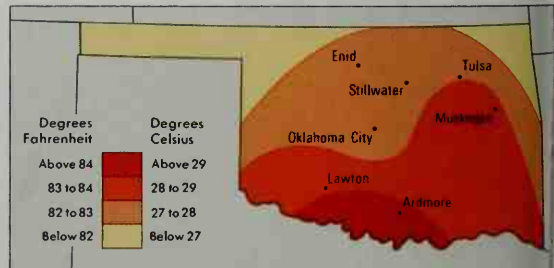
Average yearly precipitation

Oklahoma has wide differences in precipitation. The amount of precipitation decreases from the east to the west part of the state. Most of the snow falls in northwestern Oklahoma.



Average January temperatures

Oklahoma has mild winters. The temperatures are highest in the south and steadily decrease to the north. The northern border is the only part of the state that averages below freezing.

Average July temperatures

Oklahoma has hot summers with little variation in temperatures throughout the state. The northeastern corner and the Panhandle area to the west have the coolest summer temperatures.

WORLD BOOK maps

meters) at Black Mesa, the highest point in Oklahoma, in the northwestern corner of the state.

Rivers and lakes. Oklahoma is drained by two great river systems—the Red and the Arkansas. These systems carry water from the state's rivers and streams eastward to the Gulf of Mexico. The winding Red River forms Oklahoma's southern boundary with Texas. Its main tributaries drain southern Oklahoma. These streams include the Blue, Kiamichi, Little, Mountain Fork, and Washita rivers, Cache Creek, and the North Fork of the Red River.

The Arkansas River flows through northeastern Oklahoma. Its principal tributaries flow in a broad, irregular semicircle across the entire width of the state. These include the Canadian and the Cimarron rivers. The Chikaskia, Illinois, Neosho (or Grand), Poteau, Salt Fork, and Verdigris rivers, which drain northern and eastern Oklahoma, are also important branches.

Oklahoma has more than 200 artificially created lakes and about 100 small natural lakes. Lake Texoma, covering 91,200 acres (36,910 hectares), is the most popular resort center. Part of it lies in Texas. Lake O' The Cherokees is in northeastern Oklahoma. It backs up the waters of the Neosho River for 65 miles (105 kilometers). Lake Eufaula, in the east-central portion, covers over 100,000 acres (40,000 hectares). Fort Gibson Lake, Greenleaf Lake, Lower Spavinaw Lake, Upper Spavinaw Lake, Tenkiller Ferry Lake, and Lake Wister are in eastern Oklahoma. They have resorts for fishing and boating. Other large lakes and reservoirs in Oklahoma include Altus, Canton, Carl Blackwell, Ellsworth, Fort Supply, Foss, Great Salt Plains, Hefner, Heyburn, Hulah, Keystone, Lawtonka, Little River, McAlester, Murray, Oologah, Overholser, and Shawnee.

Plant and animal life. Forests cover about a fifth of Oklahoma. Important trees include ashes, elms, hickories, oaks, pines, sweet gums, and walnut trees. The main commercial forests are in the eastern and southeastern parts of the state.

Prairie grasses in Oklahoma provide grazing for millions of cattle. Among these grasses are bluestems, Indian grass, sand grass, and the shorter buffalo grass, grama, and wire grass. Other common prairie plants are mesquite and sagebrush. Dogwoods and redbuds grow in the east, central, and southern areas. Anemones, goldenrods, wild indigos, petunias, phlox, primroses, spiderworts, sunflowers, black-eyed Susans, verbena, and violets grow in all regions of Oklahoma.

Armadillos, coyotes, prairie dogs, and rabbits are common on the plains of Oklahoma. Forest animals include deer, minks, opossums, raccoons, gray and red foxes, and gray and fox squirrels. Common birds in the state include blue jays, cardinals, crows, doves, meadowlarks, mockingbirds, robins, scissor-tailed flycatchers, and house sparrows. Fishes in Oklahoma's waters include bass, buffalo fish, carp, catfish, crappie, drumfish, paddlefish, and sunfish.

Climate. Most of Oklahoma has a warm, dry climate. Northwestern Oklahoma is cooler and drier than the southeastern part. *Precipitation* (rain, melted snow, and other forms of moisture) varies greatly throughout the state. Average precipitation ranges from 50 inches (130 centimeters) a year in the southeast to 15 inches (38 centimeters) in the western Panhandle. Snowfall ranges from about 2 inches (5 centimeters) a year in the southeast to 25 inches (64 centimeters) in the northwest. The Panhandle gets the most snow.

The average July temperature in Oklahoma is 82 °F (28 °C), and the average January temperature is 37 °F (3 °C). The state's highest temperature, 120 °F (49 °C), was recorded on four occasions during the summer of 1936—at Alva on July 18, at Altus on July 19 and August 12, and at Poteau on August 10. The same figure was reached at Tishomingo on July 26, 1943, and at Tipton on June 27, 1994. The record low temperature, −27 °F (−33 °C), was registered at two locations—at Vinita on Feb. 13, 1905, and at Watts on Jan. 18, 1930.

Economy

Service industries, taken together, account for the largest part of Oklahoma's *gross state product*—the total value of goods and services produced within a state in a year. Community, business, and personal services form the leading service industry group. Manufacturing and mining also bring in much income. Oklahoma ranks among the leading producers of natural gas and petroleum. Electronic components are the leading manufactured product. Beef cattle are the leading farm product.

Natural resources. Oklahoma has vast reserves of minerals and large areas of fertile soils. Its mineral wealth includes petroleum and natural gas. Large supplies of water and a favorable climate combine with rich soils to make Oklahoma a major food producer.

Minerals. The state's oil reserves are among the largest in the nation. Natural gas is also present in most of the oil fields. Deposits of petroleum and natural gas have been found in nearly every county in Oklahoma.

Rich beds of coal lie in the east-central and northeastern parts of the state. The mountainous regions have stone and clays. Other mineral resources include limestone, gypsum, salt, and sand and gravel. Helium has

Production and workers by economic activities

Karl Kummels, Shostal

An oil derrick rises from the Oklahoma plains, symbolizing the importance of petroleum to the state's economy. Oklahoma ranks among the leading oil-producing states.

been found in the natural gas of the Panhandle.

Soil varies from the fertile deposits in the river valleys to the unproductive shale and granite of the mountains. Much of the plains and grasslands area has a rich, productive soil. Other areas have poor red clay soil.

Service industries account for the largest portion of Oklahoma's gross state product. Most service industries are concentrated in the state's metropolitan areas.

Community, business, and personal services form Oklahoma's leading industry group in terms of the gross state product. This industry group also employs more people than any other industry in Oklahoma. Community, business, and personal services consist of a variety of economic activities, including private health care, equipment rental companies, telemarketing firms, and repair shops. Companies that rent oil field equipment are important to Oklahoma. Several rental car companies have their national telephone reservation systems based in the state.

Wholesale and retail trade ranks second among Oklahoma's service industries. The wholesale trade of food products, grain, oil and gas, and transportation equipment is important in the state. A leading wholesale food distributor, Fleming Companies, is based in the state. Major types of retail businesses in Oklahoma include automobile dealerships, discount stores, food stores, and service stations.

Government services rank third. Government services include public schools and hospitals, and military bases. The University of Oklahoma Health Sciences Center in Oklahoma City is one of the nation's leading medical facilities. Tinker Air Force Base, near Oklahoma City, is a major employer in the state.

The finance, insurance, and real estate group ranks next among the service industries. Real estate is important because of the costs of buying and selling homes and other property. Increasing demand for office space in the state's large cities also benefits the industry. Tulsa and Oklahoma City are the chief financial centers.

Transportation, communication, and utilities rank fifth among service industries in Oklahoma. Pipeline companies transport the state's huge oil and gas production. American Airlines has a large facility in Tulsa. Telephone companies are the most important part of the communications sector. Utilities supply electric, gas, and water service. More information about transportation and communication appears later in this section.

Manufacturing. Goods produced in Oklahoma have a *value added by manufacture* of about $17 billion a year. Value added by manufacture represents the increase in value of raw materials after they become finished products.

Computer and electronic equipment is Oklahoma's leading manufactured product in terms of value added by manufacture. Tulsa is a production center for electronic components and military communication systems. Oklahoma City factories make telephone equipment.

Machinery ranks second among Oklahoma's manufactured products. Several cities make oil field machinery.

Economy of Oklahoma

This map shows the economic uses of land in Oklahoma and where the state's leading farm and mineral products are produced. Major manufacturing centers are shown in red.

- Mostly cropland
- Woodland mixed with cropland
- Grazing land mixed with cropland
- Grazing land mixed with shrubland
- Mostly forest land
- Manufacturing center
- Mineral deposit

WORLD BOOK map

Other types of machinery made in the state include construction machinery, machine parts, and refrigeration and heating equipment.

Other products made in Oklahoma, in order of value added by manufacture, include fabricated metal products, chemicals, transportation equipment, and rubber and plastic products. The Tulsa area produces large amounts of structural metal. Fertilizer ranks among Oklahoma's leading chemical products. Plants in Tulsa make aircraft and aerospace equipment. The Oklahoma City area has a large automobile assembly plant. Factories in Ardmore, Lawton, and Oklahoma City produce tires.

Mining. Natural gas and petroleum are Oklahoma's leading mineral products by far. Oklahoma ranks among the leading states in both natural gas and petroleum production. The heaviest natural gas production occurs in the western part of the state. Two-thirds of Oklahoma's gas is piped to other states. Central Oklahoma is the leading area for petroleum production. Phillips Petroleum, one of the world's largest oil and gas companies, is based in Bartlesville.

Other mineral products include coal, crushed stone, iodine, and sand and gravel. LeFlore County produces the most coal. Limestone quarries in northeast and south-central Oklahoma provide much of the crushed stone. Oklahoma is the only state that produces iodine. Woodward County produces most of it. Sand and gravel come mainly from pits near Oklahoma City and Tulsa.

Agriculture. Farmland covers about three-fourths of Oklahoma. The state has about 83,000 farms and ranches. The production of beef cattle is the leading source of agricultural income, and Oklahoma is one of the country's most important sources of beef. The state has more than 5 million beef cattle.

Cowhands still ride the Oklahoma range, but ranching has become a modern business. Many ranchers graze their cattle on the range for a time, and then take them to *feed lots.* A feed lot is an enclosed area where cattle are fed to fatten them for market. These animals do not need to search for feed, so they gain weight more rapidly than range cattle and bring higher prices. Other important livestock income comes from chickens, eggs, hogs, milk, turkeys, and farm-raised catfish.

Winter wheat is the state's most valuable field crop, and Oklahoma is a leading wheat-growing state. Wheat fields are harvested early each summer by lines of combines. Hay ranks second in value among Oklahoma's crops. Other important crops include corn, cotton, grain sorghum, peanuts, and soybeans. Eastern and central Oklahoma produce peaches and pecans. Greenhouse and nursery products are an important source of income.

Electric power. Coal-burning plants provide about 60 percent of Oklahoma's electric power. Plants that burn natural gas supply about 33 percent of the electric power. Hydroelectric plants provide most of the rest.

Transportation. Oklahoma has over 112,000 miles (180,000 kilometers) of roads and highways. Oklahoma has an extensive system of toll highways, including the Turner Turnpike, which links Oklahoma City and Tulsa.

Hitachi America Ltd.

Manufacturing computer components is an important economic activity in Oklahoma. The employee shown here is monitoring the production of circuit boards at a plant in Norman.

Tom McHugh, Photo Researchers

Beef cattle graze in a field of tall grass near Cleo Springs. The production of beef cattle is Oklahoma's leading source of agricultural income.

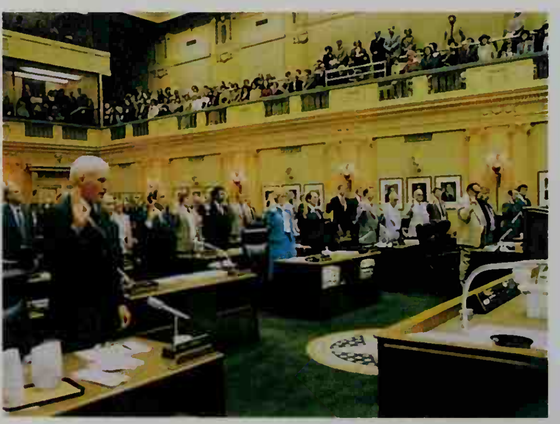
Several rail lines provide freight service in Oklahoma. The state's first railroad was the Missouri-Kansas-Texas Railroad, called the "Katy." It was built across Oklahoma to Denison, Texas, from 1870 to 1872. Passenger trains connect Oklahoma City with Fort Worth, Texas. Oklahoma City and Tulsa have the state's major commercial airports. Tulsa and Muskogee are Oklahoma's chief ports. The McClellan-Kerr Arkansas River Navigation System links these two port cities with Mississippi River ports.

About 35,000 miles (56,000 kilometers) of pipelines carry Oklahoma's oil, natural gas, and refined products to other states. Most of the pipelines run through central Oklahoma from southwest to northeast.

Communication. Oklahoma has about 200 newspapers, including about 25 dailies. The first newspaper, the *Cherokee Advocate,* was published in Tahlequah in 1844. It was printed in both English and Cherokee. Today, the largest papers are *The Daily Oklahoman* of Oklahoma City and the *Tulsa World.* About 90 periodicals are published in the state.

Station WKY in Oklahoma City was the first commercial radio station in Oklahoma. It went on the air in 1921. The state's first television stations, KTVY in Oklahoma City and KOTV in Tulsa, began regular broadcasts in 1949. Today, Oklahoma has about 20 television stations and 150 radio stations. Cable television systems and Internet providers serve many Oklahoma communities.

Government



Constitution. The Oklahoma Constitution was adopted in 1907, the year Oklahoma became a state. It may be amended by a majority vote of the people. Amendments may be proposed by the Legislature or by petitions from the voters. A constitutional convention may be called by the Legislature, subject to voter approval. The Constitution contains initiative and referendum clauses that allow the voters to propose and pass laws directly (see **Initiative and referendum**).

Executive. The governor is elected to a four-year term and may serve an unlimited number of terms, but not more than two terms in a row. The governor appoints the secretary of state and the heads of the chief revenue and budget departments. Some department heads are chosen by a board or by a commission. The lieutenant governor, attorney general, treasurer, auditor and inspector, superintendent of public instruction, insurance commissioner, labor commissioner, and corporation commissioners are all elected to serve four-year terms.

Legislature of Oklahoma consists of a Senate with 48 members and a House of Representatives with 101 members. Each senator and representative is elected from a separate district. Senators are elected to four-year terms and representatives to two-year terms. Each senator and representative is limited to no more than 12 total years of elected service as a state legislator. The Legislature meets in annual sessions that begin on the first Monday in February. In odd-numbered years, the Legislature also meets on the first Tuesday after the first Monday in January to verify election results.

Courts. The Oklahoma Supreme Court has 9 justices. They select a chief justice from their group. The governor appoints the justices with the advice of a judicial nominating commission. At the first general election following the appointment, voters decide on nonpartisan ballots whether to retain or dismiss the justice. A vote of retention means the justice may then serve a six-year term. The state also has a Court of Civil Appeals with at least 12 judges and a Court of Criminal Appeals with 5 judges. All of these judges are chosen in the same way that Supreme Court justices are selected.

Local government in Oklahoma operates in 77

Oklahoma Capitol

The Oklahoma House of Representatives meets in the House chambers in the State Capitol in Oklahoma City.

counties and about 590 cities and towns. The counties have three commissioners, each elected from a separate district. Most cities and towns use the mayor-council or council-manager form of government. Cities of over 2,000 population can adopt and amend their own charters, and thus can take some control over their affairs.

Revenue. State taxes, including money from licenses, permits, and fees, provide more than half of the state government's *general revenue* (income). Major sources of tax revenue include a sales tax, a personal income tax, and a severance tax on petroleum and natural gas production. Most of the rest of the revenue comes from bond sales and U.S. government programs.

Politics. Oklahoma was once almost solidly Democratic. The state began to develop a two-party system during the 1960's. Oklahoma voters elected the state's first Republican governor in 1962. Oklahomans have favored Republican candidates in most presidential elections held since 1948. For Oklahoma's voting record in presidential elections, see **Electoral College** (table).

History

Early days. Before white people came, bands of Indians roamed the plains of the region that now includes Oklahoma. The Indians followed the huge herds of buffalo that grazed on the grasslands. The tribes included the Arapaho, Caddo, Cheyenne, Comanche, Kiowa, Osage, Pawnee, and Wichita.

Europeans first reached the Oklahoma region in 1541. That year, the Spanish explorer Francisco Vásquez de Coronado led an expedition from Tiguex, N. Mex. He reached what is now Oklahoma. Later the same year, Hernando de Soto, another Spaniard, probably entered the area. Both Coronado and De Soto were searching for gold, but they found none.

In 1682, the French explorer Robert Cavelier, Sieur de La Salle, traveled down the Mississippi River. He did not reach the Oklahoma area. However, he claimed for France all the land drained by the Mississippi, including the Oklahoma region. Soon afterward, other French explorers and traders entered the Oklahoma area.

American ownership. France claimed the Oklahoma region as part of Louisiana until 1762, when France ceded Louisiana to Spain. Napoleon regained the province for France in 1800, but he needed money to fight wars in Europe. In 1803, he sold Louisiana to the United States (see **Louisiana Purchase**).

Congress reorganized the administration of Louisiana several times. The section that included present-day Oklahoma was first called the District of Louisiana. In 1805, it became the Louisiana Territory. Seven years later, in 1812, the Missouri Territory was organized from the Louisiana Territory. In 1819, the United States settled several boundary disputes with Spain. As a result, the present Oklahoma Panhandle, one of the disputed areas, was given to Spain. The rest of Oklahoma became part of the Arkansas Territory, which was created in 1819. Miller Court House (in present-day McCurtain County), Salina, and Three Forks were among the first white settlements established in Oklahoma.

The Indian nations. After 1819, the federal government began prodding the Indian tribes in the southeastern United States to move to the Oklahoma area. The tribes—the Cherokee, Chickasaw, Choctaw, Creek, and Seminole—had lived in close contact with white people for more than a hundred years. They adopted many of the habits and customs of the whites, and became known as the Five Civilized Tribes.

In the early 1800's, Oklahoma was largely unoccupied. In 1824, to prepare the area for the Indian migration, the U.S. Army built Fort Towson and Fort Gibson. The government soon forced the five tribes to give up most of their eastern lands and begin the move west.

Between 1830 and 1842, sad processions of Indians moved into the hills and grasslands of eastern Oklahoma. Thousands died along the way. The Indians who moved included the Cherokee, who called their own trip the *Trail of Tears.* This term is sometimes used to refer to the removal of the other tribes as well.

The immigrant Indians were given the right to all of present-day Oklahoma except the Panhandle. Each of the five tribes formed a nation. By treaties, the United States promised to protect the Indian nations. The government guaranteed that the Indians would own their lands "as long as grass shall grow and rivers run." Each Indian nation established its own legislature, courts, and written laws, and built its own capital. Most settlements were in the eastern part of the region, but the Indians made trips to the west to hunt buffalo.

After the first hard years, the Indians began to build schools and churches, clear land, and operate farms and ranches. They were protected from white settlement by their treaties, so the general westward movement of the pioneers passed them.

The Civil War (1861-1865) destroyed the prosperity and protection the Indians enjoyed. The Five Civilized Tribes had come from the South, and many of the Indians owned slaves. Delegations from Texas and Arkansas urged the Indians to join the Confederacy. In 1861, a Confederate military leader, Albert Pike, made treaties of alliance with some of the tribes. These tribes included some Plains Indians who had moved into the area. At first the Cherokee leader, Chief John Ross, tried to avoid taking sides. But after the Confederates won a battle near the Cherokee border, at Wilson's Creek in Missouri, Ross pledged the Cherokee to the South. Pike then recruited and led a brigade of Indians to fight for the South. One Cherokee, Stand Watie, became a Confederate brigadier general. Other Indians, however, fought for the Union.

After the Civil War, Congress forced the Five Civilized Tribes to give up the western part of their land because they had supported the South. Some of this land was given or sold to other Indian tribes.

The land that bordered the Indian Territory filled rapidly with settlers. Soon there was no more free or cheap land available. The whites wanted to use the fertile Indian lands. During the late 1860's, many cattlemen drove their herds across Oklahoma on their way from Texas to the Kansas railroad centers. Some cattle ranchers paid the Indians for grazing rights, but others did not. From 1866 to 1885, over 6 million longhorn cattle crossed the

Indian lands. The East Shawnee, West Shawnee, Chisholm, and Western trails were the leading routes. In 1883, an association of cattle ranchers leased more than 6 million acres (2.4 million hectares) from the Indians for five years. But the U.S. government declared all the leases invalid. President Benjamin Harrison ordered the whites' cattle removed in 1890.

The great land rushes. "Boomers" urged the government to open the land for white settlement. The boomer leaders included C. C. Carpenter, David L. Payne, and William L. Couch. Finally the government yielded. It bought over 3 million acres (1.2 million hectares) from the Creek and Seminole tribes. Authorities declared almost 1,900,000 acres (769,000 hectares) in central Oklahoma open for settlement at noon, April 22, 1889. Thousands of settlers moved to the border to await the opening. The army held them back until a pistol shot signaled the opening. Then a wild race began to claim the best farms and townsites. About 50,000 people had moved into Oklahoma by that evening. In a single day, Guthrie and Oklahoma City became cities of 10,000 persons.

Some settlers, called Sooners, went into the area before the opening to claim the best land. To hide their early entry, many Sooners ran their horses hard on the day of the opening. Then the tired horses would be shown to the pioneers who had followed the rules, to "prove" that the owner had just arrived.

The Territory of Oklahoma was established by Congress in May 1890, with Guthrie as the capital. The same act added the Panhandle to the territory. The Panhandle had become U.S. territory when Texas joined the Union in 1845. President Harrison appointed George W. Steele as the first territorial governor.

During the 1890's, more and more Indian tribes accepted individual *allotment* of their lands. This meant that individual Indians, not the tribe, owned the land. Land not allotted to tribe members was opened for settlement. In some areas, settlers got their land by *run,* or land rush. Other land was distributed by a lottery.

The greatest opening occurred on Sept. 16, 1893. That day, the Cherokee Outlet, in north-central Oklahoma, and the Tonkawa and Pawnee reservations were opened. Over 50,000 people claimed land in the $6\frac{1}{2}$ million-acre (2.6 million-hectare) area the first day.

Progress toward statehood. After 1890, maps showed the Oklahoma area as the Twin Territories— Indian Territory and Oklahoma Territory. Indian Territory was the remaining land of the Five Civilized Tribes, plus a small area owned and settled by other tribes. The rest of the region was Oklahoma Territory.

White settlers now wanted the remaining Indian lands. In 1893, Congress created the Dawes Commission to bargain for the land and to dissolve the Indian nations. Agents of the commission helped the tribes incorporate towns and prepare for citizenship. The commission divided the remaining land among members of the tribes. By 1905, commission leaders felt the Indian Territory was ready to become a state.

Leaders of the Five Civilized Tribes called a constitutional convention at Muskogee in 1905 and invited white citizens to take part. At the time, whites in the Indian Territory outnumbered the Indians five to one. The convention adopted a constitution for the proposed state of Sequoyah, and the people approved it in an election. But Congress refused to accept the area as a state. Congress wanted one state to be created from the Twin Territories. In 1906, delegates from both territories met in Guthrie to draw up a constitution.

Early statehood. On Nov. 16, 1907, Oklahoma became the 46th state in the Union. Charles N. Haskell of Muskogee was elected the first governor. The new state had a population of 1,414,177. Guthrie was the first capital. In 1910, Oklahoma City became the capital.

Even before statehood, Oklahoma had become a center of oil production. A small well was drilled near Chelsea in 1889. The first important well was drilled at Bartlesville in 1897. Tulsa became an oil center after the Red Fork-Tulsa field was opened in 1901.

But there were problems, especially among farmers. The prices of farm products were low, and many settlers found they did not have enough land to farm profitably. After the United States entered World War I in 1917, these problems disappeared in the huge demand for Oklahoma's farm and fuel products.

The 1920's. During the 1920's, many of Oklahoma's problems returned. Farm prices dropped again, and economic distress led to unrest. Secret organizations, such as the Ku Klux Klan, stirred into action (see **Ku Klux Klan**). The Klan won many members all over the state, and controlled or elected many municipal and county officials. But Governor James B. A. Robertson, who served from 1919 to 1923, fought the Klan and refused to allow any state official to join the organization.

In 1923, John C. Walton became governor. He was impeached for abusing his powers. The state legislature removed him from office after only 9 months and 14 days. Among other things, Walton had used the National Guard to prevent a grand jury from meeting. Lieutenant Governor Martin E. Trapp became governor and served until 1927. Trapp was a "hard roads" governor who pushed the construction of all-weather highways. Trapp also backed a law that made it illegal to wear masks at public gatherings. This law helped control the Klan. Henry S. Johnston became governor in 1927, but he, too, was impeached. After two years in office, Johnston was found guilty of incompetence and removed by the legislature. In March 1929, Lieutenant Governor William J. Holloway became governor.

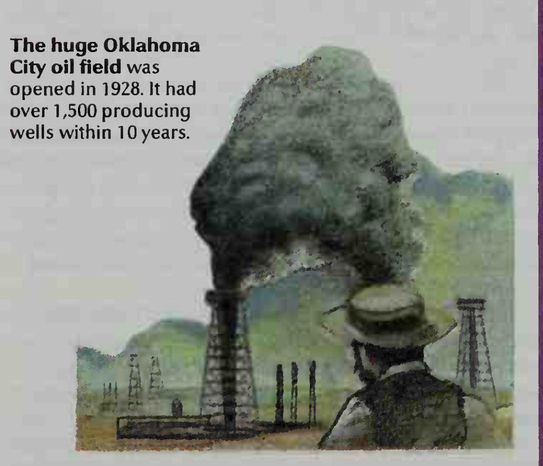
Important discoveries of oil and gas helped Oklahoma during this period. The huge Oklahoma City field was opened in 1928. It had more than 1,500 producing wells within 10 years. The Greater Seminole area led the nation in production from 1925 to 1929.

The 1930's. The campaign of 1930 was highlighted by the election as governor of one of Oklahoma's most colorful politicians, William H. "Alfalfa Bill" Murray. A former congressman, Murray appealed to the "common folks" to vote for him. After his election, Murray shut down over 3,000 flowing oil wells. The price of oil had been dropping, and Murray wanted to keep some oil off the market to force up the price. After three months, he permitted production to start again.

Oklahoma suffered many hardships during the Great Depression of the 1930's. Business was bad, and farm prices were extremely low. Many banks failed, and people lost their savings. The entire Great Plains region suffered a severe water shortage. Crops failed for lack of

Historic Oklahoma

The Butterfield stage line ran across Oklahoma on its route from St. Louis to San Francisco. It opened in 1858.



A forced relocation of thousands of Indians to Oklahoma from the Southeastern United States took place between 1830 and 1842.

The Chisholm Trail was used to drive millions of cattle across Oklahoma to Kansas during the 1870's.

The Dust Bowl formed in the 1930's, forcing many Oklahoma farmers to move elsewhere.

The huge Oklahoma City oil field was opened in 1928. It had over 1,500 producing wells within 10 years.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Oklahoma

1541 Francisco Vásquez de Coronado crossed western Oklahoma in a search for gold.

1682 Robert Cavelier, Sieur de La Salle, claimed Oklahoma as part of French Louisiana.

1762 France gave Louisiana, including the Oklahoma region, to Spain.

1800 France regained Louisiana.

1803 The United States bought the Oklahoma region, except the Panhandle, as part of the Louisiana Purchase.

1819 The Oklahoma region, except the Panhandle, became part of the Territory of Arkansas.

1824 The government established Fort Gibson and Fort Towson, the region's first military posts.

1830-1842 The Five Civilized Tribes moved to Oklahoma.

1870-1872 The Missouri-Kansas-Texas railroad was built across the region.

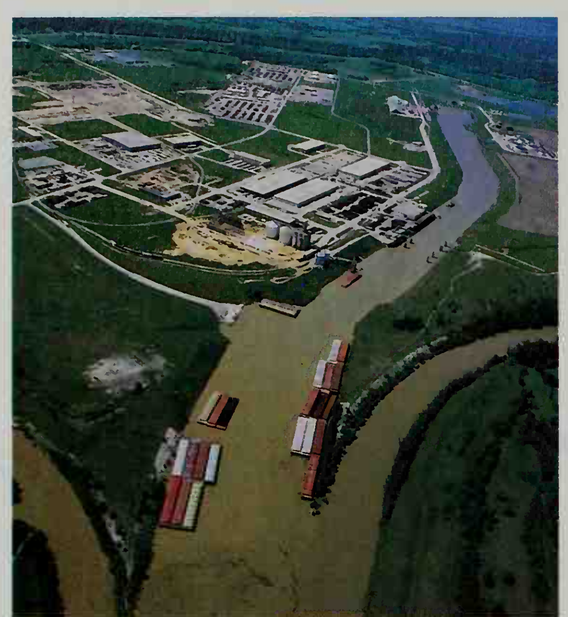
1872 Oklahoma's first commercial coal was mined near McAlester.

1889 The United States opened part of Oklahoma to white settlement. The region's first producing oil well was drilled near Chelsea.

1890 Congress established the Territory of Oklahoma and added the Panhandle region to it.

1893 Congress established the Dawes Commission to manage the affairs of the Five Civilized Tribes. The Cherokee Outlet was opened to white settlement.

1907 On November 16, Oklahoma became the 46th state to join the Union.



1920 The Osage County oil fields began to produce.

1928 The Oklahoma City oil field opened.

1963 Henry Bellmon became the first Republican governor of Oklahoma.

1990 Oklahoma became the first state to pass term limits on members of its state legislature.

1995 A terrorist bomb blew up a federal government building in Oklahoma City, killing 168 people.

Tulsa Port of Catoosa

Tulsa's port and a large industrial area are located at nearby Catoosa on the Verdigris River. Barges haul goods between this port, the busiest in Oklahoma, and Mississippi River ports.

rain, and there were unusually hot summers. High winds stripped away large areas of fertile topsoil and whipped the dry dirt into massive dust storms that turned day into night. Much of the plains area became known as the *Dust Bowl* (see **Dust Bowl**). Many farmers, miners, and oil workers left the state to try their luck elsewhere. Oklahoma suffered a large loss of population. See **Great Depression** (Human suffering).

The mid-1900's. During World War II (1939-1945), Oklahoma's major products—food and fuels—again came into great demand. Increased use of soil conservation practices helped restore many farms that had been damaged during the drought of the 1930's.

From 1943 to 1947, Governor Robert S. Kerr brought about reforms in education, state finances, and pardon and parole procedures for convicts. After serving his term as governor, Kerr won election to the United States Senate.

During the 1950's, Oklahoma's economy began to shift from an agricultural to an industrial base. Both the size and number of farms declined. Johnston Murray, the son of Alfalfa Bill Murray, became governor in 1951 and started a campaign to develop new industry in the state. His successor, Raymond D. Gary, continued Oklahoma's industrial expansion.

New industries and construction projects highlighted the state's economic progress during the 1960's. Two large electronics plants were built in Oklahoma City, and Tulsa became the site of a space equipment factory. The Federal Aviation Administration built an aeronautics center in Oklahoma City. This center trains workers for civil aviation jobs, such as that of control tower operator, and conducts research into airplane crashes. In 1963, Henry Bellmon became the state's first Republican governor.

Construction of a number of dams and creation of several lakes began in the mid-1900's. Some of these projects were completed in the 1960's, and others were finished in the 1970's. The lakes were created to increase the state's hydroelectric power and water storage capacities. The new dams and lakes assisted business and political leaders in their efforts to broaden the state's industrial activity. The state government advertised Oklahoma's abundant supplies of fuel, water, and electric power. In addition, the legislature revised the state's tax structure to attract manufacturers. As a result, Oklahoma gained new industries that do not depend on the products of its farms and mines.

The late 1900's. The McClellan-Kerr Arkansas River Navigation System, completed in 1970, made shipping an important activity. The waterway enables barges on the Mississippi River to reach Oklahoma ports on the Arkansas River. Tulsa and Muskogee are important ports on the river system.

Between 1976 and 1980, a strong world demand for energy led to an economic boom in Oklahoma. The state's petroleum and natural gas industries thrived and brought much income to Oklahoma. In addition, rising tourism contributed to the state's economy.

During the early 1980's, however, the prices of oil and gas fell sharply, and the economic boom in the state ended. In addition, a deep decline in agricultural prices helped bring on an economic crisis for thousands of Oklahomans. Hundreds of oil wells shut down, and many farmers lost their farms. The reduction in tax revenue from oil and gas production also led to cuts in public services. Unemployment increased rapidly, and many people left the state in search of jobs.

The economic crisis helped focus attention on the need to further broaden the state's economy. Once again, state leaders emphasized the need to attract new industries that would help lessen Oklahoma's dependence on its traditional mineral and agricultural industries.

In 1982, betting on horse races became legal in Oklahoma. The sale of alcoholic beverages had become illegal in Oklahoma in 1907. In 1959, the state had repealed this prohibition, with certain limitations. Selling beverages of more than 3.2 percent alcohol by the glass remained illegal in such public places as bars and restaurants. In 1984, the state gave each county the right to decide whether to end the restrictions on alcoholic beverage sales within its borders.

In 1990, Oklahomans voted to limit state legislators to no more than 12 total years of elective service. This was the first time any state's voters passed such term limits.

In 1995, a terrorist bomb blew up Oklahoma City's Murrah Federal Building, killing 168 people. The incident was one of the worst terrorist acts in the United States. For details on it, see **Oklahoma City** (History).

Oklahoma, University of, is a state-supported coeducational institution in Norman, Oklahoma. It has colleges of architecture, arts and sciences, business administration, education, engineering, fine arts, geosciences, law, and liberal studies; and a graduate college. The Health Sciences Center, in Oklahoma City, has colleges of allied health, dentistry, medicine, nursing, pharmacy, and public health. The college of medicine also has a branch in Tulsa. The university grants bachelor's, master's, and doctor's degrees.

Research facilities on the Norman campus include the Center for the Analysis and Prediction of Storms and the Carl Albert Congressional Research Center. The Molecular Medicine Research Center is in Oklahoma City. The University of Oklahoma Press publishes a wide range of scholarly books. The university was founded in 1890.

Critically reviewed by the University of Oklahoma

Oklahoma City (pop. 506,132; met. area pop. 1,083,346) is the capital and largest city of Oklahoma. About 30 percent of the state's people live in the Oklahoma City metropolitan area. The city ranks as one of the chief centers of oil production in the United States. It is a commercial and manufacturing center of Oklahoma and a distribution point for a large farming area.

Oklahoma City lies on the North Canadian River, near the geographic center of the state. For location, see **Oklahoma** (political map). White settlers first came to what is now the Oklahoma City area in 1889. The United States government had originally set this land aside for Indians. But the government later opened central Oklahoma for white settlement. On the first day, about 10,000 settlers flocked to a site near the Atchison, Topeka and Santa Fe (now part of the Burlington Northern Santa Fe Corporation) Railway tracks and pitched their tents. This settlement became Oklahoma City. The city's name came from two Choctaw Indian words—*okla,* meaning *people,* and *homma,* meaning *red.*

The city covers 647 square miles (1,676 square kilometers), including 14 square miles (36 square kilometers) of inland water. The Oklahoma City metropolitan area consists of six counties—Canadian, Cleveland, Logan, McClain, Oklahoma, and Pottawatomie—and covers an area of about 4,303 square miles (11,145 square kilometers).

The State Capitol stands in a major oil field near the heart of the city. A statue called *The Cowboy* stands in front of the Capitol (see **Oklahoma** [picture: The State Capitol]). A well on the Capitol grounds that was drilled to draw oil from beneath the Capitol was long a tourist attraction. It ended production in 1986. Other producing wells are scattered throughout the city.

The city's Myriad Convention Center is one of the leading convention sites in the United States. The 36-story Liberty Bank Tower is the city's tallest building.

About 97 percent of the city's people were born in the United States. African Americans make up about 15 percent of the city's population. About 10 percent of the people are Hispanics, 4 percent are American Indians, and 3 percent are Asians.

Economy. The leading industries of Oklahoma City produce automobile assemblies, construction equipment, electronic equipment, food products, and petroleum products. Other Oklahoma City products include building materials, cottonseed oil, iron and steel products, paper products, telephone equipment, and transportation equipment. About 1,200 manufacturing plants employ 10 percent of the city's workers.

The federal and state governments employ about 20 percent of Oklahoma City's work force. Tinker Air Force Base is the largest single employer. This important repair and supply station for the U.S. Air Force employs about 18,000 civilians. The Federal Aviation Administration has about 3,000 civilian employees in the city.

Much of Oklahoma City's industrial importance results from its location in an area rich in natural resources for both oil production and farming. The area in Oklahoma County has about 980 oil wells and about 200 wells that produce natural gas. The city processes and distributes such farm products as feed, flour, and meat. It is the nation's leading cattle market.

Will Rogers World Airport lies in the southwestern part of the city. Buses, trucks, and freight and passenger trains also serve the city. Oklahoma City has one daily newspaper, *The Daily Oklahoman.*

Education and cultural life. Oklahoma City's public school system includes about 65 elementary schools and more than 20 high schools. The city also has about 30 church-supported and private schools. Colleges and universities in Oklahoma City include Mid-America Bible College, Oklahoma Christian University, Oklahoma City University, and the University of Oklahoma Health Sciences Center. The University of Oklahoma is in nearby Norman. Southern Nazarene University is in nearby Bethany. The University of Central Oklahoma is just north of Oklahoma City, in Edmond. The city's library system consists of a main library and 10 branches.

Oklahoma City has several community theaters. The Oklahoma City Philharmonic Orchestra performs at the Civic Center Music Hall. The National Cowboy & Western Heritage Museum displays paintings and sculptures of the American West. The Oklahoma Museum of Art features European and American paintings and sculptures. The Oklahoma Art Center offers contemporary works by regional and national artists.

The Oklahoma Historical Society Building and Museum has a collection of exhibits tracing the history of Oklahoma. The Kirkpatrick Science and Air Space Museum at Omniplex includes the Hands-On Science Museum, the Kirkpatrick Planetarium, the Air Space Museum, the Kirkpatrick Galleries, and the Kirkpatrick Gardens and Greenhouse. The Omniplex also houses the International Photography Hall of Fame and Museum and the Red Earth Indian Center.

Oklahoma City has 144 parks, which cover about 4,000 acres (1,600 hectares). Lincoln Park, the largest, occupies 632 acres (256 hectares) and includes the Oklahoma City Zoo.

Government. Oklahoma City has a council-manager form of government. The voters elect a mayor and eight council members to four-year terms. The council appoints a city manager.

In 1971, the voters elected Patience S. Latting mayor. She became the first woman mayor of a United States city of more than 200,000 people. Sales taxes provide most of the city's revenue.

History. Creek and Seminole Indians lived in what is now the Oklahoma City area before white settlers first arrived. In 1889, the government bought the land there from the two tribes. On April 22, 1889, the government opened the area for white settlement, and a great land rush began. By the evening of that day, about 10,000 settlers had arrived there. Oklahoma City was incorporated in 1890. By 1910, it was the state's largest city. Its popula-

Randy Bennett, Oklahoma City Public Information Office

Oklahoma City is the capital and largest city of Oklahoma. Its downtown area, *shown here,* includes towering office buildings and hotels. Some of the buildings were constructed as part of a renewal program that began in the mid-1900's.

AP/Wide World

A terrorist bomb destroyed Oklahoma City's Murrah Federal Building, *shown here,* on April 19, 1995. The bomb killed 168 people, including 19 children. After a long search for victims, the building was razed.

tion rose from 10,037 in 1900 to 64,205 in 1910. During that period, four railroads began to serve the city and two meat-packing plants opened. In 1910, Oklahoma City replaced Guthrie as the state capital.

The city's greatest problem during its early years was a lack of water sources. Shortly after 1900, Oklahoma City built its first municipal well. In 1919, it completed its first reservoir, Lake Overholser. Since then, the city has built several more reservoirs.

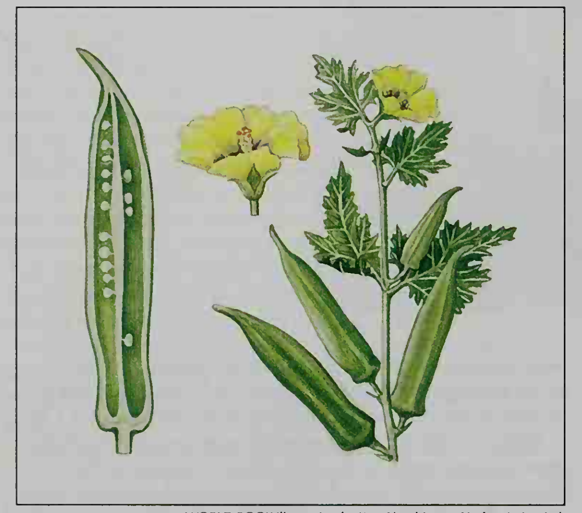
By 1920, Oklahoma City had 91,295 people. Oil was discovered in the city in 1928, and an oil boom began. Many oil companies built refineries, and the area became a center of the nation's petroleum industry.

Tinker Air Force Base was built in Oklahoma City during World War II (1939-1945). By 1950, the population of the city had risen to 243,504.

Industrial expansion occurred during the 1950's and 1960's. Iron and steel plants were built, and the city also became a center of the electronics industry. Development also took place in downtown Oklahoma City. During the 1960's, the city annexed many surrounding areas, and its area increased from about 310 square miles (803 square kilometers) in 1960 to about 635 square miles (1,645 square kilometers) in 1970. Oklahoma City's population continued to grow. It reached 403,484 by 1980.

Since the late 1960's, Oklahoma City has undertaken several urban renewal projects to replace old buildings and wipe out slums. One of the projects, called the Medical Center Project, was completed in 1978. It includes a dental college, a hospital, a nursing school, and headquarters for the State Health Department.

The Central Business District Project, which included the construction of several office buildings and a convention center, was completed in 1985. The John F. Kennedy Project involved renovating or replacing 1,260 acres (510 hectares) of slum housing. It was completed in 1988. A race track opened in northeast Oklahoma City in 1988. In 1998, a 13,000-seat minor league baseball stadium was completed. Further redevelopment of the downtown area is scheduled for completion in the early 2000's. Projects include construction of a 20,000-seat arena, development along the North Canadian River, a new library, and construction of a civic center and music hall.



On April 19, 1995, Oklahoma City became the site of one of the worst terrorist acts in the United States. One or more terrorists put a bomb in a truck in front of the Alfred P. Murrah Federal Building in the downtown area and set off the bomb. The explosion destroyed the building and killed 168 people. The victims included 19 children, most of whom were at a day-care center in the building. Timothy J. McVeigh and Terry L. Nichols, both American citizens, were arrested and charged with the crime. The charges said both men made the bomb, and that McVeigh brought the truck to the building and set off the bomb. Earlier, McVeigh and Nichols had expressed strong opposition to the federal government. A third American citizen, Michael Fortier, was charged with aiding McVeigh and Nichols. He pleaded guilty, agreed to be a witness in the trials of the two other men, and was sentenced to 23 years in prison. McVeigh was convicted and sentenced to death. He was executed on June 11, 2001. Nichols was convicted and sentenced to life in prison without parole. The Oklahoma City National Memorial, on the site of the destroyed building, was dedicated in 2000. Ed Kelley

See Oklahoma (Climate; pictures).

Oklahoma State University is a state-funded coeducational school in Stillwater, Oklahoma. It has colleges

of agriculture, arts and sciences, business administration, education, engineering, home economics, veterinary medicine, and a graduate college. It also offers a program in fire protection and safety technology. The school grants bachelor's, master's, and doctor's degrees. It has a two-year technical branch in Okmulgee and one in Oklahoma City and a college of osteopathic medicine in Tulsa. It also offers programs at the university center at Tulsa. The university maintains a number of agricultural experiment stations and a state extension service. It also has Army and Air Force ROTC units. The university was established in 1890 and was opened to students in 1891. Critically reviewed by Oklahoma State University

Okra, *OH kruh,* also called *gumbo* or *okro,* is a plant cultivated for its immature pods. The pods are eaten as a vegetable chiefly in the southern part of the United States. They are typically fried or used as an ingredient in stews or soups.

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd.

Okra is a tall plant raised for its sticky green pods, which are used in cooking. The plant bears greenish-yellow flowers.

The okra plant is an *annual* and must be raised from seed each year. Gardeners plant the seeds in the spring. The okra plant grows 2 to 8 feet (0.6 to 2.4 meters) high. It bears rounded, fine-lobed leaves, and greenish-yellow flowers. The pods on the plant measure from 4 to 6 inches (10 to 15 centimeters) long. However, they sometimes exceed 1 foot (30 centimeters) when fully grown. Okra pods are cooked and canned when they are young and tender.

Okra is a kind of hibiscus and is related to cotton. It is a native of Africa. Okra is raised in large quantities in the southern United States. S. J. Locascio

Scientific classification. Okra is a member of the mallow family, Malvaceae. Okra is *Hibiscus esculentus.*

Olajuwon, *oh LY juh wahn,* **Hakeem,** *ah KEEM* (1963-), ranks among the greatest centers in the history of the National Basketball Association (NBA). Olajuwon stands 7 feet (213 centimeters) tall. On offense, he is known for his quick, graceful moves and accurate jump shot. Defensively, he is one of the leading shot-blockers in NBA history. Olajuwon led the Houston Rockets to the NBA championship in 1993-1994 and again in 1994-1995. During the 1993-1994 season, he became the first NBA player ever to be named the league's Most Valuable Player, defensive player of the year, and Most Valuable Player in the play-off finals in the same season.

Hakeem Abdul Olajuwon was born in Lagos, Nigeria. He played soccer and handball as well as basketball in Nigeria. He attended the University of Houston from 1981 to 1984, where he was a star player. The Houston Rockets selected him as the first player in the 1984 draft. Houston traded him to the Toronto Raptors after the 2000-2001 season. Early in his career, his name was spelled *Akeem.* He then changed it to *Hakeem.* Olajuwon became a U.S. citizen in 1993. Sam Smith

Old age cannot be defined exactly because it does not have the same meaning in all societies. In many parts of the world, people are considered old because of certain changes in their activities or social roles. For example, people may be considered old when they become grandparents or when they begin to do less or different work. In the United States, people are often considered old if they have lived a certain number of years. Many Americans think of 65 as the beginning of old age because United States workers become eligible to retire with full social security benefits at age 65. People in the 65-and-over age group are often called *senior citizens.* Starting in the year 2003, the age at which a person becomes eligible for full social security benefits will increase gradually until it reaches age 67 in 2027.

Worldwide, the number of people 65 or older is increasing faster than ever before. Most of this increase is occurring in developing countries. In the United States, the percentage of people 65 or older increased from 4 percent in 1900 to about 13 percent in the late 1990's. In 1900, only about 3 million of the nation's people had reached 65. By 1998, the number of senior citizens had increased to about 34 million. Population experts estimate that more than 50 million Americans—about 17 percent of the population—will be 65 or older in 2020. The number of elderly people is growing around the world chiefly because more children reach adulthood.

In most parts of the world, women live, on average, longer than men. In the United States in the late 1990's, life expectancy at birth was 80 years for women and 73 years for men. American women who were age 65 in the late 1990's could expect to live about 19 additional years. Men who were 65 could expect to live about 16 additional years.

The study of aging and old age is called *gerontology.* Many universities and colleges offer courses in gerontology for people who wish to provide services for the elderly. *Geriatrics* is the branch of medicine that deals with old age and its diseases. Most medical schools offer courses in geriatrics.

The rest of this article mainly discusses attitudes toward old age and tells about ways of life of the elderly in the United States. For information on the medical and physical aspects of old age, see the *World Book* articles on **Aging** and **Geriatrics**.

Attitudes toward old age

In all societies, old people are generally more respected if they control important resources, such as information, money, or land. In many countries, for exam-

ple, the ability of the elderly to provide information based on their extensive experience gives them a respected position in society. This is particularly true in nonindustrial countries, which have few books or computers to store information. In modern industrial nations, however, many people do not regard the elderly as wiser or more knowledgeable. Also in industrial nations, where income from work is a major resource and where having a job earns a person respect, people may lose status when they retire.

Many beliefs about older people are untrue. Some employers, for example, think that younger workers are more efficient and reliable than older ones. But in many types of jobs, older people are better workers than younger people. The ideas that people become less intelligent as they age and that old people cannot learn new skills are also not true. Some researchers have called the many incorrect ideas about old people *ageism.*

Ways of life of the elderly

Older people in the United States follow many different ways of life. How a particular older person lives has much to do with how that person lived in earlier years. Important factors include the financial resources the person has accumulated, the interests the person has developed, and the relationships the person has established with other people.

Finances. The most important source of income for many retired workers is Social Security. Workers and their employers pay equal shares of a payroll tax into the Social Security fund, which is administered by the federal government. After the workers retire, they receive a monthly payment from the fund. The amount of their payment is determined by the salary they earned and the number of years they worked. Widows and widowers continue to receive the pension after the death of their spouses. See **Social security.**

Some retired people also receive a pension from their employer or have their own savings. Most retired people receive less than half as much as they earned while working. But in many cases, their expenses are also lower.

Employment and other activities. The majority of Americans over 65 do not have a job. Only about 15 percent of the men above this age and 8 percent of the women are employed. Under United States law, workers in most jobs cannot be forced to retire because of their age. However, even when employers were still allowed to enforce a retirement age, most people stopped working for other reasons. Health and expected retirement income were, and still are, the chief factors in the decision to retire.

Some senior citizens join private groups for social and recreational activities. These groups include church organizations and senior citizens' clubs. Some elderly people join AARP (formerly the American Association of Retired Persons), the National Council of Senior Citizens, or similar organizations. These groups offer a large number of services, including educational and travel programs, medical insurance, and newsletters. In addition, such organizations also tell politicians about older people's views on medical care, Social Security, and related issues. An organization called the Gray Panthers, whose members include both young and old, works to fight ageism in U.S. society.

The U.S. government provides several programs that enable senior citizens to help other people. For example, the Service Corps of Retired Executives (SCORE) attracts retired business people who enjoy advising community organizations and small businesses. The Foster Grandparent Program (FGP) uses seniors to help care for children. People over 60 may also join the Retired Senior Volunteer Program (RSVP) to work in hospitals, libraries, schools, and other institutions.

Older people seem to have a greater involvement in politics than do members of any other age group in the United States. A higher percentage of elderly people than other individuals vote in elections.

Housing. Most Americans over 65 are closely involved with their families. However, only about one-eighth of all elderly Americans live with a relative other than their husband or wife. A large number of elderly parents and their children prefer the independence and privacy of living in separate dwellings. In other countries, the percentage of elderly parents who live with their children is much higher. In Japan, for example, about two-thirds of all elderly parents live with one of their children.

In the United States, only about 5 percent of the elderly live in a nursing home or other institution. Some of the senior citizens in the United States live in special housing called *retirement communities.* These communities may consist of apartment buildings, individual houses, or groups of mobile homes. In retirement communities, residents are guaranteed medical care for as long as they live.

Health care. The federal government administers Medicare, a medical insurance program for senior citizens that pays part of their expenses for physicians and hospital care. Medicare also pays a portion of the cost of medical services at home or in a nursing home. However, medical expenses remain a serious problem for many older people and their families, especially if long-term care is needed because of a chronic illness. Finding ways for older people to receive high-quality, long-term care is a major problem facing American policymakers today. See **Medicare.** Jennie Keith

Old Bailey is the common name for the Central Criminal Court in London. The Old Bailey has several courts, and each one holds sessions at least four times a year. It

is located on a street called Old Bailey. This street once formed part of a *bailey* (an area between the inner and outer city walls) in medieval London.

The city government built the Sessions House in 1550. This building became known as the Old Bailey. People held at nearby Newgate Prison were tried in the Old Bailey (see **Newgate Prison**). Famous cases held there included the treason trial of judges responsible for the execution of King Charles I; the treason trial of William Joyce, who broadcast for Nazi Germany during World War II as *Lord Haw Haw;* and the morals trial of the author and playwright Oscar Wilde. Robert E. Dowse

Old Catholic churches are a group of Christian churches that split away from the Roman Catholic Church. Most of them were formed by Catholics who opposed the dogma of *papal infallibility* proclaimed at the first Vatican Council in 1870. This dogma states that the pope is free from error when he speaks as head of the church on matters of faith and morals.

The Catholics who withdrew from the Roman Catholic Church at that time established an independent church. Most of these Catholics lived in Germany, the Netherlands, Switzerland, and the Austro-Hungarian Empire. In 1889, the independent church formed a loose relationship with other dissenting Catholic churches under the terms of an agreement called the Union of Utrecht. Some of these dissenting churches had been established as early as 1724.

Old Catholic churches generally follow Roman Catholic doctrine, though the clergy may marry. The churches encourage Bible study. Marvin R. O'Connell

Old English sheepdog is best known for its long hair, "bobbed" tail, and odd, shuffling walk. Its hair hangs down over its eyes. Much brushing is required to keep the dog's long coat neat. The coat serves as excellent insulation. It is gray or blue, often with white markings, or mostly white with gray or blue markings. The dog stands about 22 inches (56 centimeters) high, and weighs from 50 to 65 pounds (23 to 29 kilograms).

Old North Church is the popular name for Christ Church, which is the oldest public building in Boston. The red-brick structure has a slender white steeple in the Christopher Wren style. Robert Newman hung the lanterns there as a signal from Paul Revere that the British were coming. The tower contains the first set of church bells in the American Colonies, cast in 1744. Storms in 1804 and 1954 toppled the spire. In 1955, it was rebuilt to its original height of 190 feet (58 meters).

Old Testament is the Christian name for the Jewish Bible. Judaism accepts only the Old Testament as its Bible. Thus, when Jews use the term Bible they mean only those books in the Old Testament. When Christians refer to the Bible, they mean the larger collection that includes the Old Testament and the later New Testament.

Many scholars have replaced the term *Old Testament* with more neutral names. Two such names are the *Hebrew Bible* and *Tanakh,* a word composed of the first letters of three Hebrew words—*Torah, Nebiim,* and *Ketubim.* These Hebrew words are the names of the three sections of the Hebrew Bible. Of all the possible terms, Old Testament and Hebrew Bible are most often used interchangeably.

The Old Testament emphasizes the idea of a *covenant* (solemn agreement) between God and the Israelite people. The covenant is based on a belief in God. In the agreement, God promises to reward the people if they observe its conditions and laws and to punish them if they violate its terms. These aspects of the covenant resemble actual historical agreements between ancient kings and the countries they conquered. Much of the Old Testament traces the history of the Israelites to show how well they observed the covenant and how God treated them as a result.

Contents. The contents of both the Jewish and Christian Bibles changed over many centuries. All Christian Old Testaments are still not identical. The Greek Jewish Bible adopted by early Christianity differed from the Hebrew Bible adopted by Judaism. As a result, the Hebrew Bible is not identical in its contents to Christian Old Testaments. In addition, there are many different translations of the Old Testament. There are more Protestant translations than Roman Catholic translations.

The Old Testament accepted by Judaism consists of 24

Vic Bider, The Stock Market

The graceful steeple of historic Old North Church pierces the skyline near the business district of Boston.

books. Protestants accept the same books but arrange them differently. Protestants also divide several of the books, increasing the number to 39.

The Roman Catholic Old Testament includes an additional seven books that Protestants consider part of a collection of religious writings called the *Apocrypha*. Christian and Jewish groups differ in the position of importance they assign to the books of the Apocrypha. Many of these books resemble the Old Testament in form, but they were written later. This article discusses the Old Testament that is shared by the Jewish, Protestant, and Roman Catholic traditions.

The Hebrew Bible is divided into three main sections: the Law, also called the Torah or Pentateuch; the Prophets, or Nebiim; and the Writings, or Ketubim. The Christian Old Testament is divided into the Law, or Pentateuch; Historical Books; Wisdom Books; and Prophets. Both Jewish and Christian Bibles accept the books of Genesis, Exodus, Leviticus, Numbers, and Deuteronomy as the Law, but sometimes call it by different names.

The Jewish and Christian versions differ on the titles and arrangement of many of the other books. For example, the Hebrew Bible puts Joshua, Judges, Samuel, and Kings in the section called the Prophets, because the books describe the lives and activities of many prophets, including Elijah. The Christian Old Testament classifies these books as Historical Books, because they trace the early history of the Jewish people from the time they settled in Canaan during the 1200's B.C. until the Babylonians conquered the kingdom of Judah in 587 or 586 B.C.

Today, all Bibles also divide Samuel, Kings and Chronicles into two books each: 1 and 2 Samuel, 1 and 2 Kings, and 1 and 2 Chronicles. For a table of the books recognized by Jews, Protestants, and Catholics, see **Bible**.

Development. The Old Testament was written over a long period. The process was complicated, because much of the material was recited or chanted before it was written down. Scholars disagree about how and when the books were actually written.

The Old Testament's most detailed description of the production of a Biblical book (presumably Jeremiah) appears in chapter 36 of Jeremiah. This passage describes a process that included oral recitations by the prophet and the recording of his prophecies by his secretary. After the king of Judah cut up and burned the scroll, the secretary recorded it again from Jeremiah's memory and added several supplements. Though the Bible does not provide such complete descriptions of the other books, scholars assume that similar processes and stages of editorial activity contributed to their production.

Many parts of the historical and prophetic books were written during the kingdoms of Israel and Judah, from 922 to 586 B.C. Some of the most important prophets and poets lived during the Babylonian Exile, a period of captivity following Babylon's conquest of Judah in 587 or 586 B.C. Many traditions, laws, and historical records were collected and organized at that time. Other books were written after the exile ended in 538 B.C., when many Jews were allowed to return to Palestine.

The Dead Sea Scrolls show that the text of the Hebrew Bible in use today existed over 2,000 years ago. These scrolls include manuscripts of the Hebrew and Greek books of the Old Testament found in caves near the Dead Sea. They date from the 200's B.C. to A.D. 135.

Translations. The entire Old Testament was written in Hebrew, except for some chapters in the books of Daniel and Ezra and a few words in Genesis and Jeremiah. These passages are in Aramaic, a language much like Hebrew. The first translations were oral translations from Hebrew into Aramaic called *Targums*. In congregations that spoke Aramaic rather than Hebrew, a translator would stand beside the Bible reader in the synagogue and recite Hebrew passages in Aramaic verse by verse as the Bible was read.

In the 200's B.C., Jewish scholars working in Alexandria, Egypt, translated the Torah into Greek. Gradually other sections were added. The complete Greek translation is called the Septuagint.

Other translations of Old Testament books followed. The best-known Latin translation was the *Vulgate*, completed by Saint Jerome in A.D. 405. Jerome's translation was the official Old Testament text of the Roman Catholic Church for centuries. B. Barry Levy

Old World is a general term applied to the Eastern Hemisphere. The Old World includes the continents of Europe, Asia, Africa, and Australia. But the term *Old World* is often used to refer just to Europe or to European civilization. See also **New World; Hemisphere**.

Oldenburg, Claes, *klaws* (1929-), is an American sculptor who became a leader of the pop art movement during the early 1960's. He is known for his exaggerated, oversized sculptures that represent such familiar objects as ice cream cones, electric plugs, lipstick tubes, and Mickey Mouse.

Using these objects as the single subjects of his works, Oldenburg has created two principal types of sculpture. One of these types consists of sculptures that are made of soft material, thus contradicting the hardness of the actual objects. This soft material is frequently in a bright color that is related to its subject. The second type is made up of huge steel monuments of common objects designed to be placed in landscapes or among buildings (see **Des Moines** [picture]). By creating these caricatures of everyday objects, Oldenburg changes recognizable objects into abstract forms.

Oldenburg was born in Stockholm, Sweden. He be-

Enameled burlap and plaster (1962); The Museum of Modern Art, New York City, Philip Johnson Fund

Oldenburg's *Two Cheeseburgers with Everything* illustrates his use of soft materials to depict familiar objects.

came a United States citizen in 1953. Oldenburg is also noted for excellent preparatory drawings for his sculptures and for prints of his sculpture subjects.

Oldfield, Barney (1877-1946), was the first person to drive an automobile at a speed of 1 mile (1.6 kilometers) per minute. His name became synonymous with speed after he did this in a much-publicized test at Indianapolis on June 15, 1903. His first racing car, the "999," was built by Henry Ford. In it, Oldfield won his first race at Detroit in 1902. In 1910, at Daytona Beach, Florida, he raced a mile at an average speed of 131 miles per hour (211 kilometers per hour), a record then. Berner Eli Oldfield was born in Wauseon, Ohio. Sylvia Wilkinson

See also Aviation (picture: Airplanes raced against automobiles).

Olds, Ransom Eli (1864-1950), was a pioneer automobile inventor and manufacturer. Two automobiles, the Oldsmobile and the Reo (from his initials), were named for him.

Olds was born in Geneva, Ohio. In 1886, he began experimenting with steam-powered carriages in his father's machine shop in Lansing, Michigan. He later made a four-wheeled steam car that he sold to a firm in India in 1893. It was the first car manufactured in the United States that was sold abroad.

Olds built his first gasoline-powered car in 1896. In 1899, he helped found the Olds Motor Works in Detroit. A lightweight, one-cylinder, low-cost model ($650) was in volume production by 1901. Many thousands of these cars were sold by 1906.

In 1904, Olds left the Olds Motor Works and set up a firm to make Reo cars and trucks. He was president of the Reo Motor Car Company from 1904 to 1924 and later became its chairman.

Many people consider Olds to be the founder of the automobile industry. He built the first automobile factory that used the assembly line manufacturing process. In addition, the success of the Oldsmobile attracted other car manufacturers into the industry and helped make the automobile popular with Americans.

Oleander, *OH lee AN duhr,* is a popular ornamental flowering shrub. The oleander sometimes grows 15 feet (4.6 meters) tall. It has leathery, lance-shaped leaves and colorful roselike flowers. The two most common varieties have red and white blossoms. The oleander is native to the warm parts of Asia and to the Mediterranean region. Gardeners plant the oleander outdoors in warm climates. However, they grow it indoors in pots and tubs in temperate regions. It is a favorite porch plant in summer.

Gardeners raise the oleander from cuttings. When the cuttings are placed in bottles of water, they will form roots in a few weeks. After the cuttings root, they must be transplanted to moist, rich soil, where they grow well. All parts of the oleander are poisonous to eat.

Walter S. Judd

Scientific classification. The oleander is in the dogbane family, Apocynaceae. Its scientific name is *Nerium oleander.*

O'Leary, Hazel Rollins (1937-), served as the United States secretary of energy under President Bill Clinton from 1993 to 1997. She was the first woman and the first African American to hold that post.

Before O'Leary became secretary, she worked for the U.S. Federal Energy Administration and the Department of Energy under Presidents Gerald Ford and Jimmy Carter. In these positions, she was responsible for federal government programs designed to conserve energy and protect the environment. From 1989 to 1993, O'Leary was an executive of the Northern States Power Company, a utility based in Minneapolis, Minnesota.

O'Leary was born Hazel Reid in Newport News, Virginia. She earned a bachelor's degree from Fisk University in 1959 and a law degree from Rutgers University in 1966. Barbara A. Reynolds

Olefin is a manufactured fiber used widely in the production of carpeting and rugs and of thermal apparel, such as jackets and undergarments. The fiber consists of long, chainlike molecules called *polymers* that are at least 85 percent *olefin units* by weight. The most common olefin units are polypropylene and polyethylene. Olefin fibers are resilient, lightweight, and resistant to mildew and many chemicals.

Olefin polymers are produced by combining carbon and hydrogen under heat and pressure in the presence of a solvent and a *catalyst,* a substance that speeds chemical reactions. In the most common method of olefin fiber production, the polymer is melted and *extruded* (forced through a shaped die), then cooled and spun. Richard V. Gregory

Oligarchy, *AHL uh GAHR kee,* is any type of government in which power is held by relatively few people. An oligarchy may take many different forms. For exam-

WORLD BOOK illustration by Christabel King

The oleander is an ornamental flowering shrub. It produces leathery, lance-shaped leaves and colorful roselike blossoms.

ple, a republic may be an oligarchy if only a few people have the right to vote (see **Republic**). An aristocracy, in which rulers come from the "best" members of the community, is also a form of oligarchy (see **Aristocracy**). In most oligarchies, the ruling group has power because of its wealth or military authority.

The term *oligarchy* traditionally has been seen as the rule of a selfish few over a whole community. However, some political scientists apply the term to all forms of political and social organization, including states, political parties, churches, and corporations.

Oligarchies have existed throughout history. Most ancient Greek city-states were classic examples. In modern times, a number of military dictatorships in Africa, Asia, and Latin America have operated like oligarchies.

Alexander J. Groth

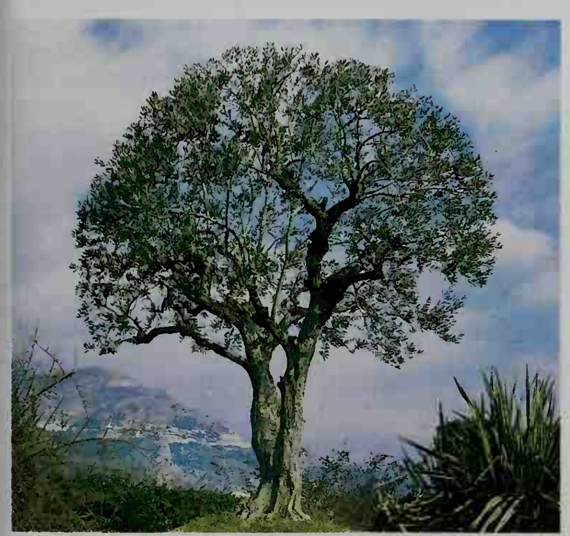
Oligocene Epoch. See Earth (table: Outline of the earth's history).

Oligopoly. See **Monopoly and competition**.

Oliphant, *AHL ih fuhnt,* **Patrick Bruce** (1935-), is a well-known editorial cartoonist. The figures in his cartoons have very exaggerated features, and his work is more biting than that of most other editorial cartoonists. Most Oliphant cartoons include Punk the Penguin, a character that usually comments on the action in the drawings. Oliphant won the Pulitzer Prize for cartooning in 1967.

Oliphant was born in Adelaide, Australia. In 1955, he became the editorial cartoonist of *The Advertiser,* the Adelaide newspaper. He came to the United States in 1964 to join the *Denver Post* as editorial cartoonist. From 1975 to 1981, he worked on *The Washington Star.* Universal Press Syndicate distributes Oliphant's cartoons to about 500 newspapers. Collections of his work have been published in *The Oliphant Book* (1969) and *Four More Years* (1973). Roy Paul Nelson

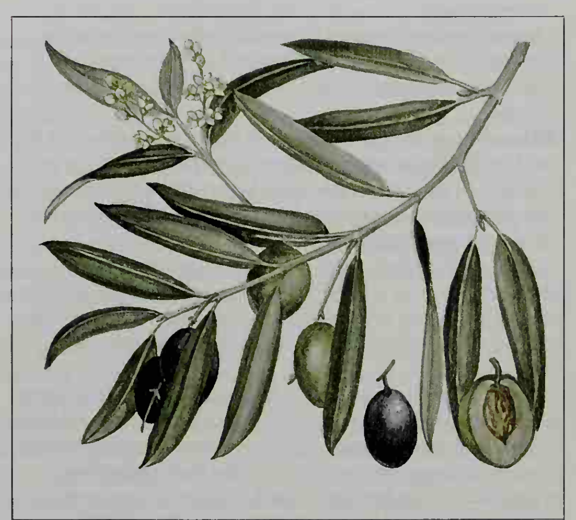
Olive is the fruit of a tree that grows in subtropical regions. Olives are cultivated chiefly for their oil, which is used in cooking. The fruit is also eaten whole after processing. People have grown olives since prehistoric times. It is thought that the fruit first grew in the eastern Mediterranean basin. Centuries ago, it began to grow wild around the Mediterranean Sea. The Spaniards brought olives to South America, and they were introduced into California in 1769.



Appearance of the fruit and tree. The fruit may be oval or oblong. As it matures, it turns from green to yellow to red to purple-black. It has a smooth skin, and its flesh surrounds a hard pit. Both the flesh and the seed in the pit contain oil, which makes up 10 to 40 percent of the mature fresh fruit's weight. Fresh olives contain *oleuropein,* a bitter substance that makes them unpleasant to eat before processing. During processing, this substance is largely or entirely removed.

The olive tree's bark and leaves are a soft gray-green, and its trunk becomes gnarled as it ages. Olive trees live longer than most other fruit trees. There are olive trees in Palestine that may be more than 2,000 years old.

A mature olive tree may have as many as 500,000 small flowers. Most of the flowers are imperfect, and fruit cannot grow from them. They give off pollen, which is usually carried from flower to flower by the wind. Most varieties of olive trees bear a large crop one season and a small crop the next.



Cultivation. Parts cut off from an olive tree may take root and grow into new trees. The trees will grow in many types of soil but need good drainage. To produce large fruit, the grower must irrigate and prune the trees, and thin the fruit. Fertilizers that add nitrogen to the soil can increase yields. The olive tree will grow where the climate is hot and dry. But for bearing good fruit, the tree needs a moderate supply of water. The fruit matures from October to January and is injured if the temperature falls below 26 °F (−3 °C). The tree itself is not seriously injured until the temperature falls to 16 °F (−9 °C). The fruit needs much heat to have a good quality when mature. The air must be dry when the flowers blossom, and also when the fruit begins to grow.

Harvesting and preparation for market. Most olive-producing nations grow the fruit primarily for its

Olives are a small, oval or oblong fruit. They are grown chiefly for their oil, which can make up about half the flesh of the fruit.

oil. In the United States, the industry is based on preparing the fruit for eating. Oil is produced as a sideline.

Harvesting olives requires careful handling. Olives grown for their oil may be mechanically harvested. Olives grown for eating must be picked by hand. Workers place the fruit in small boxes and haul it to the processing plant. Fruit that must be shipped over long distances may be placed in barrels of brine.

Olives processed for eating are either green or black. One of three major processing methods may be used: (1) the Spanish, (2) the American, and (3) the Greek.

Most green olives are prepared by the Spanish process. In this process, unripe, yellowish-green olives are placed in lye solution. The lye removes most of the bitter taste of the oleuropein. The olives are washed and then fermented in brine. They are kept submerged continuously to prevent darkening, which can result from exposure to the air. The fermented olives may be pitted and stuffed with such fillings as almonds and pimentos. The fruit is then packed in fresh brine and pasteurized.

In the United States, most black olives are prepared by the American process. This process ripens immature, yellow-to-red olives artificially. The fruit is alternately submerged in lye and exposed to the air until no bitterness remains and the olives have turned brown to black. The fruit is then washed and pickled. After canning, the olives are sterilized at 240 °F (116 °C).

In the Greek process, ripe, purple-black olives undergo a slow fermentation in brine. During fermentation, the fruit's bitterness decreases until the brine masks it. This process traditionally does not use lye.

Production. Nations along the Mediterranean Sea grow most of the world's olives. Italy and Spain together produce more than half the world output. Greece is also a major olive-growing country. World olive production totals about 11 million tons (10 million metric tons) a year.

The United States olive crop comes entirely from California. Olive trees are cultivated in the southern and central parts of the state. The olive tree also grows along the Gulf of Mexico, but it does not bear fruit there.

George C. Martin

Scientific classification. Olives belong to the olive family, Oleaceae. Their scientific classification is *Olea europaea.*

See also **Forsythia; Olive oil; Spain** (picture: Olive orchards).

Olive oil is a fragrant, edible oil made from olives. It is used primarily as a salad dressing and as a cooking oil. It ranges in taste from sweet to bland and consists almost entirely of unsaturated fat (see **Fat**). Most olive oil has a light greenish-yellow color.

Olive oil is widely used in countries along the Mediterranean Sea. Italy is the world's leading producer of olive oil. Spain and Greece also make large quantities of olive oil. In the United States, it is produced only in California.

Olive oil is made by crushing and pressing ripe olives. Whole olive fruit consists of 10 to 40 percent oil, and the fruit pulp is 60 to 80 percent oil. Producers use hydraulic presses to squeeze the oil out of the fruit under low pressure. This technique, called *cold-pressing,* generates little heat, and so the oil retains its flavor, color, and nutritional value. Thus, olive oil, unlike most other vegetable oils, needs no further processing before being packaged. In addition, olive oil can be stored for months without refrigeration or danger of spoilage.

Cold-pressing commonly is carried out in several stages, with only some of the oil being extracted at each stage. The process remains basically the same throughout, but the quality of the oil declines with each pressing. In most cases, olives are cold-pressed at 40 °F (4 °C). Water is added during pressing to make the oil flow better. The oil is later separated from the water in a spinning machine called a *centrifuge,* or it is skimmed off the water's surface after settling there.

The first pressing gives the highest quality oil, which is usually called *virgin olive oil.* Virgin olive oil is more expensive than other vegetable oils, so it often is considered a gourmet item.

The lower-quality oils from later pressings are often blended in small amounts with such refined oils as soybean or cottonseed oil. Olive oil that comes from the final pressing is inedible. This oil, called *olive residue* or *olive foots,* is used in cosmetics, detergents, soap, medicines, and textiles. Daniel R. Sullivan

See also **Olive; Vegetable oil.**

Olives, Mount of. See Mount of Olives.

Olivier, *oh LIHV ee AY,* **Laurence** (1907-1989), became one of the leading English actors of the 1900's. Olivier was a versatile performer and was especially known for his acting in the plays of William Shakespeare. His film versions of Shakespeare's *Henry V* (1944), *Hamlet* (1948), and *Richard III* (1955) are considered classics. Olivier produced, directed, and starred in all three films. He won an Academy Award as best actor for his performance in *Hamlet.* Olivier was given a special Academy Award for his work as producer, director, and star of *Richard III.* In 1979, he received a special Academy Award for his lifetime achievement in motion pictures.

Olivier was born in Dorking. He made his professional stage debut in 1924. His first screen appearance was in 1930. Olivier gained international fame for his romantic roles in *Wuthering Heights* (1939) and *Rebecca* (1940). From 1963 until 1973, Olivier served as the first director of the National Theatre of Britain (now the Royal National Theatre).

Olivier was knighted in 1947. In 1970, he became Lord Olivier of Brighton, the first actor in English history to

Culver Pictures

be named a baron. His autobiography, *Confessions of an Actor,* was published in 1982. *On Acting* (1986) is a series of essays he wrote about his professional life.

Daniel J. Watermeier

Olivine, *AHL uh veen,* is any of a group of common rock-forming minerals that consist of silicon, oxygen, magnesium, and iron. Olivine occurs primarily in dark igneous rocks, usually as grainy masses or embedded crystals. It is generally one of the first minerals to crystallize from dark-colored *magma* (melted rock material).

Most types of olivine range in color from clear green to yellow-green, but iron-rich varieties may be brown. Olivine is relatively hard and cannot be scratched by a knife. The most common olivine is forsterite, which is rich in magnesium. Clear green olivine used as a gemstone is called *peridot* (see **Peridot**). David F. Hess

Olmec Indians, *OHL mehk,* developed what may have been the earliest civilization in the Americas. The Olmec civilization flourished between about 1200 and 400 B.C. The most important centers of Olmec culture were on the Mexican Gulf Coast, in what are now the southern Mexican states of Veracruz and Tabasco. By 400 B.C., the Olmec's sophisticated artistic style had spread over much of Middle America, from central Mexico to El Salvador. Some scholars have also recognized Olmec influences in the artwork and religious practices of many later Middle American cultures, including those of the Maya and the Aztec.

The Olmec lived near rivers in small thatched houses. They fished in the rivers and farmed lands made fertile by river flooding. The Olmec used a calendar and an early form of writing. At a number of sites, archaeologists have found large earthen mounds and uncovered ruins at what are believed to be Olmec religious centers. Artworks found at these sites include huge carved-stone heads that weigh up to 36,000 pounds (16,300 kilograms). The Olmec transported some of these gigantic stones more than 50 miles (80 kilometers) to the sites where the sculptures were discovered. Other objects found at the sites include mirrors of polished iron ore, carvings with both animal and human features, and groups of small stone figures arranged to represent religious ceremonies. William O. Autry

See also **Maya** (History); **Sculpture** (American Indian sculpture).

Olmsted, Frederick Law (1822-1903), was an American landscape architect, city planner, and writer on social issues. Olmsted's career was shaped by his idea of a civilized society. Through his landscape designs and writings, he tried to recast the form of America's cities and suburbs, and to promote the refinement and culture he thought the citizens of a republic could attain. He criticized the slaveholding South because he believed the region lacked the social and cultural institutions that would raise the level of civilization there.

In 1858, Olmsted and English architect Calvert Vaux submitted a plan for New York City's Central Park, America's first great urban park. Olmsted then supervised its construction and modified its design to give the park its most distinctive features. These include the separation of all forms of traffic and the sweeping natural scenery that would provide New Yorkers with an alternative to the sights and sounds of the city. After 1872, Olmsted and various partners designed Belle Isle Park in Detroit, Mount Royal Park in Montreal, and Roger Williams Park in Providence, Rhode Island. Olmsted planned park systems for Seattle; Boston; Atlanta, Georgia; New York City; and Louisville, Kentucky.

In addition, Olmsted planned suburban developments, colleges, and the grounds for many institutions and public buildings. His most notable designs include the grounds of the U.S. Capitol in Washington, D.C. (1874), the layout for the World's Columbian Exposition in Chicago (1893), and the New York State Reservation at Niagara (1879). Olmsted also designed such communities as Riverside, Illinois; and Parkside, in Buffalo, New York.

Olmsted was born in Hartford, Connecticut. His son, Frederick Law Olmsted, Jr., was also a well-known landscape architect and city planner. David Schuyler

Olson, Charles (1910-1970), was one of the most influential American poets of his time. In 1948, Olson began teaching at Black Mountain College, an experimental school in Black Mountain, North Carolina. He served as the school's *rector* (head) from 1951 to 1956. At the college, Olson taught Robert Creeley, Robert Duncan, and other young writers who became leading poets.

Charles John Olson was born in Worcester, Massachusetts. His chief work was a long *cycle* (series of poems) called *The Maximus Poems.* Publication of this complex work began in 1953 and ended in 1975 after his death. In it, Olson used Gloucester, Massachusetts, symbolically to praise what he admired in human life and to attack the greed and commercialism he saw in American culture.

Olson first gained recognition with *Call Me Ishmael* (1947), a critical study of the American author Herman Melville. Olson's major poems and critical writings appear in *Selected Writings* (1966). This collection includes Olson's well-known essay "Projective Verse" (1950), in which he discussed his extremely complicated style of poetry. Elmer W. Borklund

Olympia, *oh LIHM pee uh,* is a valley about 11 miles (18 kilometers) from Pírgos, Greece. In ancient times, religion, politics, and athletics centered at Olympia. The Olympic Games, held there every four years, were so important in Greek life that they were used as the basis for the calendar. All the buildings in Olympia were for worship or for games. The religious buildings were clustered in the *Altis* (sacred grove), which lies where the Cladeus River flows into the Alfios River. They included the temples of Zeus and Hera, the Pelopion, the Philippeion, and the great altars.

The athletic buildings lay just outside the Altis. They included a gymnasium; the palaestra, a wrestling and boxing school; the stadium; and the hippodrome, where chariot and horse races were held.

The Olympic Games were banned in A.D. 393, and a fort was built in the Altis. Later, earthquakes and floods covered Olympia under 20 feet (6 meters) of earth.

In 1829, a French expedition began excavations at the temple of Zeus. The German government continued this work. Between 1875 and 1879 the entire Altis and many of the surrounding buildings were uncovered. Fragments of sculpture, coins, terra cottas, and bronzes have been found. The major discoveries were two statues, the *Victory of Paeonius* (423 B.C.) and the *Hermes of Praxiteles.* The originals of all discoveries remained in

possession of Greece. The Germans reserved the right to take casts from sculptures, coins, or other discoveries. A museum with Olympian relics is at the modern town of Olympia at the edge of the ruins. The modern town provides hotels and other services to the many tourists who visit the ruins. John J. Baxevanis

See also **Olympic Games**.

Olympia, *oh LIHM pee uh* (pop. 42,514; met. area pop. 207,355), is the capital of the state of Washington, and the gateway to southwestern Washington and the Olympic Peninsula. An important commercial port, the city lies on the southern inlets of Puget Sound (see **Washington** [political map]). Oceangoing ships use Olympia's harbor to export logs, lumber, and other goods. Beds of the Olympia oyster lie in shallow waters near Olympia. Major industries include brewing, food processing, and the manufacture of metal and lumber products. Many Olympians work for the state government. The state capitol, called the Legislative Building, sits on a forested bluff. Its 287-foot (87-meter) dome towers over the area.

Fort Lewis, one of the nation's largest U.S. Army posts, lies between Olympia and Tacoma. Schools in the area include Evergreen State and St. Martin's colleges.

Homesteaders began to settle in the area in the 1840's. Edmund Sylvester pioneered in the development of the townsite. Olympia became the territorial capital when the Washington Territory was created in 1853. The city was incorporated in 1859. Olympia has been the state capital since Washington became a state in 1889. In February 2001, a powerful earthquake struck western Washington. Olympia suffered much property damage.

Olympia is the seat of Thurston County. A city manager heads the local government. Mindy Chambers

Olympiad, *oh LIHM pee ad.* In the Greek system of telling time, an Olympiad was the period of four years that elapsed between two successive celebrations of the Olympian, or Olympic, Games. This way of figuring time became common about 300 B.C. All events were dated from 776 B.C., the start of the first known Olympiad.

The beginning of the year of the Olympiad was determined by the first full moon after the summer solstice, the longest day of the year. This full moon fell about the first of July. Therefore, only the last six months of the first year of the 195th Olympiad corresponded to the first year of Our Lord. This method of counting time ceased about A.D. 440, after the 304th Olympiad. The Olympiads were used as measures of time by later Greek historians and other writers to refer to preceding centuries, but they were never in everyday use, as were months and years. James Jespersen

Olympians. See **Mythology** (Greek mythology).

Olympias, *oh LIHM pih uhs* (375?-316 B.C.), was the wife of Philip II of Macedonia and the mother of Alexander the Great. A proud and emotional woman, Olympias influenced Alexander greatly. She told Alexander that his real father was the god Zeus-Ammon, not Philip. Olympias feared that Philip might choose another heir. Many people believe she had Philip killed to ensure that Alexander would become king. After Alexander's death in 323 B.C., Olympias tried to keep the empire for her grandson, Alexander IV. She failed, and in 316 B.C. was captured by Cassander, a Macedonian prince. Olympias was eventually killed. See also **Alexander the Great** (His youth); **Philip II**. Judith P. Hallett

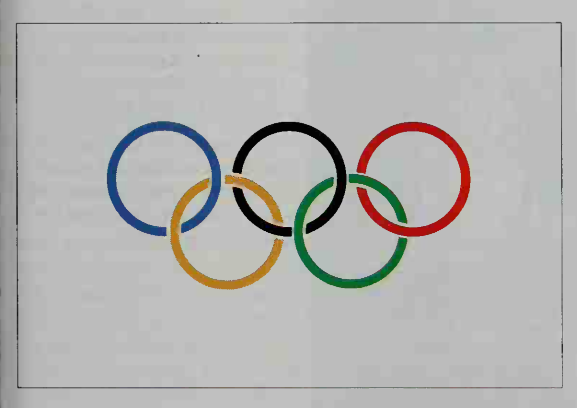
Olympic Games

Olympic Games are the most important international athletic competition in the world. The Olympics bring together thousands of the world's finest athletes to compete against one another in a variety of individual and team sports. Millions of people have attended the games, and more than 1 billion people throughout the world watch the Olympics on television.

The Olympic Games originated in ancient Greece and were held from 776 B.C. to A.D. 393. The modern games began in 1896. The organizers revived the games to encourage world peace and friendship and to promote healthy sporting competition for the youth of the world.

The Olympic Games consist of the Summer Games and the Winter Games. From 1896 to 1992, the Olympics were held every four years, except in 1916 during World War I, and in 1940 and 1944 during World War II. The Winter Games, which were established in 1924, took place the same year as the Summer Games. Beginning in 1994, the Winter and Summer Games were divided and scheduled on four-year cycles two years apart. For the years and locations of the games, see the table *Sites of the Olympic Games* in this article.

Olympic ceremonies and symbols



Colorful ceremonies combine with thrilling athletic competition to create the special feeling of excitement in the Olympics. The opening ceremony is particularly impressive. The Olympic athletes of Greece march into the stadium first, in honor of the original games held in ancient Greece. The athletes of the other countries fol-

Paul J. Sutton, Duomo

The opening ceremonies of the Olympic Games feature the entry of the athletes into the stadium. Athletes from Greece enter first, followed by teams from the other countries.

The Olympic symbol consists of five interlocking rings that represent Africa, Asia, Australia, Europe, and the Americas.

low in alphabetical order by country according to the spelling in the language of the host country. The athletes of the host country enter last. The president or other head of state of the host country opens the games. The Olympic flag is raised, trumpets play, and cannons boom in salute.

The most dramatic moment of the opening ceremony is the lighting of the Olympic flame. The flame symbolizes the light of spirit, knowledge, and life; and it is a messenger of peace. The fire is ignited in Olympia, Greece, by using a mirror to concentrate the rays of the sun. Runners transport the flame in a torch relay from Greece to the site of the games.

Most runners carry the flame on foot. However, many other kinds of transportation, including airplanes, horses, and skis, have also been used. The final runner carries the torch into the stadium, circles the track, and lights a huge *caldron* (kettle). The flame burns throughout the games and then is extinguished during the closing ceremony.

The Olympic symbol, created in 1913, consists of five interlocking rings that represent the continents of Africa, Asia, Australia, Europe, and the Americas. The colors of the rings, from left to right, are blue, yellow, black, green, and red. The flag of every nation competing in the games has at least one of these colors. Under the rings is the Olympic motto, the Latin words *Citius, Altius, Fortius.* The words are translated as *Swifter, Higher, Stronger.*

The International Olympic Committee

The International Olympic Committee (IOC) is the governing body of the Olympic Games. The IOC has headquarters in Lausanne, Switzerland. The committee approves the sports and events to be included in the games. The IOC also selects the host cities for the Summer Games and Winter Games, seven years in advance. The cities bidding for the games must prove they can provide athletic facilities for the games and housing for the athletes, coaches, officials, and visiting spectators.

Manny Millan, *Sports Illustrated*

The Olympic flame is lit during the opening ceremonies. The fire is ignited in Olympia, Greece, and transported by relay to the site of the games. The flame symbolizes the light of spirit, knowledge, and life, and it is a herald of peace.

David Black

The medal ceremony takes place after the finals of each event. The top three finishers receive a medal and a diploma. They stand at attention on a platform while the flags of their countries are raised and a band plays the national anthem of the country of the gold medal winner.

Host cities provide a special housing compound called the Olympic Village for the athletes and coaches. The prospective hosts must also convince the IOC that they can furnish adequate transportation, food service, and cultural activities. Host cities are chosen by a majority vote of the IOC.

Originally, members of the IOC were elected for life. However, according to a rule change in 1995, all members must retire before they reach the age of 81. The members of the IOC are not allowed to accept instructions on voting from any government or other group or individual. New members of the IOC are elected by current members. There are no rules setting the size of the IOC or what countries should be represented.

Olympic competition

Every country or territory competing in the Olympic Games is represented by a national Olympic committee. In the mid-1990's, about 195 nations and territories had such groups. Each committee is responsible for selecting its national team, providing uniforms and equipment, and furnishing transportation to the Olympic site.

AP/Wide World

The closing ceremonies come after the end of the athletic competition. The ceremonies are marked by spectacle and conclude with the extinguishing of the Olympic flame, which had burned throughout the competition.

Most countries use government funds to pay their Olympic expenses. The IOC also provides financial aid. The United States is the only large nation whose government does not give its team financial support. The U.S. team is largely financed by contributions from private corporations and individuals.

Selection of the athletes. In many countries, athletes qualify for the Olympics by winning or finishing high in competitions called *selection trials.* In most cases, athletes are invited to the trials based on their performance in national and international competitions.

An athlete representing a country must be a citizen of that country. For many years, only amateur athletes competed in the games. This gave an advantage to wealthy athletes who could devote all their time to training without worrying about earning money. Professional athletes are now eligible to compete in most Olympic sports. Exceptions include baseball and boxing.

Entries. In most Olympic sports, a nation may enter as many as three competitors in each event as long as the athletes meet a minimum standard set by the international governing body of that sport. Team sports are limited to 8 to 16 teams per sport. National teams must win or place high in qualifying tournaments to make the final competition. The host country is allowed to enter a team in every team event.

Medals. The top three finishers in each event receive a medal and a diploma. The next five finishers get only a diploma. Each first-place winner receives a gold medal, which is actually made of silver and coated with gold. The second-place medal is made of silver, and the third-place medal is bronze. The design for the medal changes for each Olympics. All members of a winning relay team get a medal, including those who participated only in qualifying rounds. In team sports, all the members of a winning team who have played in at least one of the games during the competition receive a medal.

The top three finishers receive their medals in a ceremony after the event. The medal winners stand at attention on a platform, with the gold medalist in the middle. The silver medalist stands on the gold medalist's right and the bronze medalist on the left. The flags of their countries are raised, and a band plays the national anthem of the country of the gold medal winner.

Olympic competition is intended to test the skill of individuals and teams, not nations. Therefore, the IOC does not keep an official score among the nations. No country "wins" the Olympics. However, unofficial medal totals are compiled for the press and the public.

The Summer Games

The Summer Games are held during the summer season of the host city, usually between July and October, and last 16 days. Athletes compete in more than 270 separate events during the Summer Games. A sport must be played in at least 75 countries on four continents before it can be considered for men's competition. To be eligible for women's competition, a sport must be played in 40 countries on three continents.

The Summer Games have grown enormously. In the first modern games in 1896, about 311 male athletes representing 13 nations competed. Today, more than 10,000 male and female athletes representing over 190 nations participate.

The Winter Games

The Winter Games are usually held in February and last 16 days. A sport must be played in at least 25 countries on three continents to be considered. The Winter Olympics include over 60 events. The games attract approximately 2,000 athletes from about 60 countries.

The ancient games

Athletics played an important role in the religious festivals of ancient Greece. Historians believe the ancient Greeks first organized athletic games as part of funeral ceremonies for important people. This practice probably existed by the 1200's B.C. Later, games became part of religious festivals honoring the gods. Many Greek cities held festivals every two or four years.

Over time, four great religious festivals developed that brought together people from throughout the Greek world. These festivals were the Isthmian, Nemean, Pythian, and Olympic games. The Olympic Games, which ranked as the most important, honored Zeus, the king of the gods.

The first recorded Olympic contest took place in 776 B.C. at Olympia in western Greece. The first winner was Koroibos (also spelled Coroebus), a cook from Elis. The Olympic Games were held every four years. They were so important to the ancient Greeks that time was measured in *Olympiads,* the four-year intervals between games. The only event in the first 13 games was the *stadion,* a running race of 192 meters (210 yards). Through the years, longer running races were added.

Other types of competition became part of the ancient Olympics. In 708 B.C., wrestling and the pentathlon were added. The pentathlon was a combination of jumping, running, the discus throw, the javelin throw, and wrestling. Boxing joined the program in 688 B.C., and the four-horse chariot race was added in 680 B.C. Horse racing was included in 648 B.C., as was the *pancratium* (also spelled *pankration*), a combination of boxing, wrestling, and kicking. Some unusual events were included in the Olympics, such as a race in armor, a chariot race called the *apene* in which two mules pulled the chariot, and a competition for trumpeters.

The ancient Olympics produced several famous champions. Milo of Kroton won the wrestling competition five times between 532 and 516 B.C., and Leonidas of Rhodes won three running races in each of four Olympics from 164 to 152 B.C.

The Romans conquered Greece during the 140's B.C., and the games soon lost their religious meaning. In A.D. 393, Emperor Theodosius I banned the games.

The modern games

The modern games begin. In 1875, a group of German archaeologists began to excavate the ruins of the stadium and temples of Olympia, which had been destroyed by an earthquake and buried by a landslide and floods. Their discoveries inspired Baron Pierre de Coubertin, a French educator, to organize a modern international Olympics. He first proposed the idea publicly in 1892. In 1894, the first IOC was formed.

The first modern Olympic Games were held in Athens, Greece, in 1896. The athletes competed in nine sports: (1) cycling, (2) fencing, (3) gymnastics, (4) lawn tennis, (5) shooting, (6) swimming, (7) track and field, (8) weightlifting, and (9) wrestling. James B. Connolly of the United States became the first modern Olympic champion, winning the triple jump (then known as the *hop, step, and jump*).

The games of 1900 and 1904 attracted little attention. The 1900 Olympics were held as part of the Universal

Black-figure painting (about 530 B.C.) on a Greek vase; The Metropolitan Museum of Art, New York City, Rogers Fund, 19

The ancient Olympic Games were held every four years in Olympia in western Greece. The first recorded games took place in 776 B.C. For the first 13 competitions, the only event was a running race for male athletes, *above,* of 192 meters (210 yards). Other events were added over the years.

Exposition, a world's fair in Paris. Competition was spread out over five months. Attendance was poor, and some athletes did not even realize they had participated in the Olympics. The 1900 Olympics included the first competitions involving women, in lawn tennis and golf. The first women gold medalists were British tennis player Charlotte Cooper and American golfer Margaret Abbott. Poor attendance and other problems also plagued the 1904 Olympics, held as part of the Louisiana Purchase Exposition in St. Louis, Missouri.

In the early years of the Olympics, competitions were held in several sports that were later dropped. They included polo, croquet, tug of war, live pigeon shooting, the high jump on horseback, and a swimming obstacle race.

The Olympic movement might have died except for the *Intercalated,* or *Interim,* Games held in Athens in 1906. The IOC did not consider these games official. However, they were popular and held the movement together until the next official games in London in 1908. The most dramatic moment of the 1908 games came in the marathon. Dorando Pietri of Italy entered the stadium in first place but collapsed before reaching the finish line. Officials dragged Pietri across the finish line and declared him the winner, but he was later disqualified because he did not finish under his own power.

The 1912 Olympics in Stockholm, Sweden, were the first well-organized Olympic Games. The hero of Stockholm was Jim Thorpe, an American Indian who easily won the 10-event decathlon and the 5-event pentathlon. Thorpe's medals were taken away after it was discovered that he had played baseball for a small salary before the games, making him a professional athlete and therefore ineligible for the Olympics. In 1982, the IOC voted to return the medals to Thorpe's family and put his name back in the record books as an Olympic champion.

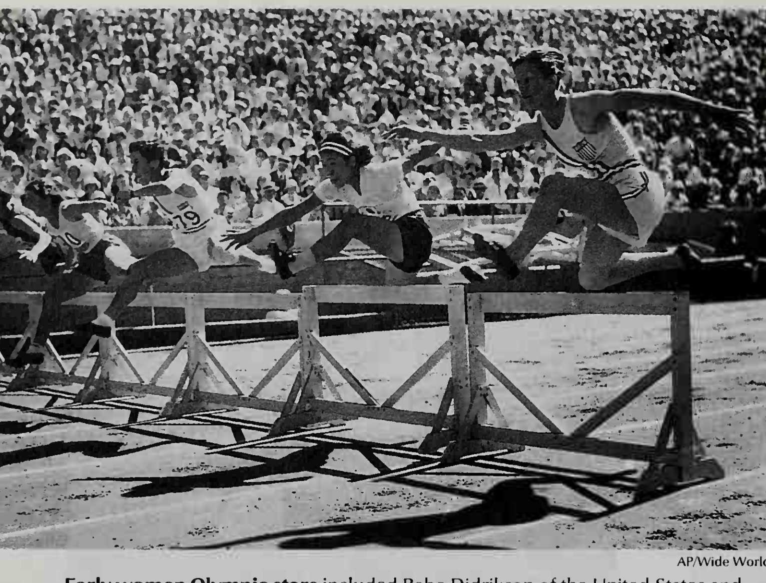
Hulton Deutsch from All Sport

Jim Thorpe of the United States won the decathlon and pentathlon at the 1912 Summer Games. His medals were taken away after he was declared ineligible, but they were restored in 1982.

Between the wars. The 1916 games were canceled because of World War I (1914-1918). The 1920 Olympics in Antwerp, Belgium, marked the first appearance of the great Finnish distance runner Paavo Nurmi. He competed in all three Olympics of the 1920's, winning nine gold medals.

Figure skating was included in the 1908 games, and both figure skating and ice hockey were part of the 1920 games. The first separate Winter Games took place in Chamonix, France, in 1924, with 281 men and 13 women representing 16 countries.

The 1924 Summer Games were held in Paris. One of the stars was American swimmer Johnny Weissmuller, who later became famous portraying Tarzan in motion pictures. Other famous athletes included British sprinters Harold Abrahams and Eric Liddell, later portrayed in the film *Chariots of Fire* (1981).



The 1928 Summer Games, held in Amsterdam, the Netherlands, were the first in which women competed in track and field. In the Winter Games in St. Moritz, Switzerland, Sonja Henie of Norway won her first gold medal in women's figure skating. She repeated as champion in the 1932 and 1936 Winter Games before becoming a star of Hollywood musicals.

The 1932 Summer Games were held in Los Angeles. These games introduced automatic timing for races and the photo-finish camera. The first Olympic Village was also erected. The games produced the first U.S. female Olympic star, Babe Didrikson (later Babe Didrikson Zaharias). She qualified for five track and field events but was allowed to enter only three. She won the javelin throw and the hurdles race and finished second in the high jump.

In 1931, the IOC chose Berlin, Germany, as the site for the 1936 Summer Games and Garmisch-Partenkirchen, Germany, for the Winter Games. Two years later, Adolf Hitler and his Nazi Party rose to power in Germany. As Hitler's policies became known, there were pleas to move the Summer Games, but the IOC refused.

The Berlin games were the first to be preceded by a torch relay of the Olympic flame from Greece, and they were the first games to be shown on television. But the 1936 Summer Olympics are best remembered for Hitler's failed attempt to use them to prove his theory of racial superiority. The Nazis glorified the Germans and other northern European peoples, while claiming that Jews, blacks, and other groups were inferior. But the most successful athlete in the Summer Games was Jesse Owens, an African American who won four gold medals in track and field. The German spectators, ignoring Hitler's speeches against black people, treated Owens as their favorite hero of the games.

The postwar games. The Olympics scheduled for 1940 and 1944 were canceled because of World War II (1939-1945). The first postwar Summer Games were held in London in 1948 and the Winter Games again in St. Moritz. The most popular athlete in the Summer Games was Fanny Blankers-Koen of the Netherlands, a home-

AP/Wide World

All Sport

Early women Olympic stars included Babe Didrikson of the United States and Sonja Henie of Norway. Didrikson, *running far right,* won the hurdles in the 1932 Summer Games. She also won the javelin throw and finished second in the high jump. Henie, *shown here,* won the gold medal in figure skating in 1928, 1932, and 1936, the only woman to win the event three times.

maker who won four gold medals in track and field. A star of the Winter Games was Dick Button of the United States, who won the gold medal in figure skating, an achievement he repeated in the 1952 games. Barbara Ann Scott of Canada won the women's figure-skating title, becoming the first Canadian figure skater to win an Olympic gold medal.

Athletes from the Soviet Union made their first Olympic appearance in the 1952 Summer Games in Helsinki, Finland. By the 1956 games, Soviet athletes were winning more medals than the athletes of any other country. In Helsinki, Emil Zátopek of Czechoslovakia became the only runner to win the 5,000 meters, 10,000 meters, and marathon races in the same Olympics.

The 1956 Summer Games were held in Melbourne, Australia, the first to be held in the Southern Hemisphere. Because of Australian quarantine laws concerning horses, the equestrian events were staged separately in Stockholm. In the weeks preceding the Melbourne games, Israel invaded Egypt and Soviet troops invaded Hungary. These actions led to the first boycotts of the modern Olympics. Egypt, Iraq, and Lebanon withdrew to protest the Israeli take-over of the Suez Canal. The Netherlands and Spain boycotted to protest the Soviet invasion.

The 1960 Winter Games at Squaw Valley in California and the Summer Games in Rome were the first to be televised to the United States. The track and field stars of the Summer Games included American sprinter Wilma Rudolph and marathon winner Abebe Bikila of Ethiopia, the first black African to win a gold medal. American boxer Cassius Clay won the light heavyweight gold medal. He later gained international fame as professional boxer Muhammad Ali.

In 1964, the Summer Games were held in Tokyo, the first Asian city to serve as host. Ukrainian gymnast Larisa Latynina won six medals. In her career, she won a record 18 Olympic medals. The Tokyo games were the last Summer Games for more than 20 years to be free of major controversy.

The 1968 games. The 1968 Summer Games were held in Mexico City during a period of political turmoil throughout the world. The most controversial episode took place during the medal ceremony for the men's 200-meter dash. The gold and bronze medals were won by African American sprinters Tommie Smith and John Carlos. To protest racism in the United States, both athletes bowed their heads and raised clenched fists during the playing of the U.S. national anthem. At the insistence of the IOC, the U.S. Olympic Committee suspended both men from the Olympic team and ordered them to leave the Olympic Village.

Mexico City's high altitude was disastrous for athletes in long-distance races and other endurance events, but it contributed to world records in many other contests. The most famous record was 29 feet 2 $\frac{1}{2}$ inches (8.90 meters) in the long jump, set by Bob Beamon of the United States. The jump became a new world record that lasted for 23 years.

The 1968 Winter Games in Grenoble, France, produced one of the great Olympic heroes of the 1960's. French skier Jean-Claude Killy won three gold medals and became an international celebrity.

Terrorism in Munich. The 1972 Summer Games were held in Munich, in what was then West Germany. The Munich Olympics are remembered for the events of September 5. Eight Palestinian terrorists broke into the Olympic Village and entered the dormitory where the Israeli team was staying. They killed two Israelis and took nine hostages. They demanded that Israeli authorities release more than 200 Arab prisoners being held in Israel. During a battle with West German sharpshoot-

ers, all the Israeli hostages were killed, along with five terrorists and one policeman.

The highlight of the competition was swimmer Mark Spitz of the United States, who won seven gold medals. The Soviet Union also won a controversial victory over the U.S. men's basketball team in the championship game. The Americans led by 1 point when the buzzer sounded to end the game. But the officials twice ordered the game to continue, first for 1 second and then for 3 seconds more, enabling the Soviet team to score the winning basket.

Boycotts. The 1976 Summer Games, held in Montreal, Canada, were hit by a boycott led by Tanzania. More than 20 African nations and 2 other countries refused to compete. The boycotters demanded that New Zealand be banned from competition because a New Zealand rugby team had toured South Africa. At that time, South Africa had a white-controlled government that enforced a policy of rigid racial segregation called *apartheid.* South Africa was barred from the Olympics because of its racial policies, but the IOC said it had little control over the travel of rugby teams because rugby was not an Olympic sport.

In spite of the absence of hundreds of top athletes, the 1976 games were filled with outstanding performances. A 14-year old gymnast from Romania named Nadia Comaneci caused a sensation by earning the first perfect score of 10 ever awarded in the Olympics. She eventually earned seven scores of 10 and won three gold medals.

The 1980 Summer Games in Moscow were disrupted by another boycott, this one led by U.S. President Jimmy Carter. The boycott protested the Soviet Union's 1979 invasion of Afghanistan. Carter urged other nations to join the boycott, and about 55 nations stayed away as part of the protest.

The 1980 Winter Games in Lake Placid, New York, were among the most exciting in history. Eric Heiden

Wide World

Jesse Owens of the United States was the hero of the 1936 Summer Games. Owens won four gold medals in track and field.

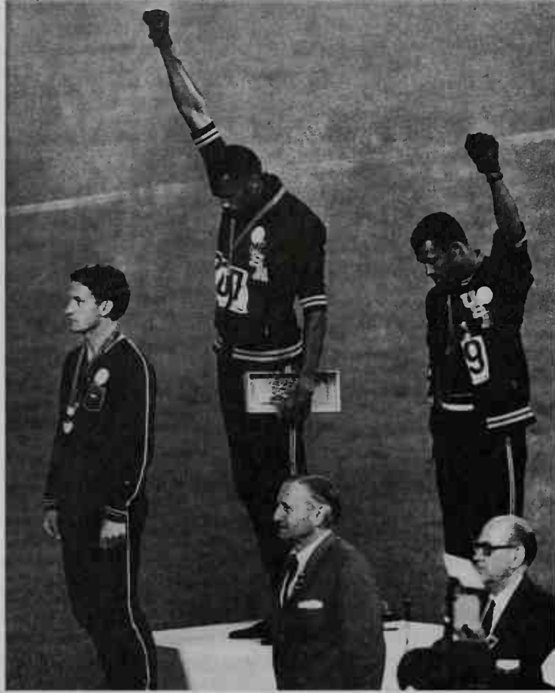
won all five speed-skating races, setting an Olympic or world record in each race. He became the first athlete to win five individual gold medals in one Olympics. Mark Spitz had won three of his seven gold medals as a member of a winning relay team.

Also at the 1980 Winter Games, the United States ice hockey team won an unexpected gold medal. The American team upset the Soviet Union team in an emotional semifinal match and then defeated Finland in the finals.

The games returned to Los Angeles in 1984. With the games being held in the United States, the Soviet Union launched a revenge boycott. Only 13 countries joined the boycott, but they included such sports powers as Bulgaria, East Germany, Cuba, and Hungary. Among the sports that lost most of their medal favorites were weightlifting, wrestling, gymnastics, women's swimming, and women's track and field. However, China competed in the Olympics for the first time in more than 30 years. China was led by the popular gymnast Li Ning, who won six medals. United States track and field star Carl Lewis matched Jesse Owens's 1936 feat of winning four gold medals.

Charges of steroid use. The 1988 Summer Games were held in Seoul, South Korea, and were boycotted by North Korea and Cuba. Instead of political controversy, disputes over the use of drugs called *anabolic steroids* marked the 1988 games. Anabolic steroids are artificial forms of male hormones used to increase strength and weight. Their use is banned in Olympic competition. Since 1968, the IOC has tested athletes for steroids and other performance-enchancing drugs.

In the 1988 Olympics, Ben Johnson of Canada defeated Carl Lewis in the 100-meter dash and set a world record. Three days later, the IOC announced that Johnson had tested positive for steroids and was disqualified. Lewis was awarded the gold medal, thus becoming the first man to win the 100-meter dash twice. He also won the long jump for the second time. Other notable performers were swimmers Matt Biondi of the United States, who won five gold medals, and Kristin Otto of East Germany, who won six.



In the 1988 Winter Games in Calgary, Canada, Katarina Witt of East Germany won the women's figure-skating title. Witt also had won the event in 1984. She was the first woman to repeat as champion since Sonja Henie.

The recent games. The 1992 Summer Games in Barcelona, Spain, reflected the breakup of the Soviet Union and the collapse of Communist governments in Eastern Europe. Germany entered a unified team representing the former countries of East and West Germany. The Baltic states of Estonia, Latvia, and Lithuania, previously part of the Soviet Union, competed as separate nations. Russia and other former Soviet republics competed as the Unified Team. However, when athletes from the Unified Team won a medal, they were honored by the raising of the flag of their own republic and by the playing of their own national anthem. South Africa, which had ended apartheid, rejoined the Olympics and competed for the first time since 1960.

The 1992 Olympics also marked the first time that professional basketball players were eligible for the competition. This rule change led to the creation of a U.S. "Dream Team" that included Magic Johnson, Larry Bird,

Michael Jordan, Charles Barkley, and other stars of the National Basketball Association. The American team easily won the gold medal.

Speed-skater Bonnie Blair was a star of the Winter Games of 1988, 1992, and 1994. She won five gold medals and a bronze medal in the three games.

AP/Wide World

Controversy erupted in 1968 when American sprinters Tommie Smith, *center,* and John Carlos raised clenched fists at a medal ceremony to protest racism in the United States.

The 1996 Summer Games were held in Atlanta, Georgia. Stars included Russian gymnast Alexei Nemov, who won six medals; South African swimmer Penny Heyns, who set two Olympic records; and Michael Johnson of the United States, the first male track athlete to win the 200-meter and 400-meter races in the same Olympics.

The 2000 Summer Games in Sydney, Australia, were the largest in Olympic history, with athletes competing for medals in 300 events. Drug problems continued to cast a cloud over the games. Several athletes were disqualified for taking illegal drugs. Some forfeited medals after failing drug tests. Stars of the games included Marion Jones of the United States in track and field, Australian swimmer Ian Thorpe, Chinese diver Fu Mingxia, and cyclist Leontien Ziljaard of the Netherlands.

A controversy arose in the 2002 Winter Games over the judging of the figure skating pairs competition. Judges first awarded the gold medal to Elena Berezhnaya and Anton Sikharulidze of Russia and the silver medal to Jamie Sale and David Pelletier of Canada. After a protest and investigation, the Canadians were awarded a gold medal along with the Russians.

Great moments in Olympic competition occurred in the 1976 and 1980 games. In the 1976 Summer Games, Nadia Comaneci of Romania, *shown here,* became the first gymnast in Olympic history to score a perfect 10. In the 1980 Winter Games, the United States ice hockey team upset the Soviet team in the semifinals, *shown here,* and then defeated Finland to win the gold medal.

Andrew Bernstein, *Sports Illustrated*

The "Dream Team" was the name given to the American men's basketball team that won the gold medal at the 1992 Summer Games. The stars of the team came from the National Basketball Association. The 1992 Olympics marked the first time professional players could participate. American professional teams also won in 1996 and 2000.

Olympic Mountains, *oh LIHM pihk,* are part of the Pacific Coast Ranges. The Olympics rise in northern Washington, south of Juan de Fuca Strait. These mountains occupy an area of about 3,500 square miles (9,060 square kilometers), most of which lies in Olympic National Park.

Mount Olympus (7,965 feet, or 2,428 meters) is the highest peak. There are over 100 small glaciers in the mountains. Forests of spruce, fir, cedar, and hemlock cover the lower slopes. The southwestern slopes receive over 140 inches (356 centimeters) of rain a year, one of the highest averages in the United States.

Jois C. Child

Olympic National Park, *oh LIHM pihk,* lies in the Olympic Peninsula of Washington, not far from Seattle and Tacoma. The jagged peaks of the Olympic Range cover much of the national park. For the area of Olympic National Park, see **National Park System** (table: National parks). The park has campgrounds and winter sports activities for tourists. Olympic National Park headquarters are at Port Angeles, Washington, a resort city on the Strait of Juan de Fuca.

Of special interest are the rain forests consisting mainly of Sitka spruce, western hemlock, western redcedar, and Douglas-fir. These rain forests, resulting from good soil and exceptionally heavy rainfall, are almost tropical in luxuriance, with an undergrowth of vine maple, bigleaf maple, ferns, and other junglelike growth. Mosses drape the branches and tree trunks. The park is the home of the world's largest herd of Roosevelt elk, estimated at 5,000 animals. Other wildlife species include black bear, cougar, and black-tailed deer.

This wilderness of glacier-clad peaks, flower-strewn alpine meadows, turbulent streams and jewellike lakes, and deep valleys supporting a rich forest growth is often described as America's "last frontier." Highways penetrate only its outer fringes, but the park has several hundred miles of hiking and horseback riding trails. Nearly 1,000 varieties of flowers grow in the park's meadows and on its mountain slopes. Some varieties, such as the *Piper bellflower,* grow nowhere else.

Part of this region was set aside as Mount Olympus National Monument by President Theodore Roosevelt in 1909. In 1938, President Franklin D. Roosevelt signed the act establishing Olympic National Park. The park was formally dedicated in 1946. The Queets Corridor and Olympic Ocean Strip were added to the park by presidential proclamation in 1953.

Omaha, *OH muh HAW* or *OH muh HAH* (pop. 390,007; met. area pop. 716,998), is the largest city in Nebraska. It ranks as one of the world's leading food processing centers. The city also serves as the trading center for eastern Nebraska and western Iowa. For the location of Omaha, see **Nebraska** (political map).

Omaha took its name from the Omaha Indians. In 1854, this tribe gave most of its hunting grounds in the eastern Nebraska area to the United States government. That same year, the Council Bluffs and Nebraska Ferry Company, a land development firm, founded the town of Omaha City. The name of the town was later shortened to Omaha. The company chose the site for settlement because of its location on a bluff at a ferry crossing at the start of the Mormon Trail.

The city covers 102 square miles (264 square kilometers) on the west bank of the Missouri River. The city of Council Bluffs, Iowa, lies across the river and makes up part of the Omaha metropolitan area. This area covers 2,476 square miles (6,413 square kilometers) and consists of Cass, Douglas, Sarpy, and Washington counties in Nebraska and Pottawattamie County in Iowa.

Omaha's main business district lies near the Missouri River. In the heart of the downtown area stands the city's tallest building, the 45-story First National Center.

Whites make up about 78 percent of Omaha's population. About 13 percent of the people are African Americans. Hispanics of any race make up about 8 percent. The city also has a small number of Asians and American Indians.

Economy. Omaha has about 550 manufacturing plants. Food processing ranks as the city's most important industry. Omaha is one of the chief frozen food producers in the United States.

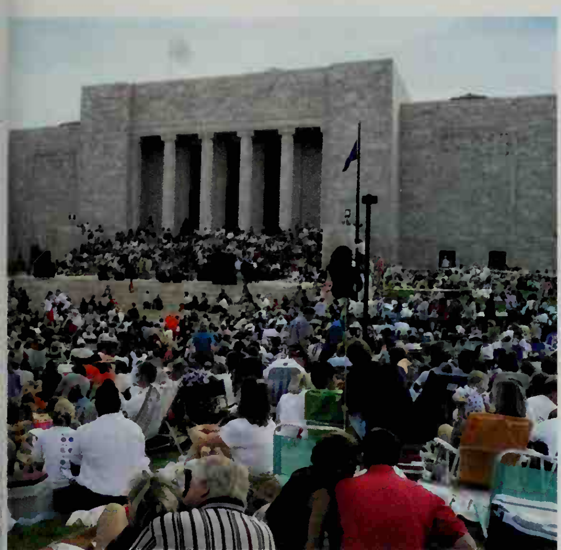
Other major Omaha industries include machinery manufacturing, metalworking, printing, publishing, and the manufacture of telephone and electric equipment. The city is a national center for telemarketing companies, which promote and sell products by telephone. Omaha is also an insurance center. About 35 insurance firms have their home offices in the city, including Mutual of Omaha, one of the largest insurance companies in the United States.

Railroads provide freight service to Omaha, and passenger trains also serve the city. Airlines use Eppley Airfield. Bus lines and trucking firms also operate in Omaha. Barge lines help make the city an important Missouri River port. Omaha has one daily newspaper, the *Omaha World-Herald.*

Education. Omaha is the home of the Nebraska School for the Deaf. Girls and Boys Town, a famous community for homeless and underprivileged children, is just west of Omaha (see **Girls and Boys Town**).

Colleges and universities include the University of Nebraska at Omaha, Creighton University, the University of Nebraska Medical Center, the College of St. Mary, and Grace College of Bible. The campuses of the Metropolitan Technical Community College are also in Omaha.

Cultural life and recreation. The Joslyn Art Museum features works from ancient to modern times, with a special emphasis on European and American art of the 1800's and 1900's. The museum is noted for its collection of art of the American West. Other museums include the Omaha Children's Museum and the Durham Western Heritage Museum, a history museum in a restored railroad station. The city has a symphony orchestra. The Omaha Community Playhouse, which first opened in 1925, presents plays in two theaters.



Omaha has more than 120 parks, which cover a total of about 5,000 acres (2,000 hectares). The Henry Doorly Zoo, in the southeastern part of the city, attracts many visitors. The zoo's Lied Jungle is an indoor re-creation of rain forests of Asia, Africa, and South America. Lauritzen Gardens, Omaha's Botanical Center, is just north of the zoo. Fontenelle Forest, the largest unbroken tract of forestland in Nebraska, lies south of Omaha.

Every June, top college baseball teams come to Omaha to compete in the National Collegiate Athletic Association College World Series. The Knights of Ak-Sar-Ben, a civic organization with more than 25,000 members, sponsors a rodeo and livestock show every September. This organization, whose name is *Nebraska* spelled backwards, was founded in 1895.

Government. Omaha has a mayor-council form of government. The voters elect the mayor and the seven council members to four-year terms. Omaha gets most of its income from a property tax and a city sales tax.

History. Many Indian tribes, including the Omaha and the Oto, once hunted buffalo in what is now the Omaha area. The famous expedition headed by Meriwether Lewis and William Clark passed through the area in 1804 on its way to the West.

In 1854, a treaty between the United States government and the Omaha Indians opened the newly created Nebraska Territory for settlement. The Council Bluffs and Nebraska Ferry Company surveyed and laid out the site of Omaha. The firm sold land for $25 per lot. In 1855, the first territorial legislature selected Omaha as the

Greater Omaha Convention and Visitors Bureau

An outdoor concert in Omaha draws many people. The Joslyn Art Museum presents the free "Jazz on the Green" programs in the summer on its east lawn and grand staircase.

capital. Omaha was incorporated as a city in 1857.

In the late 1850's, Omaha became an outfitting point for wagon trains headed for the newly discovered gold fields of Colorado. But the city grew slowly and, in 1860, had a population of only 1,183.

Many Nebraskans had opposed the selection of Omaha as the territorial capital. More than half the territory's people lived south of the Platte River. They felt that the capital should not be north of the Platte, as Omaha is. After Nebraska became a state in 1867, the city of Lincoln was chosen as the new capital. The state government moved to Lincoln, 50 miles (80 kilometers) southwest of Omaha, in 1868.

In 1863, President Abraham Lincoln had selected the Council Bluffs area as the starting point of the Union Pacific Railroad. In 1865, the first tracks were laid westward from Omaha. The Union Pacific thus became part of the first U.S. transcontinental rail system, which was completed in 1869. Omaha began to grow rapidly and had 16,083 people by 1870.

During the 1880's, Omaha developed into an important meat-processing center. The city's location in a great cattle-raising area and at the heart of a rail network helped this growth. The opening of the Union Stockyards in 1884 hastened the growth. Thousands of immigrants, many from southern and central Europe, worked in Omaha's meat-packing plants.

In 1898, the Knights of Ak-Sar-Ben organized the Trans-Mississippi and International Exposition, which attracted more than $2\frac{1}{2}$ million visitors to Omaha. By 1900, the city had 102,555 people. The population reached 191,601 in 1920, and 223,844 in 1940. The number of factories grew from 150 in 1900 to 450 in 1950. In 1948, the U.S. Air Force established the headquarters of the Strategic Air Command (SAC) at Offutt Air Force Base, near Omaha. SAC was eliminated in 1992 during a reorganization of the Air Force. The base is now the headquarters of the U.S. Strategic Command.

Changes in the city during the last half of the 1900's included turning a wholesale fruit and vegetable market south of the downtown area into a visitor attraction called Old Market. Old Market is a brick-paved district with shops, art galleries, and restaurants. Other projects included the construction of a hotel and several large office buildings in downtown Omaha. The Central Park Mall also was completed. The mall links the city's business district to the riverfront.

In 2001, construction began on a new convention center and arena on the northeast edge of the downtown area. Completion was scheduled for 2003.

Lawrence H. Larsen

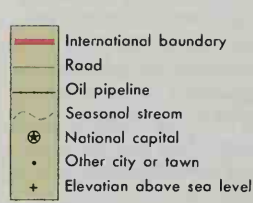
For the monthly weather in Omaha, see **Nebraska** (Climate). See also **Nebraska** (pictures).

Omaha Indians live mainly in northeast Nebraska. Many make their homes on a reservation there. Many others live in Lincoln or Omaha or in Sioux City, Iowa. The city of Omaha was named after the Omaha Indians.

The Omaha once lived in the Ohio River Valley along with ancestors of the Kansa, Osage, Ponca, and Quapaw Indians. They all spoke similar Siouan languages. Eventually, the groups separated, and most of them moved west. The Omaha arrived in Nebraska about 1700. Many Omaha still speak their own language.

In Nebraska, the Omaha traditionally lived in *earth lodges* in villages near the Missouri River. An Omaha earth lodge consisted of a circular log frame covered with layers of branches, grass, and earth. The Omaha planted corn and other crops in the spring. In summer, they moved west to hunt buffalo and lived in tepees. In the fall, they returned to the village with supplies of dried buffalo meat and harvested their corn. They hunted deer in the winter. John Ludwickson

Oman, *oh MAHN,* is a small country on the southeastern end of the Arabian Peninsula. Most of the land is desert, but it holds large deposits of petroleum. Muscat is Oman's capital and largest city.



Oman lies on the Gulf of Oman and the Arabian Sea. The country is bordered by Yemen on the southwest and Saudi Arabia on the west. The northern tip of Oman, the Musandam Peninsula, is separated from the rest of the country by the United Arab Emirates. The peninsula lies on the strategic Strait of Hormuz. This narrow waterway separates the Persian Gulf from the Indian Ocean, which opens to the east of the Gulf of Oman. All oil exported by ship from the Persian Gulf must pass through the strait.

Oman was extremely poor until oil was discovered there in 1964. The government has used oil revenues to finance economic improvements, and the standard of living of the population has risen. Nevertheless, most Omanis still struggle to earn a living.

Government. Oman is ruled by a monarch called the *sultan.* The sultan appoints cabinet members who oversee the operations of the government. Two councils advise the sultan. The sultan appoints the 41 members of the Council of State. He chooses the 82 members of the Consultative Council from among candidates elected by voters in each of Oman's 59 *wilayats* (districts). Oman has a Chief Court and local courts. All judges are experts in Islamic law.

People. Most of the population is Arab, and these people belong to various tribal and religious groups.

Oman

WORLD BOOK maps

Facts in brief

Capital: Muscat.
Official language: Arabic.
Official name: Saltanat Uman (Sultanate of Oman).
Area: 82,030 mi² (212,457 km²). *Greatest distances*—north-south, 500 mi (805 km); east-west, 400 mi (644 km). *Coastline*—about 1,060 mi (1,700 km).
Elevation: *Highest*—Jabal Ash Sham, 9,957 ft (3,035 m) above sea level. *Lowest*—sea level.
Population: *Estimated 2002 population*—2,711,000; density, 33 per mi² (13 per km²); distribution, 72 percent urban, 28 percent rural. *1993 census*—2,018,074.
Chief products: *Agriculture*—alfalfa, bananas, coconuts, dates, limes, onions, pomegranates, tobacco, tomatoes, wheat. *Fishing industry*—abalone, anchovies, cod, sardines, sharks, tuna. *Mining*—petroleum, natural gas, copper, chromite.
National anthem: "Nashid as-Salaam as-Sultani" ("Sultan's National Anthem").
Flag: The flag has a vertical red stripe and three horizontal stripes of white, red, and green. The national emblem, which features crossed swords and a dagger, appears at the top of the vertical stripe. See **Flag** (picture: Flags of Asia and the Pacific).
Money: *Basic unit*—Omani rial, or riyal. One thousand baizas equal one rial. See also **Rial**.

The largest of the many non-Arab minorities who live in Oman are Baluchis—that is, people from the Arabian Sea coast of Iran and Pakistan—and Asian Indians. The country's official language is Arabic.

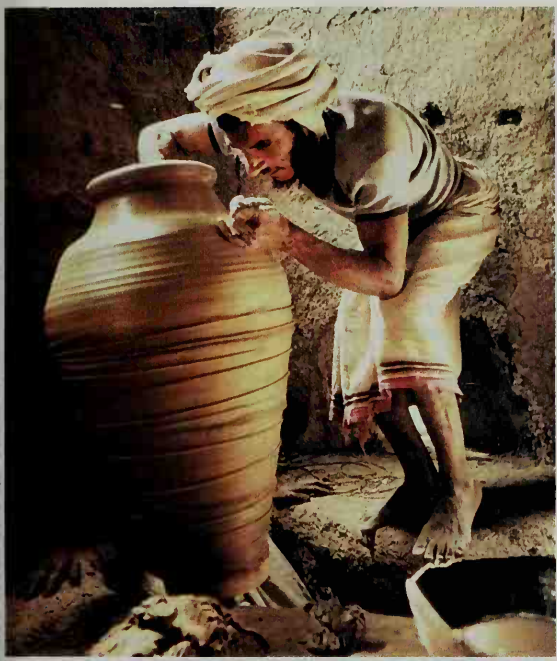
Most rural Omanis live in villages. Most people who live in coastal villages work on date palm plantations. Some fish for a living. Farmers in the interior villages grow dates, fruits, and grain. Some also raise animals.

Old Omani houses in coastal villages are made of palm leaves to allow the sea breezes to cool them. Old houses in villages in the interior are built of mud brick and stone. Newer housing is constructed from cement blocks. Some major towns have large stone fortresses that were built hundreds of years ago and beautifully decorated palaces where prominent families once lived.

Nomads make up about 5 percent of Oman's population. Nomads move from place to place as they search for water and grazing for their herds of goats, camels, and small cattle. They live in tents.

Omanis depend on wells for water for most or all of the year. Before the Arabs took over Oman, Persians lived there and built canals called *aflaj* (singular *falaj*) to carry water to the villages. Many aflaj carry water from underground wells tapped by tunnels called *qanat*.

Growing numbers of urban Omanis have jobs in industry, including the petroleum industry. Most city dwellers, however, are government workers, laborers, merchants, or sailors. Their houses are generally built of whitewashed mud brick. These houses are built around a central courtyard, and many have flat roofs surrounded by high walls. Some people sleep on these roofs during hot weather. The larger cities also have modern high-rise buildings.



Most Omanis are Muslims. Many belong to the moderate Ibadi (also spelled *Ibadhi*) branch of the Kharijite division of Islam. Ibadi Muslims have traditionally believed that the religious leader, the *imam*, should be elected based on merit. See **Islam** (Divisions of Islam).

The lives of most Omani women center on their homes and families. They follow Islamic religious rules about modest dress. When Omani women leave their houses, they wrap themselves in long black cloaks called *abayyas*, and some also wear black masks called *burqas* to cover their faces. These garments also protect them from the sun. Many Omani men wear a long white robe called a *dishdasha*. They often carry decorative knives called *khanjars*, which they wear in brightly colored sashes. In rural areas, some men carry rifles.

Since 1970, the government has built many schools for children and has established literacy programs for adults. Because of these efforts, the number of Omani people 15 years old or older who can read and write is rising. Sultan Qaboos University, the first university in Oman, opened in the Muscat region in 1986.

Land and climate. Most of Oman is dry and rocky. The Musandam Peninsula in the north consists of barren mountains. Al Batinah, a narrow coastal plain, lies along the Gulf of Oman. Date palms thrive in this fertile region.

Steep, rugged mountains called Al Hajar separate the Batinah from the interior. The interior is a vast, flat wasteland. The Rub al Khali (Empty Quarter), a desert, extends into western Oman from Saudi Arabia. Most of Oman's coast along the Arabian Sea is barren and rocky. But tropical vegetation grows along the coast in Dhofar,

© Robert Azzi, Woodfin Camp, Inc.

An Omani craftsman uses a potter's wheel to make pottery. Like most Omani men, this potter wears loose, white garments and a turban for protection from Oman's strong sun.

© David Hume Kennerly, Gamma/Liaison

Barren wasteland covers much of Oman. In this wasteland, farmers struggle to earn a living by grazing cattle or other livestock. Life in rural Oman has changed little through the years.

a region in the south. Dhofar is famous for its frankincense trees, the best of which grow on a plateau north of the Jabal al Qara, a mountain range.

Temperatures in Oman may reach 130 °F (54.4 °C) in the summer. Most of Oman receives less than 6 inches (15 centimeters) of rain each year. Dhofar, however, receives up to 25 inches (63.5 centimeters) of rain annually.

Economy. Oil exports provide the major portion of Oman's national income. However, many Omanis work in traditional occupations, such as farming and fishing. Chief crops, some of which are exported, include alfalfa, bananas, coconuts, dates, limes, wheat, and vegetables. Nomads and some settled farmers raise camels, cattle, goats, and sheep. Oman's fishing fleet catches sardines, sharks, tuna, and other fish and shellfish.

Oman's chief imports include manufactured goods and equipment needed for its industries. The nation's main trading partners are Japan, the United Arab Emirates, and the United Kingdom.

History. Human beings have lived in Oman for more than 5,000 years. Beginning in ancient times, Oman's wooden sailing ships carried goods throughout the Persian Gulf and to coastal areas in south Asia and east Africa. In the 1500's, Portuguese military forces built forts in Muscat and other Omani seaports as well as elsewhere in the Persian Gulf to control this rich trade. The Omani navy and tribal fighters, under the leadership of Sultan bin Saif al-Yaribi, forced the Portuguese from Oman in 1650. The Omanis then attacked rival shipping on the high seas and established control over trading ports along much of the east coast of Africa.

For centuries after the arrival of Islam in Oman during the 600's, members of the Ibadi branch of the faith had come into repeated conflict with the dynasties and foreign powers ruling Oman. In the 1740's, Ahmad bin Said, the first ruler of the Al Bu Said family, united the Omanis and took power. Ahmad died in 1783. Oman was then increasingly divided between the hereditary Al Bu Said rulers, whose power was based in coastal Muscat, and the more traditional Ibadi tribes of the country's interior, who looked to elected imams for leadership.

In 1798, the sultan signed the first of several treaties with the United Kingdom. The British competed against Oman for trade dominance in the Indian Ocean. Gradually, Oman's sea trade declined and its economy suffered. Oman also lost control of its outposts in the east.

Oman was reunited in 1955 by Sultan Said bin Taimur. With British help, the sultan defeated rebellious Ibadi tribesmen of interior Oman in 1959. In the early 1960's, another rebellion against Said began in Dhofar. In 1970, Said's son Qaboos bin Said overthrew him. Qaboos put down the Dhofar rebellion in the mid-1970's.

Said had been opposed to making Oman a modern state. Qaboos, however, immediately started to modernize the country. He developed the oil industry. He also constructed new irrigation systems and made many other agricultural improvements. He built roads, schools, and hospitals. Before Qaboos became sultan, few Omani children—and hardly any girls—ever went to school. Qaboos has encouraged Omanis to educate their daughters as well as their sons.

In 1981, Oman and five other Arab states bordering the Persian Gulf formed the Gulf Cooperation Council (GCC). GCC members work together on military defense and economic projects. Following Iraq's invasion of Kuwait in 1990, Omani military forces, as part of the GCC and the allied coalition, took part in the 1991 ground campaign that liberated Kuwait. Mary Ann Tétreault

See also **Gulf Cooperation Council; Muscat.**

Omar. See Muhammad (His religious life).

Omar Khayyam, *OH mahr ky YAHM* (1048-1131), was a Persian poet, astronomer, and mathematician. He was famous during his lifetime for his reform of the Islamic calendar. About 100 years after his death, collections of poems appeared bearing his name. These poems express religious skepticism and a rather world-weary *hedonism* (love of pleasure). The verses show a mind acutely conscious of human ignorance and of the brev-

ity of life. A collection called the *Rubaiyat of Omar Khayyam, The Astronomer-Poet of Persia* first attracted attention in the West in 1859, when English writer Edward FitzGerald published his free translation of a number of the stanzas arranged as a continuous poem.

Omar Khayyam was born on May 18, 1048, in Nishapur, in what is now northwestern Iran. His name, which probably reflects an ancestor's trade, means *the tentmaker.* Dick Davis

See also **Rubaiyat; FitzGerald, Edward.**

Ombudsman, *AHM buhdz MUHN,* is a nonpartisan public official who investigates people's complaints about government officials or agencies. Most of an ombudsman's work involves complaints of unjust or harsh treatment of people by police, prosecuting attorneys, or judges, and such matters as housing, taxation, voting, or welfare payments. After investigating a complaint, the ombudsman may dismiss it or may seek correction of the problem—by persuasion, by publicity, or, occasionally, by recommending prosecution.

The idea of the ombudsman originated in Sweden in 1809 and spread to other countries. Today in the United States, Hawaii has a comprehensive ombudsman plan, and other states and some cities have modified plans. The idea also has gained popularity in large organizations, including corporations and universities. The ombudsman's growing popularity coincides with the increasing complexities of administration and with people's need for impartial and informal handling of complaints. David R. Berman

Omdurman, *AHM dur MAHN* (pop. 526,827), is the largest city in Sudan. It lies on the west bank of the Nile River, across the river from Khartoum, Sudan's capital. For location, see **Sudan** (map).

Omdurman is a regional market. It is also a religious and cultural center for Sudanese Muslims. The tomb of Muhammad Ahmed, a Muslim leader called the *Mahdi* (divinely appointed guide), stands in the city center. Muhammad Ahmed founded the city in 1885. Near the tomb is a large market area called the *suq.* Many people who work in Khartoum live in Omdurman. Omdurman has modern apartment buildings and houses. It also has small houses made of sun-dried mud-brick. Tents and shacks on the outskirts of the city provide shelter for many refugees from western and southern Sudan and nearby countries. Kenneth J. Perkins

Omen is supposedly a sign of future good or bad luck. A good omen foretells a desirable event, and a bad omen forecasts disaster. For example, a person may regard a dream about gold as an omen of success in business. Or the person may believe that the death of a relative will follow a dream about losing a tooth. Sometimes omens come from a deliberate attempt to look into the future, such as a fortuneteller's "reading" cards.

Many ancient societies believed that lightning, thunder, or the behavior of animals foretold events. For example, the Mesopotamians thought fire would destroy the king's palace if a dog were seen lying on the throne. In Greece, the cry of a hawk warned of danger. Many leaders, when trying to decide on a course of action, asked the gods for a sign. In folklore, many heroes die after disregarding such signs. Alan Dundes

See also **Augur; Divination; Superstition.**

Omnibus bill, *AHM nuh buhs,* is a term which is sometimes used for a bill that includes several unrelated measures when it is put before a legislative assembly. It is used to pass several bills at once. It is named for an *omnibus* (bus), a vehicle that carries a number of people.

Omnibus bills are considered bad practice. When a number of unrelated items are crowded into one bill, it is hard to give each the study it deserves. In addition, an omnibus bill may include provisions that would be unlikely to pass on their own merits. Sometimes, legislators attach an amendment called a *rider* to an important bill. Opponents are forced to accept the rider if they want the rest of the bill to become law. The constitutions of most states and provinces provide that a single bill shall relate to one topic only. Douglas Greenberg

Omsk, *awmsk* (pop. 1,157,600), is a major manufacturing center of Russia. It lies along the Irtysh River, about 1,360 miles (2,190 kilometers) east of Moscow, in Siberia (see **Russia** [political map]). Omsk is one of the largest cities in Siberia.

Omsk manufactures farm machinery for the surrounding agricultural area. The city also has large food-processing, oil-refining, and petrochemical industries.

Omsk was founded in 1716, during the Russian expansion into Siberia. The Trans-Siberian Railroad reached the city in 1894, and Omsk became a commercial center of western Siberia. During World War II (1939-1945), the government moved many factories from combat zones in the western part of Russia to safe areas in Siberia. Omsk developed rapidly as a result, and its industries have continued to expand. Zvi Gitelman

Onager, *AHN uh juhr,* is the name of a fast-running animal which is a relative of the donkey. It is the *wild ass* mentioned in the Bible. The onager travels in herds on the hot, dry plains of west-central Asia. Its color varies from cinnamon-brown in summer to yellow-brown in winter. A yellow patch covers each thigh and a broad black stripe runs along its back. The onager also has a mane and a tuft of hair at the end of its tail. It stands about 4 feet (1.2 meters) tall at the shoulder.

Steven D. Price

Scientific classification. The onager belongs to the horse family, Equidae. The scientific name for the onager is *Equus hemionus.*

Kenneth W. Fink, Bruce Coleman Inc.

Onagers resemble donkeys but run as swiftly as horses. This onager stands with her foal.

Jacqueline Kennedy Onassis

Onassis, Jacqueline Kennedy (1929-1994), the wife of President John F. Kennedy, was one of the most popular first ladies in United States history. President Kennedy was assassinated in 1963. Five years later, Mrs. Kennedy married Aristotle Onassis, a Greek businessman.

Jacqueline Kennedy Onassis was born in Southampton, New York. Her maiden name was Jacqueline Lee Bouvier. She graduated from George Washington University in 1951. From 1951 to 1953, she worked for the *Washington Times-Herald,* where she produced a daily column as an inquiring photographer. She asked people human-interest questions, such as whether they had done their Christmas shopping, and wrote up the replies. She took pictures of the people, which accompanied the column.

In 1953, Jacqueline Bouvier married Kennedy, who was then a U.S. senator. The couple had two children who survived infancy: Caroline, born in 1957; and John F., Jr., 1960. A daughter was stillborn in 1956, and a son born prematurely in 1963 lived only two days. Kennedy became president in 1961. As first lady, Jacqueline—who was often called "Jackie"—became known for her elegance in hairstyle, clothing, and other elements of fashion. She also won admiration for her composure and dignity following the assassination of her husband on Nov. 22, 1963.

Jacqueline Kennedy married Onassis in 1968. He died in 1975. From 1975 until her death, Jacqueline worked as an editor for book publishers. Kathryn Kish Sklar

Oñate, *oh NYAH tay,* **Juan de** (1550?-1626?), was a Spanish explorer. He is remembered mainly for colonizing the territory now called New Mexico in 1598. His explorations extended from the Colorado River to the plains of Kansas. Oñate served as governor of the territory but quarreled with the settlers and was forced to resign in 1607. He was tried and found guilty of immorality and abuse of power. It was largely due to Oñate that the city of Santa Fe was founded in about 1610. Oñate was born near Zacatecas, Mexico. Helen Delpar

Oncology, *ahng KAHL uh jee,* is the study of the development, treatment, and prevention of cancer. It includes both research and clinical care. Doctors who specialize in oncology are called *oncologists.*

In the laboratory, oncologists compare human cancer cells with normal cells to try to understand the cellular mechanisms that control the growth of normal tissues. By understanding these mechanisms, oncologists hope to find ways to correct abnormal tissue growth.

Similarly, oncologists study cancers in animals to learn how the body itself often controls the growth of cancer cells. The scientists study how naturally occurring chemicals called *interleukins* stimulate an animal's immune system to eliminate cancer cells. Through such research on animals, oncologists hope to develop methods of cancer prevention and treatment for people.

Clinical oncologists diagnose and treat cancer. A diagnosis is made by examining a piece of abnormal tissue under a microscope. This procedure, called a *biopsy,* determines if the tumor is cancerous. Treatment depends on whether tumors are limited to one site or organ in the body or whether cancer cells have spread. Surgery, radiation, drug therapy, or combinations of these treatments may be used (see **Cancer** [Cancer treatment]). Janice Phillips Dutcher

O'Neal, Shaquille, *sha KEEL* (1972-), is a star center in the National Basketball Association (NBA). O'Neal stands 7 feet 1 inch (216 centimeters) tall and weighs about 300 pounds (136 kilograms). He is known for his strength and for his powerful slam dunks. O'Neal consistently ranks among the NBA leaders in scoring, shooting percentage, rebounds, and blocked shots. He led the NBA in scoring in the 1994-1995 and 1999-2000 seasons. O'Neal won the league's Most Valuable Player award for the 1999-2000 season.

Shaquille Rashaun O'Neal was born in Newark, New Jersey. O'Neal attended Louisiana State University, leaving in 1992 after his junior year to turn professional. The Orlando Magic selected him as the first player in the 1992 NBA draft. He immediately became a dominant player and was named the league's Rookie of the Year for 1992-1993. In 1996, O'Neal signed as a free agent with the Los Angeles Lakers.

O'Neal has appeared in motion pictures and has recorded as a rap artist. His popularity has made him one of the most sought-after athletes for commercials and product endorsements. Sam Smith

O'Neale, Peggy (1796-1879), was a central figure in one of the greatest disputes in the history of Washington, D.C., society. The dispute caused President Andrew Jackson to reorganize his Cabinet.

Margaret O'Neale was born in Washington, D.C., the daughter of an innkeeper. Margaret, known by the nickname Peggy, married John B. Timberlake, a navy purser. She lived at the O'Neale tavern while Timberlake was at sea. Senator John H. Eaton of Tennessee lived there in 1818, and became fond of Peggy. Andrew Jackson, who became a U.S. senator from Tennessee in 1823, met Peggy at the inn. Peggy's husband died in 1828, and she married Senator Eaton on Jan. 1, 1829.

Eaton became secretary of war in 1829. Washington society refused to receive Peggy, because of her father's occupation and because of gossip about her conduct with Eaton. President Jackson stood by her, despite his family's protests. Several Cabinet members resigned, and Eaton resigned his post in 1831. James C. Curtis

Oneida Community, *oh NY duh,* a cooperative community in Oneida, New York, was founded by John Humphrey Noyes in 1848. Noyes hoped to make the community a *utopia* (perfect society). Noyes, a preacher, believed in a radical form of Christianity known as *Perfectionism.* Perfectionism taught that people could abolish sin from their lives and become perfect. Noyes began the community in Putney, but he and his followers were forced to leave because of their beliefs.

The members of the Oneida Community believed

that the best way to achieve perfection was to live communally, sharing the burden of labor as well as all possessions. The community abolished the private family and, in its place, set up a system called *complex marriage.* In this system, every man was considered to be married to every woman. The community also planned the birth of its babies and raised its children. In 1869, the community began to choose combinations of parents that it believed would produce the best children.

The Oneida Community flourished financially. It became wealthy by manufacturing and selling a type of steel game trap invented by one of its members. The community also earned money by canning and by manufacturing steel chains and silk thread.

In 1879, outside opposition to complex marriage forced the community to give up the practice. In 1881, the community was reorganized as a business corporation based on private ownership of stock. In the 1890's, the manufacture of silverware became the community's main industry. The community and silverware company still exist. But few of the voluntary cooperative features of the original community remain. Benjamin Zablocki

Oneida Indians. See **Iroquois Indians.**

O'Neill, Eugene Gladstone (1888-1953), is regarded as America's greatest playwright. In 1936, O'Neill received the Nobel Prize for literature. Four of his plays won Pulitzer Prizes—*Beyond the Horizon* in 1920; *Anna Christie* in 1922; *Strange Interlude* in 1928; and *Long Day's Journey into Night* in 1957, after his death.

O'Neill's plays show his fascination with philosophy and religion and his intense self-examination. By incorporating experimental techniques of European theater into his plays, O'Neill is credited with raising the previously narrow and insubstantial American drama into an art form that gained worldwide respect.

His life. O'Neill was born on Oct. 16, 1888, in New York City. His father, James O'Neill, was one of America's most popular actors. Between national tours, the family spent the summers in New London, Connecticut. Their home was the setting for two of O'Neill's greatest plays—*Ah, Wilderness!* (1933) and *Long Day's Journey into Night* (written from 1939 to 1941 and first performed in 1956). In New London, O'Neill discovered his mother's addiction to morphine and rebelled against his father's theatrical conservatism. O'Neill was raised a Roman Catholic, but he rejected religion. He married in 1909 but was divorced within three years. By 1912, he had worked as a gold prospector in Honduras and as a seaman and had become a frequenter of cheap saloons and flophouses in New York City. That year, he returned to New London and became ill with tuberculosis.

O'Neill's reading while recovering at a sanitarium inspired him to become a playwright. In 1914, he studied drama with George Pierce Baker at Harvard University. In 1916, O'Neill joined the Provincetown Players, an experimental theater group on Cape Cod in Massachusetts. In July, the group presented *Bound East for Cardiff,* the first staging of an O'Neill play.

O'Neill's second marriage, to writer Agnes Boulton, in 1918 ended in divorce in 1929. Later that year, he married actress Carlotta Monterey. He wrote until the mid-1940's, when a muscular disease resembling Parkinson disease prevented further work. O'Neill died largely forgotten. But in 1956, a revival of *The Iceman Cometh* (written in 1939) and the premiere of *Long Day's Journey into Night* aroused a renewed interest in his plays.

His plays. O'Neill's career consisted of two periods of realism divided by a middle period of experimentation. He first wrote one-act plays that utilized his youthful experiences, especially at sea. The best of these plays include four realistic works that trace the changing relationships among seamen of the S.S. *Glencairn* amid the tensions of World War I (1914-1918).

In the early 1920's, O'Neill rejected realism and determined to capture on stage the "force behind" human life. He was influenced by the ideas of the German philosopher Friedrich Nietzsche, the Austrian psychologist Sigmund Freud, the Swiss psychologist Carl Jung, and the Swedish playwright August Strindberg.

In *The Emperor Jones* (1920), an expressionistic play, O'Neill traced the personal and racial past of a black porter who becomes a Caribbean dictator. *The Hairy Ape* (1922) blends realistic and expressionistic elements in the story of an alienated man's attempts to belong in modern society. *Desire Under the Elms* (1924) transplants the Greek myth of Phaedra and Hippolytus and elements of other myths to a New England farm.

In *The Great God Brown* (1926), the characters wear masks that express or hide their inner natures. In the nine-act *Strange Interlude* (1928), characters voice inner thoughts that frequently contradict their public utterances. *Mourning Becomes Electra* (1931) is a trilogy that shifts the Greek tragic trilogy the *Oresteia* to America immediately after the Civil War (1861-1865). The gods and Furies of Greek mythology are replaced by the workings of the subconscious mind.

O'Neill's final period was his best as he returned to realism and the more open acknowledgment of a lifelong impulse to write autobiographical plays. *The Iceman Cometh* immortalizes the unrealistic "pipe dreams" of the friends from the flophouses and Greenwich Village. The play's characters shield themselves from the bitter truth of failure through their mutually supportive illusions. *A Touch of the Poet,* written from 1935 to 1942 and first staged in 1957, is the only complete drama of a planned 11-play cycle. O'Neill intended the cycle to trace the life of an Irish American family and the spiritual decline of America from the early 1800's. In his greatest play, *Long Day's Journey into Night,* the Tyrone family is clearly based on O'Neill's own family in 1912. *A Moon for the Misbegotten* (written from 1941 to 1943 and first performed in 1957) is a sequel that portrays the last days of O'Neill's alcoholic brother, Jamie.

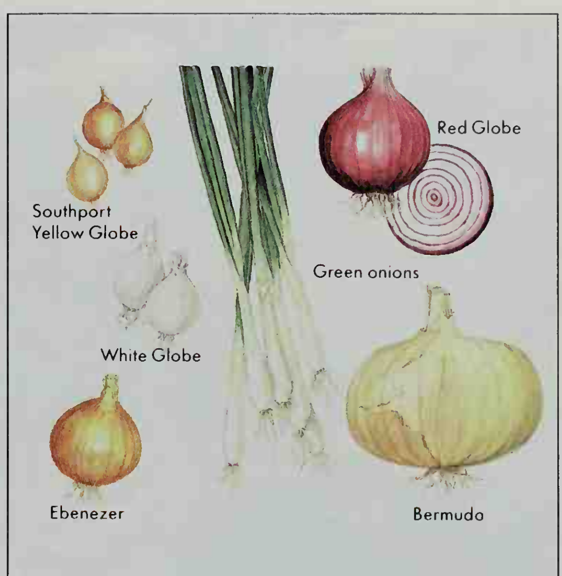
O'Neill, Thomas Philip (1912-1994), a Massachusetts Democrat, served as speaker of the United States House of Representatives from 1977 until 1987, when he retired. His retirement ended a 34-year career in the

House. O'Neill had served as majority *whip* (assistant leader) of the House from 1971 to 1973 and as majority leader from 1973 to 1977.

O'Neill was born in Cambridge, Massachusetts. He graduated from Boston College in 1936 and was elected to the Massachusetts House of Representatives that same year. He became minority leader in 1947 and speaker of the Massachusetts House in 1948.

O'Neill won election to the U.S. House of Representatives in 1952. As a representative, he supported several changes in House rules. For example, he led a successful fight to record all votes in the House. Previously, representatives had voted on amendments to bills with no record of whether they favored or opposed the legislation. In 1967, O'Neill became one of the first House leaders to publicly oppose United States involvement in the Vietnam War. Guy Halverson

Onion is a vegetable that has a strong odor and flavor. Onions rank as one of the world's most popular foods. They are used chiefly as a seasoning and are eaten raw, cooked, dehydrated, and pickled. When cut, raw onions give off a vapor that causes people's eyes to water.



The onion plant. Most onion plants are *biennials* (plants that require two years to complete their life cycle). When fully grown, they consist of leaves, a bulb, and roots. The long, slender leaves are hollow cylinders that grow upright. They thicken at the base to form a bulb, the part of the plant that people eat most frequently. Onion bulbs grow partially aboveground. They tend to be globe-shaped, but some are wide and flat and others are slender and upright. A thin papery covering made up of dried outer leaves encloses the bulb.

Onion bulbs may be red, white, or yellow. A cluster of short root fibers grows from the bottom of the bulb. During its second year of growth, an onion plant produces rounded clusters of small, greenish-white, seed-bearing flowers at the tips of its stalks. Most onions are harvested during the first year and thus do not flower.

Onions are classified as *short-day onions* or *long-day onions,* depending on the amount of daylight needed to begin bulb formation. Short-day onions require 10 to 11 hours of daylight and grow best in the Southern United States. Long-day onions need 14 to 15 hours and grow best in the northern part of the country. Varieties of short-day onions include Excel, Granex, Texas Early Grano, and Yellow Bermuda. Long-day varieties include Abundance, Elite, Epoch, Southport Yellow Globe, and Sweet Spanish. To form a bulb, all onion plants require an average temperature greater than 60 °F (16 °C).

Cultivation. Onion growers plant onion *sets* (small bulbs), seeds, or seedlings. Seedlings are grown in a greenhouse or in areas that have a warm climate during winter. Seeds are planted at a depth of about a $\frac{1}{2}$ inch (1.3 centimeters). Sets are pressed into the ground but left uncovered. Onions require rich soil. They also need plenty of water, especially when they are young. When the bulb is ready to be harvested, the plant's leaves become limp and fall over. To avoid decay, growers dry and store harvested bulbs in a cool place.

Onions differ in the strength of their flavor. People use such strong-tasting onions as the Southport Yellow Globe in soups and stews. Mild onions, including the Yellow Bermuda and Sweet Spanish, are often eaten raw in salads or on sandwiches. Onions harvested when their bulbs are immature are called *green onions* or *salad onions* and are sold with leaves attached.

WORLD BOOK illustrations by Kate Lloyd-Jones, Linden Artists Ltd.

The onion is a vegetable with a bulb that can be eaten raw or used in cooking. Onions come in many shapes, sizes, and colors. This illustration shows some common kinds of onions.

Onions probably first grew in central or southwestern Asia. Today, the leading onion-growing countries include China, India, and the United States. In the United States, leading onion-growing states include California, Oregon, and Colorado. George R. Hughes

Ontario

Ontario, *ahn TAIR ee OH,* has more people than any other Canadian province. About a third of Canada's people live in Ontario. Service industries provide Ontario with its greatest source of income. Ontario's manufacturing industries produce about as much as those of the nine other provinces combined. Ontario ranks first among the Canadian provinces in farm income and metallic mineral production.

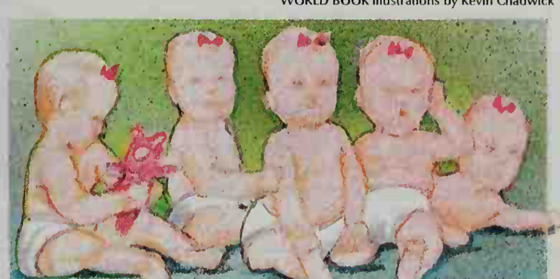
Toronto is the capital of the province, and the Toronto area is Canada's leading manufacturing center. Ottawa, the capital of Canada, lies on the Ottawa River in southeastern Ontario.

Ontario has a larger area than any other Canadian province except Quebec. It is the southernmost province, but it also extends so far north that some of the ground beneath the surface is *permafrost* (permanently frozen ground).

The contributors of this article are Walter G. Kemball, President of W. Kemball Curriculum Consultants Inc.; and John T. Saywell, University Professor and Professor of History and Social Science at York University.

The busy factories, mills, and plants of Ontario have given it the nickname *Manufacturing Heartland of Canada.* Most industries are in the warm southern region, south of Lake Nipissing. About 90 percent of the people live there, on about 12 percent of the land area. The province's richest manufacturing section, called the *Golden Horseshoe,* curves around the western shores of Lake Ontario.

Ontario's major industry is manufacturing automobiles. Most of the province's automobile plants are in the Golden Horseshoe. Almost all the automobiles made in Canada come from there. Hamilton, a city in the Golden Horseshoe, is Canada's greatest iron and steel center. Nearby is Toronto, one of the chief Canadian ports on the Great Lakes. The region's varied products travel from Toronto to many parts of the world by way of the St. Lawrence Seaway.



The mines of Ontario provide about a third of all the non-fuel minerals produced in Canada. Deposits near Greater Sudbury yield about one-eighth of the world's supply of nickel. One of the major known uranium deposits in the world lies near Elliot Lake. Ontario is also one of North America's leading producers of gold.

Dionne quintuplets

The Dionne quintuplets were born in a farmhouse near Callander in 1934. They were the first quintuplets known to live more than a few days after birth. All five girls were identical. There had been only two previous cases of identical quintuplets in medical history.

Insulin, a hormone that regulates the body's use of sugar, was discovered in 1921 at the University of Toronto by Frederick G. Banting, Charles H. Best, John J. R. Macleod, and James B. Collip.

The Ambassador Bridge connecting Windsor and Detroit, Michigan, is the world's longest international suspension bridge. It has a span of 1,850 feet (564 meters).

Ambassador Bridge

The CN (Canadian National) tower in Toronto is the world's tallest freestanding structure. The tower rises 1,815 feet (553 meters) and is used for broadcasting and observation.

Ontario is Canada's leading producer of eggs and poultry and also leads in the production of fruits and vegetables. It provides nearly a fourth of Canada's farm products. Herds of beef and dairy cattle graze in rich pastures between Lake Huron and Lake Ontario. Tobacco grows along Lake Erie, and orchards thrive in the Niagara fruit belt. Northern Ontario has thick forests that provide wood for the pulp and paper industry. Trappers catch fur-bearing animals there, and campers hunt and fish.

The province's name came from the Iroquois Indians, who lived in the Ontario region when French explorers first arrived. The word *Ontario* may mean *beautiful lake.* Or it may mean *rocks standing high* or *near the water*—referring to Niagara Falls. These spectacular falls attract many visitors. Niagara Falls ranks among the greatest natural sources of hydroelectric power in North America.

Ontario, together with New Brunswick, Nova Scotia, and Quebec, was one of the original provinces of Canada. For the relationship of Ontario to the other provinces, see **Canada; Canada, Government of; Canada, History of.**

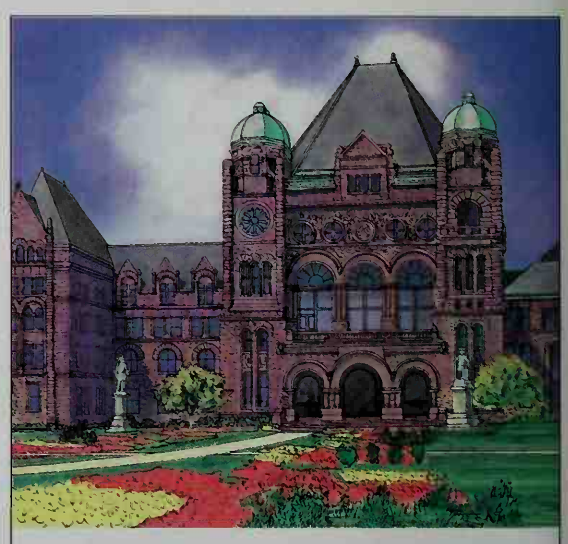
Ontario in brief

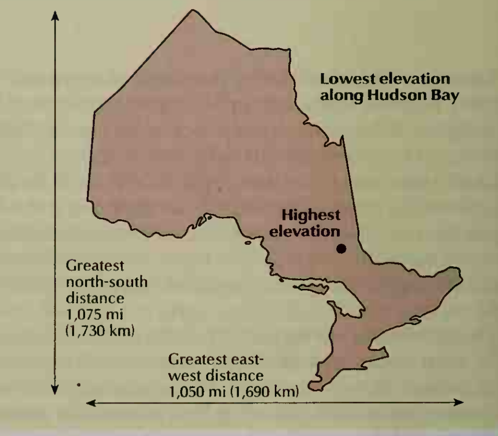
Symbols of Ontario



The provincial flag, adopted in 1965, bears the British Union Flag and the shield of Ontario. The shield has the cross of Saint George, representing the province's ties with the United Kingdom. The three maple leaves symbolize Canada. The crest is a bear atop a wreath of green and gold. A moose and a deer support the shield. The shield was granted by royal warrant in 1868. The crest and supporters were granted in 1909.

Provincial flag

Ontario (brown) ranks as the second largest province of Canada.



The Provincial Parliament Buildings are in Toronto, the capital since 1867. The region had several other capitals as Upper Canada and part of the Province of Canada.

General information

Entered the Dominion: July 1, 1867, as one of the original four provinces.
Provincial abbreviation: ON (postal).
Provincial motto: *Ut Incepit Fidelis Sic Permanet* (Loyal She Began, Loyal She Remains).

Land and climate

Area: 412,581 mi² (1,068,580 km²), including 68,491 mi² (177,390 km²) of inland water.
Elevation: *Highest*—2,275 ft (693 m) above sea level in Timiskaming District. *Lowest*—sea level.
Coastline: 752 mi (1,210 km).
Record high temperature: 108 °F (42 °C) at Biscotasing on July 20, 1919, at Atikokan on July 11 and 12, 1936, and at Fort Frances on July 13, 1936.
Record low temperature: −73 °F (−58 °C) at Iroquois Falls on Jan. 23, 1935.
Average July temperature: 66 °F (19 °C).
Average January temperature: 9 °F (−13 °C).
Average yearly precipitation: 31 in (79 cm).

Important dates

1610 Étienne Brûlé of France became the first white person to explore the Ontario region.

1639 French missionaries founded Fort Sainte Marie.

1763 Britain obtained the Ontario region from France.

1867 Ontario became one of the ori[ginal] four provinces on July 1.

Sources of information

For information about tourism in Ontario, write to: Ontario Travel, Queen's Park, Toronto, ON M7A 2E1. The Web site at www.ontariotravel.net also provides information on tourism in the province. For information on Ontario's economy, government, and history, write to: Citizens' Inquiry Bureau, Ferguson Block, 77 Wellesley Street West, 12th Floor, Toronto, ON M7A 1N3. The Ontario government's Web site at www.gov.on.ca also provides a gateway to much information on the province's economy, government, and history.

1883 The world's largest copper-nickel reserves were discovered at Sudbury.

1912 Ontario gained the territory north of the Albany River.

1952 One of the world's largest uranium deposits was discovered at Elliot Lake.

1972 Ontario began a program of free medical and hospital care for the elderly and the poor.

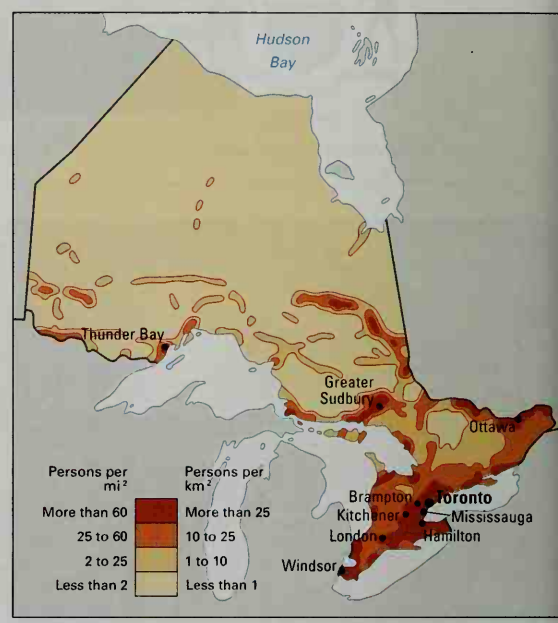
People

Population. The 2001 Canadian census reported that Ontario had 11,410,046 people. The population of the province had increased about 6 percent over the 1996 figure of 10,753,573.

The great majority of Ontarians—92 of every 100 people—live in 12 percent of the province's land area. This heavily populated region, the southernmost part of the province, lies south of Lake Nipissing. This area includes all of Ontario's metropolitan areas except those of Greater Sudbury and Thunder Bay.

Ontario has 11 Census Metropolitan Areas as defined by Statistics Canada. For the names and populations of these metropolitan areas, see the *Index* to the political map of Ontario.

More than four-fifths of the people of Ontario live in cities and towns. Ontario contains more cities with populations of 50,000 or more than any other Canadian province.



Toronto is the largest city in Ontario and in Canada. Ontario's other large cities include Brampton, Hamilton, London, Markham, Mississauga, Ottawa, and Windsor. See the list of separate articles on the cities of Ontario listed in the *Related articles* at the end of this article.

About three-fourths of the people in Ontario were born in Canada. The province also has many people born in Britain, Italy, the United States, and Germany. Nearly half of all Ontarians have some English ancestry. There are also many people with Scottish, Irish, and French ancestry.

Ontario has about 66,000 North American Indians. About 45 percent of the Indians live on the province's 186 reserves. These areas cover a total of 1 $\frac{3}{4}$ million acres (710,000 hectares) in the province. Another 154,000 of Ontario's people have some American Indian ancestry.

Population density

The vast majority of Ontario's people live in the southeast part of the province, where most of the largest cities are located. The northern areas of Ontario are thinly populated.

WORLD BOOK map; based on the *National Atlas of Canada.*

John Foster, Masterfile

Indians cut firewood on an Ontario Indian reserve. About 66,000 people in Ontario are North American Indians. About 45 percent of these people live on Indian reserves.

Ontario Ministry of Tourism and Recreation

Yorkville is a fashionable area of Toronto that features art galleries, boutiques, and sidewalk cafes. The district is also known for the variety of its architecture.

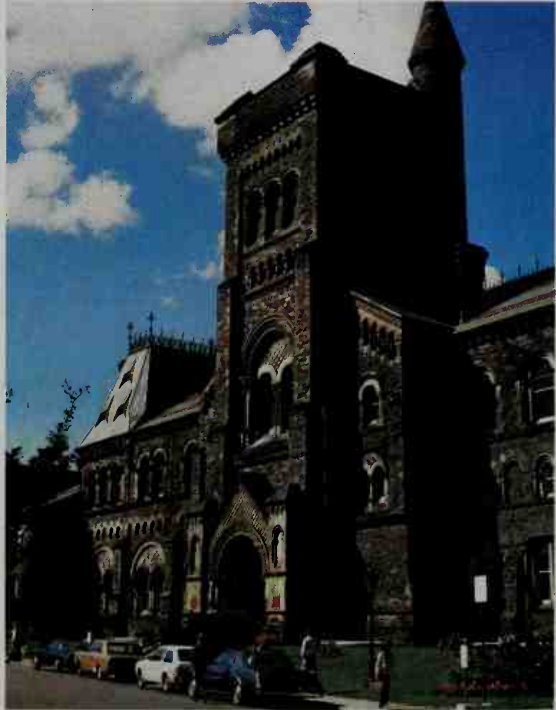
Schools. The first *common* (elementary) schools in the Ontario region were established during the late 1780's. In 1807, Ontario's provincial government provided by law for a *grammar* (high) school in each of the province's eight districts. In 1816, the government provided for common schools throughout the province. A royal charter was granted in 1827 for a college in York (now Toronto). This college opened in 1843 under the name of King's College and became the University of Toronto in 1850.

Ontario's school system took its present basic form during the 1870's. All common and grammar schools became free elementary and secondary schools. Attendance from age 6 to age 16 was required by law, as it still is today.

Today, Ontario has public schools and Roman Catholic schools. Both types of schools are tax supported, and both are under the jurisdiction of the Ministry of Education. English is the language of instruction in most schools. However, the province also has some French-language schools as well as a number of schools where both English and French are used. For the number of students and teachers in Ontario, see **Education** (table).

Libraries. Ontario's first subscription library was established in 1800 at Niagara. By 1867, when Ontario became one of the four original provinces of Canada, it had more than 60 *mechanics' institutes,* which provided books for working people. Ontario passed Canada's first public library legislation, the Free Libraries Act, in 1882. Today, the province contains hundreds of public libraries.

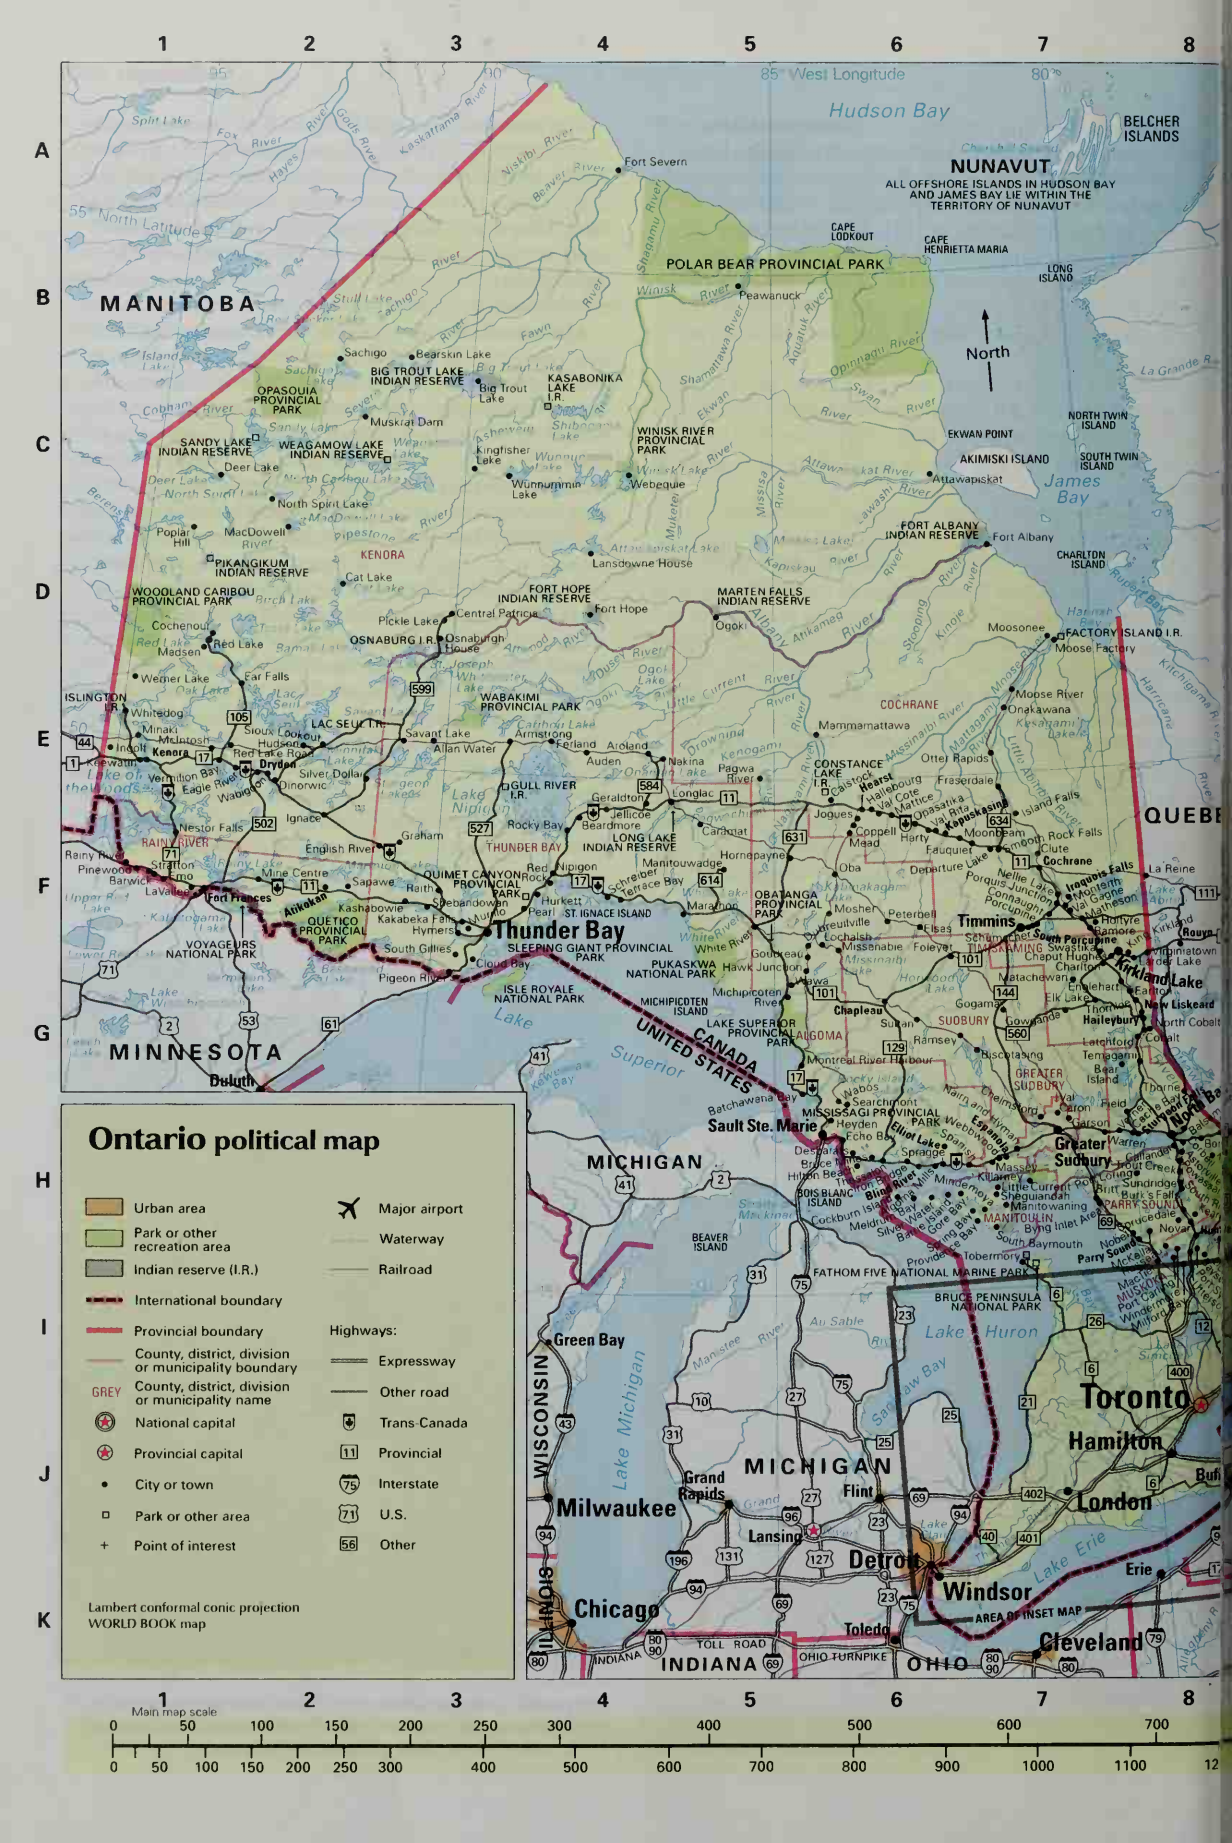
The National Library of Canada, the Canada Institute for Scientific and Technical Information, the Library of Parliament, and the Supreme Court of Canada Library are in Ottawa. The Thomas Fisher Rare Book Library of the University of Toronto includes well-known collections of Canadian, English, and Italian literature. The National Gallery of Canada Library, also in Ottawa, includes an extensive collection of visual-arts literature.



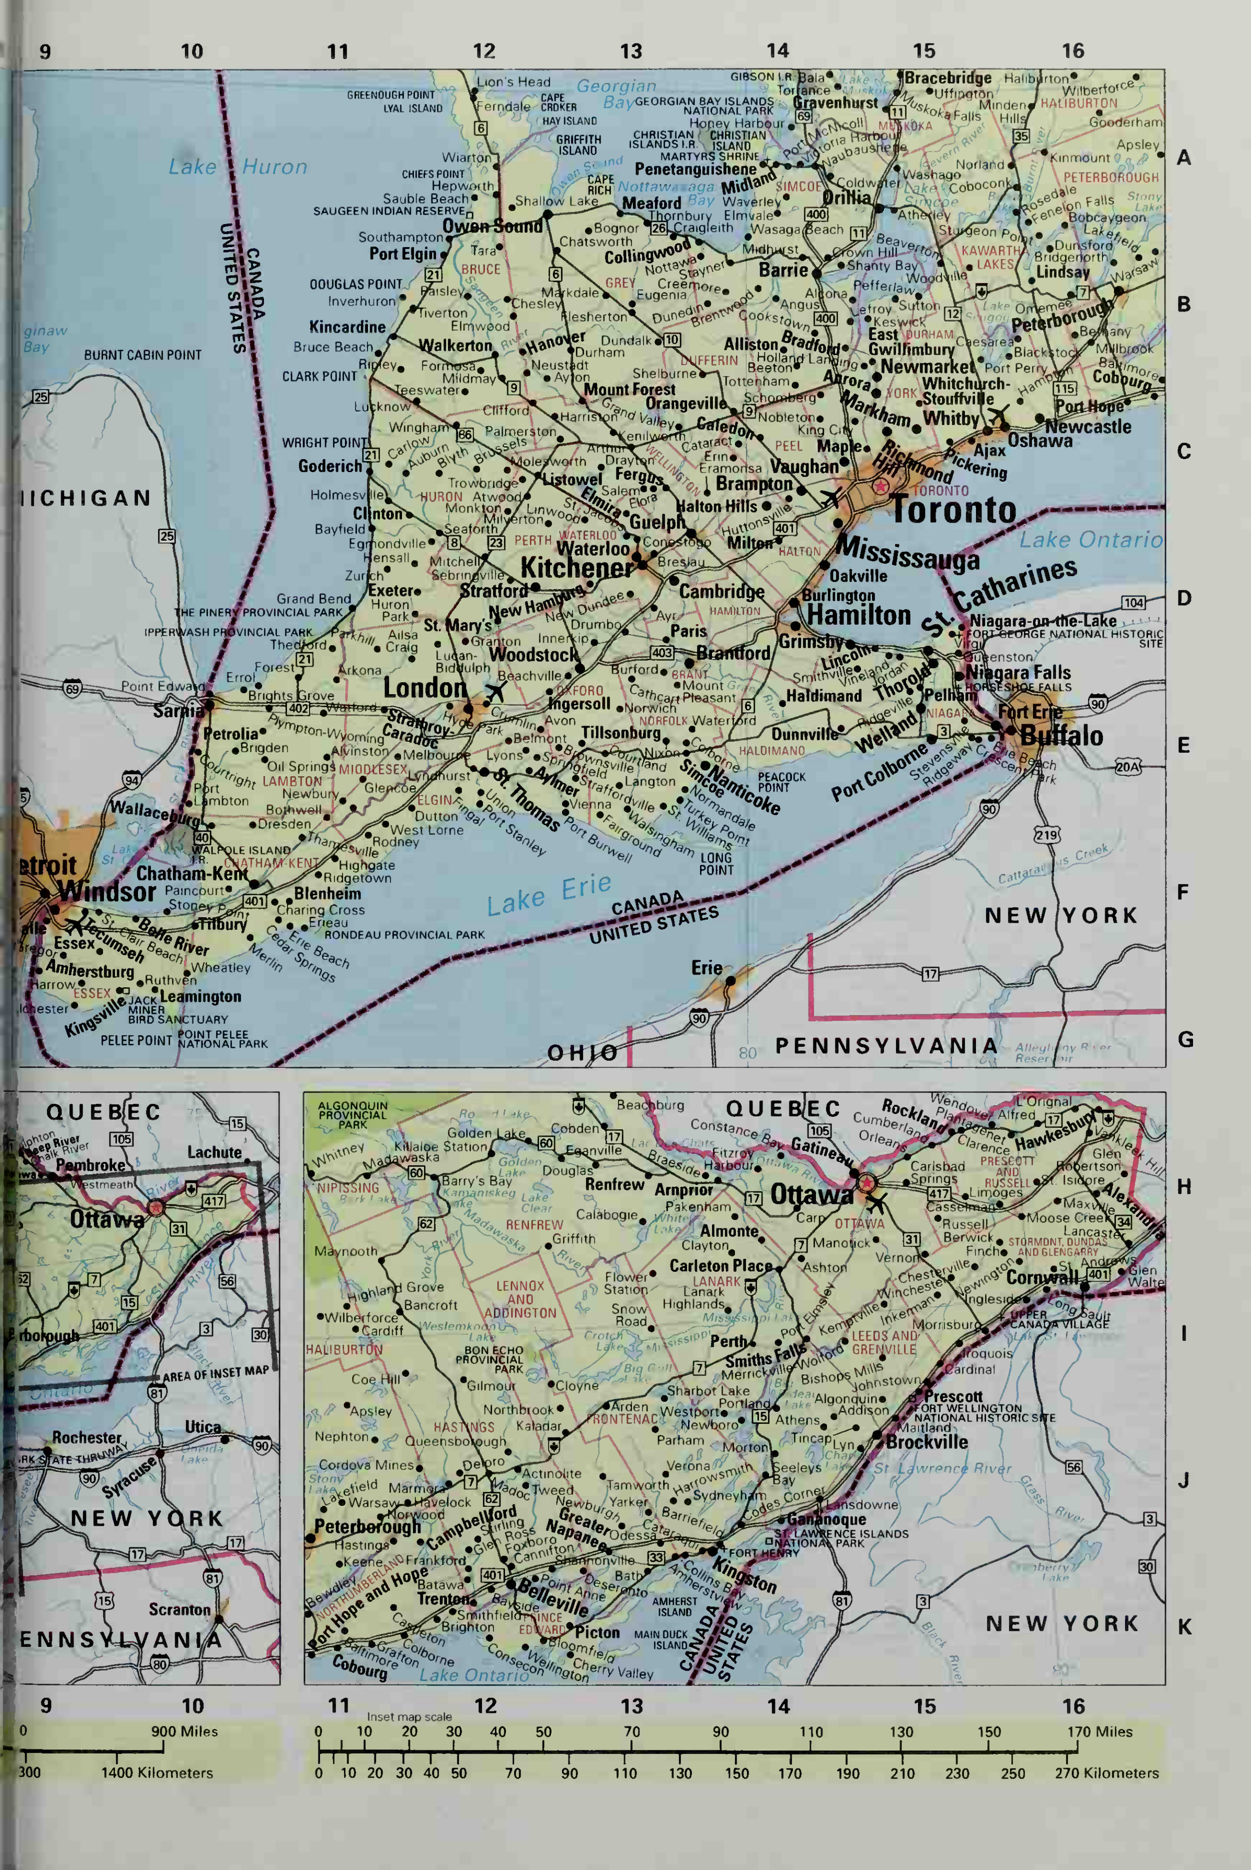
Museums. The Royal Ontario Museum in Toronto has more than 45 galleries containing archaeology, art, and science exhibits. The Ontario Science Centre, also in Toronto, features exhibits and demonstrations dealing with science and technology. National museums in Ottawa include the Canadian Museum of Nature, with collections covering botany, earth sciences, and vertebrate and invertebrate animals; the Canada Science and Technology Museum, with exhibits on astronomy, communications, outer space, technology, and transportation; and the National Gallery of Canada, which features artworks from Canada and other parts of the world.

Old Fort William in Thunder Bay is a reconstruction of a local fur-trading post of the 1800's. Sainte-Marie Among the Hurons, near Midland, is a re-creation of a fortress and headquarters for Jesuit missionaries of the 1600's. The fortress was Ontario's first European community. Ottawa's Canadian War Museum displays art, artifacts, and memorabilia representing the nation's military history. Many community museums throughout Ontario highlight local history and regional history.

Universities and colleges



This table lists the universities and colleges in Ontario that grant bachelor's or advanced degrees and are members of the Association of Universities and Colleges of Canada.



Name	Mailing address
Brescia College	London
Brock University	St. Catharines
Carleton University	Ottawa
Dominican College of Philosophy and Theology	Ottawa
Guelph, University of	Guelph
Huron University College	London
King's College	London
Lakehead University	Thunder Bay
Laurentian University of Sudbury	Sudbury
McMaster University	Hamilton
Nipissing University	North Bay

Visitor's guide

More than 20 million tourists visit Ontario every year. The province has more than 250,000 lakes and rivers, which offer a variety of vacation attractions, including fishing and boating. Ontario's forests attract campers and hunters.

The sunny, southernmost resort region of the province, along Lakes Erie and Ontario, is known as *Canada's Sun Parlor.* Boat cruises are available to take vacationers through the Thousand Islands and other islands in Ontario waters. The Haliburton Highlands and the Kawartha and Muskoka lakes near Toronto are famous resort areas. Low, wooded hills line their shores. The landscape becomes more rugged toward the northern and northwestern vacationlands of James Bay and Lake of the Woods. Many hunters fly in seaplanes to the far northern lakes to hunt bear, geese, moose, and a variety of other game.

Ontario is the home of two major annual drama festivals. The Stratford Festival, held in Stratford, features the plays of William Shakespeare. The Shaw Festival, at Niagara-on-the-Lake, presents plays by George Bernard Shaw and other dramatists of his time.

Horseshoe Falls, the largest part of Niagara Falls, near the Ontario-New York border

Places to visit

Following are brief descriptions of some of Ontario's many interesting places to visit:

Agawa Canyon, near Sault Ste.-Marie, is a scenic wilderness area with waterfalls, mountains, ravines, and forests.

Black Creek Pioneer Village, in Toronto, is an open-air museum that re-creates rural life in Ontario in the 1800's. The village includes houses, farm buildings, workshops, and an inn.

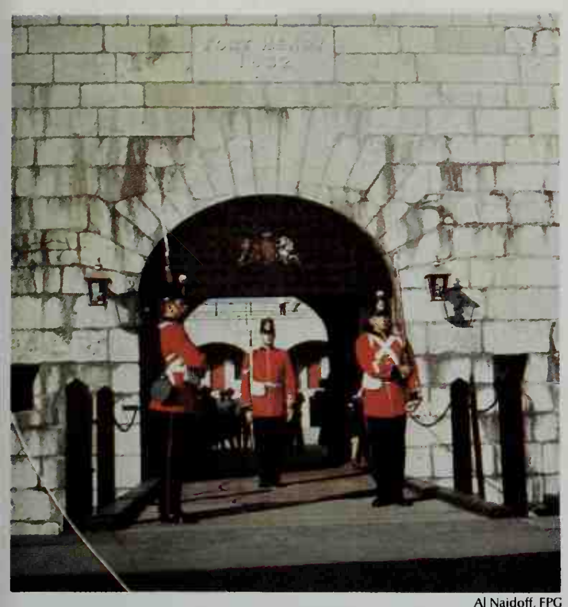
CN Tower, in Toronto, is the world's tallest free-standing structure.

Horseshoe Falls, near the Ontario-New York border, is the largest part of Niagara Falls. It is about 2,600 feet (792 meters) wide and 167 feet (51 meters) high.

Old forts in Ontario that have been restored include Fort Erie in Fort Erie, Fort George in Niagara-on-the-Lake, Fort Henry in Kingston, Fort Malden in Amherstburg, Fort St. Joseph on St. Joseph Island, Fort Wellington in Prescott, Fort York in Toronto, and Old Fort William in Thunder Bay.

Ontario Place, in Toronto, is a cultural, recreational, and entertainment complex that features concerts, a giant-screen movie theater, an exhibition area, and facilities for boating and picnics. It lies on artificially created islands in Lake Ontario.

Parliament Buildings, in Ottawa, are three Gothic-style stone buildings with green copper roofs. They form Canada's seat of government. The Changing of the Guards ceremony takes place in front of these buildings in July and August.



Royal Botanical Gardens, in Burlington, attract many visitors from around the world. The botanical gardens were established in 1941.

Sainte-Marie Among the Hurons, near Midland, is a reconstructed Jesuit mission of the 1600's. Martyrs' Shrine, which stands nearby, honors six missionaries who were martyred by the Iroquois.

Upper Canada Village, near Morrisburg, shows life in Ontario from 1784 to 1867. Some of its buildings were moved from the Lake St. Lawrence area.

National parks. Ontario has five national parks—Bruce Peninsula, between Lake Huron and Georgian Bay; Georgian Bay Islands, in Georgian Bay; Point Pelee, on the Lake Erie peninsula; Pukaskwa, on the shore of Lake Superior; and St. Lawrence Islands, along the St. Lawrence River. Ontario also has eight national historic parks and sites and one national marine park—Fathom Five in Georgian Bay. For the area and main features of the national parks in Ontario, see **Canada** (National Park System).

Provincial parks. Ontario has more than 250 provincial parks. Most provide camping facilities and waterside ramps for small boats. For information, write to: Ministry of Natural Resources, Ontario Parks, Whitney Block, #6540, 99 Wellesley Street West, Toronto, ON M7A 1W3. The Web site maintained by Ontario Parks at www.OntarioParks.com also has helpful information on provincial parks in Ontario.

Fort Henry in Kingston

Annual events

January-March
International Boat Show in Toronto (January); winter carnivals provincewide (January-February); Toronto Sportsman's Show (March); Maple Syrup Festivals throughout southern Ontario (March-April).

April-June
Shaw Festival in Niagara-on-the-Lake (April-October); Guelph Spring Festival (May); Canadian Tulip Festival in Ottawa (May); Stratford Festival (May-November); Heritage Festival in Timmins (June); Thunder Bay Children's Festival (June); Jazz Festival in Toronto (June); London Air Show and Balloon Festival (June).

July-September
International Freedom Festival, in Windsor and Detroit (July); Molson Indy automobile race in Toronto (July); Mariposa Folk Festival in Orillia (July); Festival of the Sound in Parry Sound (July-August); Caribana in Toronto (July-August); Rockhound Gemboree in Bancroft (July-August); Six Nations Native Pageant near Brantford (August); Canadian National Exhibition in Toronto (August-September); Toronto International Film Festival (September); Niagara Grape and Wine Festival in St. Catharines (September).

October-December
Oktoberfest in Kitchener-Waterloo (October); Royal Agricultural Winter Fair in Toronto (November); Niagara Falls Festival of Lights (November-January).

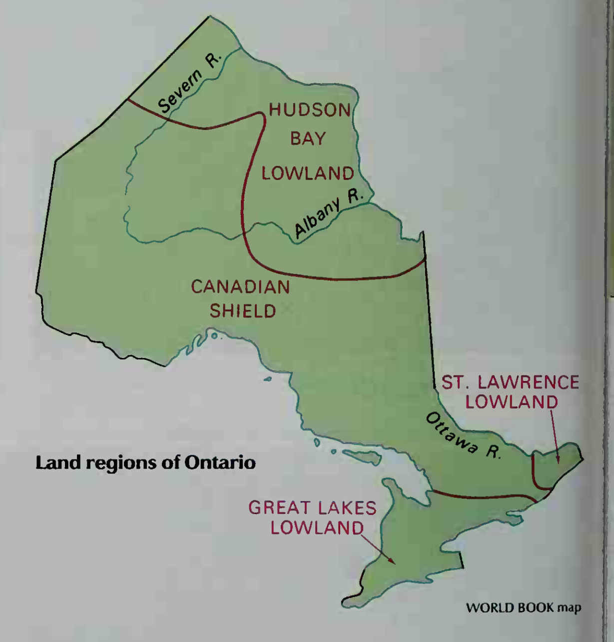
Thousand Islands area in the St. Lawrence River

Land and climate

The St. Lawrence Lowland is an important agricultural area. Fruits, grains, and vegetables are the chief crops grown in this fertile valley region between the Ottawa and St. Lawrence rivers.

Al Harvey, Masterfile

Land regions. Ontario has four main land regions. They are, from north to south: (1) the Hudson Bay Lowland, (2) the Canadian Shield, (3) the St. Lawrence Lowland, and (4) the Great Lakes Lowland.



The Hudson Bay Lowland curves around the southern part of Hudson Bay and extends as far south as Kesagami Lake. This flat region of northern Ontario is poorly drained, and has large *muskegs* (peat bogs). The lowland includes a narrow belt of *permafrost* (permanently frozen ground) near the Arctic.

The Canadian Shield is a vast, horseshoe-shaped region that covers almost half of Canada and part of the northern United States. This low, rocky region covers more than half of Ontario. Small lakes and rivers surrounded by wooded hills attract many vacationers. The highest point in Ontario rises 2,275 feet (693 meters) in Timiskaming District.

The Canadian Shield is rich in game, minerals, and timber. Patches of clay are scattered throughout the region. These areas were formed by deposits in ancient glacial lakes. The largest clay area, known as the clay belt, extends from the Hearst area to the Quebec border. Farmers raise a variety of crops, including grains and vegetables, in the rich clay soil. Beef and dairy cattle graze on fenced grasslands in the region. See **Canadian Shield**.

The St. Lawrence Lowland runs along the St. Lawrence River. In Ontario, it forms the tip of the wedge of land between the Ottawa and St. Lawrence rivers. Low hills rise above the fertile valleys. Farmers grow fruits, grains, and vegetables in this region. Dairy farming is extensive there.

The Great Lakes Lowland lies along much of the Great Lakes in Canada and the United States. In Ontario, the region touches Lakes Erie, Huron, and Ontario. Great quantities of many crops are grown in the fertile gray-brown soil of the low, flat, southwestern section. The land rises gently in the northeast, where beef and dairy cattle are raised. The Niagara Escarpment, a high cliff or ridge, extends 250 miles (402 kilometers) from Manitoulin Island, through Bruce Peninsula, to Niagara Falls. The escarpment forms a natural shelter for Ontario's best

Quetico Provincial Park, near Atikokan, is a large wilderness area of beautiful lakes and dense forests. Many people visit the park to enjoy camping, canoeing, and fishing.

fruit-growing belt. Many of Canada's largest cities are in the Great Lakes Lowland.

Shoreline and coastline. Ontario's southern shores of bays, narrow inlets, and sandy beaches stretch 5,252 miles (8,452 kilometers). This shoreline, including 2,414 miles (3,885 kilometers) of offshore island shoreline, is on Lakes Erie, Huron, Ontario, and Superior. Ontario's Manitoulin Island is the world's largest inland island. It has an area of 1,067 square miles (2,765 square kilometers) in Lake Huron.

Oceangoing ships use the St. Lawrence Seaway to reach the Great Lakes ports of Ontario. These inland seaports include Hamilton, Port Colborne, Sarnia, Sault Ste. Marie, and Toronto. Thunder Bay on Lake Superior is a major Canadian grain port. Northern Ontario has a coastline of 752 miles (1,210 kilometers) on Hudson Bay and James Bay.

Rivers, waterfalls, and lakes cover a sixth of the province. A land rise separates the Ontario streams that flow into the Great Lakes from those that empty into the Ottawa River or Hudson Bay. Many lakes and rivers, some linked by canals, are important transportation routes.

The St. Lawrence River, a great natural highway for commerce, has contributed much to the growth of Ontario's economy. This waterway was enlarged during the 1950's to allow ocean vessels to reach the Great Lakes. Hydroelectric plants on the Niagara and other rivers provide Ontario with cheap power. The mighty Horseshoe Falls are formed by the Niagara River passing over the Niagara Escarpment.

The Ottawa River was part of the route of the early fur traders to Georgian Bay and the west. This river flows into the St. Lawrence River. The Ottawa drains the part of southern Ontario that does not lie in the Great Lakes basin. Other important southern rivers include the French, Grand, Thames, and Trent. The Detroit and St. Clair rivers are links between Lakes Erie and Huron. Lakes Huron and Superior are joined by the St. Marys River.

Ontario has about 400,000 lakes. Besides the Great Lakes, the largest lakes in the province are Lake of the Woods, Lake Abitibi, Lake Nipigon, Lake Nipissing, and Lake Seul.

Plant and animal life. Ontario has about 180,000 square miles (466,000 square kilometers) of forests. Northern Ontario has huge forests of balsam, pine, spruce, and other softwoods. It also has birch and poplar. Thick forests of hardwoods such as ash, beech, elm, maple, and walnut once covered the southern part of the province. Most of the timber in the south was cut during the 1800's, and the forests there now have second-growth trees.

Wild flowers are plentiful in Ontario. Trilliums and bloodroots blossom in spring. Autumn brings masses o asters and wild carrot blooms. Northern lakeside hills are thick with wild blueberry bushes in forest clearings. Shrubs and mosses grow in the far northern areas, where frost stays deep in the ground. Tamarack and spruce, which grow there, do not reach their usual height in this cold, poorly drained region.

Moose and caribou roam the wooded northlands of Ontario. Shy white-tailed deer pause to drink from streams in the Canadian Shield. People in this region often see the tracks of black bears. Fur-bearing animals such as beavers, minks, muskrats, foxes, and otters live throughout Ontario. Snowshoe hares are also plentiful in all parts of the province. Raccoons and rabbits are abundant in southern Ontario. Birds of Ontario include ducks, geese, and ruffed grouse. The haunting cries of loons pierce the air at dusk over Ontario's lakes. Brook trout, lake trout, northern pike, whitefish, and yellow pickerel are found in the lakes and rivers.

Climate. Winds from the Great Lakes give southern Ontario a milder climate than the rest of the province. Northern Ontario gets cold waves from the Arctic, or from the northwestern prairies. The record high tempei ature, 108° F. (42° C), occurred in Biscotasing on July 20, 1919, in Atikokan on July 11 and 12, 1936, and in Fort Frances on July 13, 1936. The lowest temperature, −73° F. (−58° C), occurred in Iroquois Falls on Jan. 23, 1935.

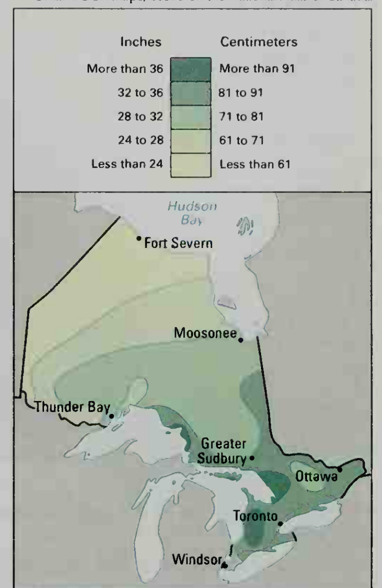
Average January temperatures

Ontario has wide variations in wintertime temperatures. Temperatures moderate steadily from the far north to the south.

Average July temperatures



The southeast and west are the warmest areas in Ontario during the summer. The far north has the coolest temperatures.

Average yearly precipitation

The heaviest amounts of precipitation in the province fall in the southeast. The northeast is the driest section.

WORLD BOOK maps; based on the *National Atlas of Canada.*

The average January temperature in southern Ontario ranges from 12 °F (−11 °C) in Ottawa to 23 °F (−5 °C) in Windsor. The average July temperature is 66 °F (19 °C) in Greater Sudbury and 72 °F (22 °C) in Windsor. The temperature in northern Ontario in January averages −11 °F (−24 °C) at Big Trout Lake and −4 °F (−20 °C) at Moosonee. The temperature in July averages 61 °F (16 °C) at Big Trout Lake and 66 °F (19 °C) at Sioux Lookout.

Ontario's average annual *precipitation* (rain, melted snow, and other moisture) ranges from 24 to 28 inches (60 to 70 centimeters) in the northern part of the province to 31 to 35 inches (80 to 90 centimeters) in the southern part. Annual snowfall in most of Ontario ranges from 48 to 105 inches (123 to 267 centimeters).

Economy

The highly developed industries of Ontario make it one of the richest economic regions of North America. Service industries make up the largest part of the province's *gross domestic product* (GDP)—the total value of goods and services produced in the province in a year. Ontario has a higher GDP than any other province. Ontario leads the provinces in business and high-technology services and in the manufacture of high-technology and industrial products.

The economy of Ontario benefits from the province's location near key North American population centers and waterways. Ontario is close to many large U.S. cities, which provide markets for the province's goods and services. Several major U.S. corporations have large operations in Ontario. The St. Lawrence Seaway provides Ontario's Great Lakes ports with an outlet to the Atlantic Ocean. Thus, ships can travel to and from Ontario ports from any ocean port in the world.

Natural resources. The great forests and abundant wildlife of Ontario are valuable natural resources. Other important resources of the province include fertile soils, many mineral deposits, and a plentiful water supply.

Soil. The soils of the northernmost parts of Ontario are frozen the year around. The Hudson Bay Lowland's soils consist mostly of clay and marshes of moss called *muskeg.* Thin soils cover ancient rock in most of the Canadian Shield. Near the Quebec border, glacial clays and silt cover the fertile clay belts of the Cochrane and Teniskaming districts. The St. Lawrence and Great Lakes lowlands are Ontario's chief farming regions. The St. Lawrence Lowland has black loams and well-drained sands over limestone and shale. The Great Lakes Lowland has rich, sandy soils.

Minerals are found throughout central and northern Ontario in the rocks of the Canadian Shield. The Sudbury Basin, in the southern part of the shield, is the greatest single source of Ontario's mineral wealth. About one-eighth of the world's nickel comes from this district. The ores there also contain cobalt, copper, gold, platinum, and silver. Other areas in the Canadian Shield produce copper, gold, nickel, and zinc. The three Hemlo area mines, on the north shore of Lake Superior, produce over 800,000 troy ounces (25,000 kilograms) of gold annually. The province's other mined products include cement, lime, salt, sand and gravel, and stone.

Service industries, taken together, account for about two-thirds of Ontario's GDP and employ nearly three-fourths of the province's workers. Service industries are

Production and workers by economic activities

Economic activities	Percent of GDP* produced	Employed workers: Number of people	Percent of total
Community, business, & personal services	22	2,176,800	37
Manufacturing	22	1,098,700	19
Finance, insurance, & real estate	21	385,300	6
Wholesale & retail trade	12	874,300	15
Transportation & communication	8	560,300	9
Construction	5	323,600	5
Government	5	274,000	5
Utilities	3	46,400	1
Agriculture	1	97,600	2
Mining†	1	35,200	1
Total	100	5,872,200	100

*GDP = gross domestic product, the total value of goods and services produced in a year.
†Includes figures for fishing and forestry.
Figures are for 2000.

Ontario Ministry of Tourism and Recreation

Farmers harvest grapes from a field in the Niagara fruit belt, a famous fruit-growing region in southeastern Ontario. The province is Canada's leading producer of grapes.

especially important in the major urban areas of southern Ontario.

Community, business, and personal services form the most valuable service industry group in Ontario. This industry sector employs more than a third of the province's workers. Community, business, and personal services include such economic activities as education and health care, professional and scientific services, and the operation of hotels and recreational facilities. Large universities at Hamilton, London, Ottawa, Toronto, and Waterloo employ many people. Many of Canada's largest hospitals, law firms, and hotels are in Toronto. Hotels and many other service establishments benefit from tourist spending. Each year, more tourists visit Ontario than any other Canadian province.

Finance, insurance, and real estate form the second most important service industry group in Ontario in terms of the gross domestic product. Toronto is the nation's leading financial center. Most of Canada's largest banks, insurance companies, and property developers are headquartered there. The Toronto Stock Exchange is one of the largest in North America. Rapid population growth in such metropolitan areas as Kitchener, Oshawa, Ottawa, and Toronto has benefited Ontario's real estate companies by increasing the demand for housing in the province.

Wholesale and retail trade ranks third among Ontario service industry groups in terms of the gross domestic product. The wholesale trade of groceries and of motor vehicles are especially important. Leading types of retail establishments include auto dealerships, department stores, food stores, gas stations, and restaurants.

Transportation and communication rank next among Ontario's service industry groups. Large shipping and trucking companies are based in southern Ontario. Lester B. Pearson International Airport, Canada's busiest air terminal, lies just outside Toronto. Telephone companies are the largest part of the communication industry. More information about transportation and communication can be found later in this section.

Government ranks fifth. Provincial government activities are based in Toronto, and federal government activities are based in Ottawa.

Manufacturing is Ontario's single most important economic activity in terms of the gross domestic product. Goods manufactured in Ontario have a *value added by manufacture* of about 115 billion Canadian dollars yearly. This amount represents the difference between the value of raw materials and the value of finished products made from the raw materials.

About half of Canada's industrial workers live in Ontario. These workers produce about half the country's manufactured products. The Toronto area ranks as Canada's leading industrial center.

The production of transportation equipment is Ontario's chief manufacturing industry. Automobile manufacturing is the main part of this industry. Most of Canada's automobile manufacturing takes place in Ontario. Several major automobile companies have large assembly plants in southern Ontario. Many trucks are also produced in the province. Motor vehicle manufacturing takes place in Alliston, Bramalea, Cambridge, Ingersoll, Oakville, Oshawa, St. Thomas, and Windsor.

Electronic and electrical equipment rank next among Ontario's manufactured products. Telecommunications and computer equipment are the leading types of electronic equipment made in Ontario. Electric appliances are also important. The manufacture of electronic equipment is based mainly in the Toronto and Ottawa areas.

Metal products rank third among the province's manufactures. The leading types of fabricated metal products are structural metal, automobile body parts, and hardware. Steel mills account for most of the primary metal production. Hamilton and Sault Ste. Marie are Ontario's major steel centers.

Food and beverage processing ranks fourth among Ontario's manufacturing activities. Toronto is a major North American meat-packing center. Fruits and vegetables grown in the Great Lakes region of Canada are processed in Ontario factories. Plants in the province produce much milk and other dairy products. Ontario's

Economy of Ontario

This map shows the economic uses of land in Ontario and where the province's leading farm, mineral, and forest products are produced. The major urban areas (shown on the map in red) are Ontario's important manufacturing centers.

mills process Canadian-grown wheat into flour and prepared baking mixes. Beer, soft drinks, and liquor are the leading beverages produced in Ontario.

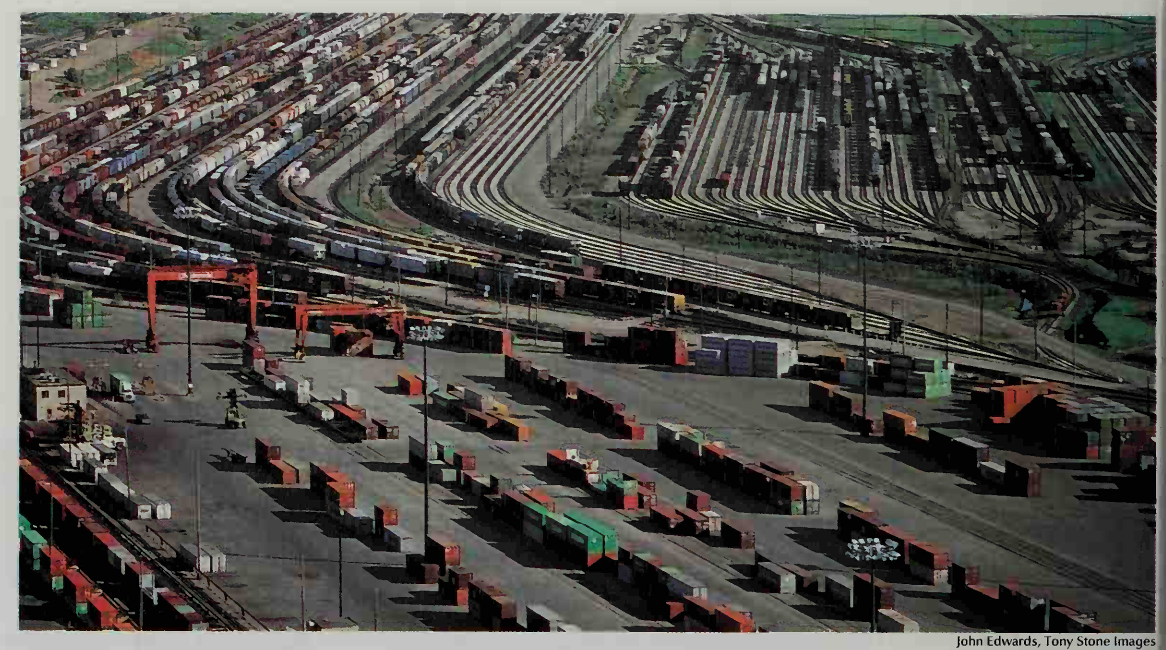
The production of chemicals ranks fifth among Ontario's manufacturing activities. The leading types of chemicals produced in the province are industrial chemicals, pharmaceuticals, and fertilizers.

Other products manufactured in Ontario include machinery, paper products, and printed materials. Construction and mining equipment are the leading types of machinery manufactured in the province. Large paper mills operate in the Niagara Falls area and in Thunder Bay. Print shops and newspaper publishing companies turn out most of the province's printed materials.

Agriculture. Ontario has about 67,000 farms. The farms cover about 14 million acres (6 million hectares)—about 5 percent of the province's land area.

Livestock and livestock products provide about 55 percent of Ontario's farm income. Milk is the leading source of farm income. The raising of beef cattle and hogs rank second and third in importance. Beef and dairy cattle graze on pastureland between the southeastern shores of Lake Huron and the lower western shores of Lake Ontario. Dairying is also important eastward along Lake Ontario and the St. Lawrence River. Farmers in southern Ontario raise large numbers of hogs.

Ontario farmers grow the feed crops they need for their livestock. The major crops include corn, hay, soybeans, and wheat. Ontario leads the provinces in the production of eggs and poultry.



Ontario is also Canada's leading producer of fruits and vegetables. Orchards and vineyards of the famous Niagara fruit belt produce apples, grapes, peaches, strawberries, and other small fruits. The chief vegetables grown in the province include beans, cabbage, carrots, cucumbers, mushrooms, onions, peppers, potatoes, sweet corn, and tomatoes. Tobacco, which grows along Lake Erie, is among the leading cash crops in Ontario.

Ontario also has the largest *floriculture* industry in Canada. Many growers raise flowers and vegetables indoors to protect the plants from the weather and to control the growth of the plants. Greenhouses cover about 2,000 acres (810 hectares) in the province. Many flowers and plants raised in the province's greenhouses are exported to other countries including the United States.

Mining. Most of Ontario's mining income comes from the production of metal ores. The province produces about a third of Canada's metallic minerals.

Gold, nickel, and copper are Ontario's most valuable mineral products. Gold-producing regions are located throughout the Canadian Shield region. The single leading gold-producing area is the Hemlo gold field, which is near Marathon. The Greater Sudbury area is Canada's center of nickel production. Mines in the Greater Sudbury and Timmins areas produce most of Ontario's copper.

Other leading mined products in Ontario include petroleum products, sand and gravel, stone, and zinc. Natural gas and petroleum have been found in southern Ontario and beneath the waters of Lake Erie. Sand and gravel are obtained primarily from pits in the southeastern part of the province. Granite, limestone, and marble

Freight containers, carried piggyback on railroad flatcars, await shipment at a sprawling rail yard outside Toronto. Ontario has about 7,800 miles (12,500 kilometers) of railways, about a fourth of Canada's total. Southern Ontario has the finest railway network in Canada.

from Ontario grace buildings around the world. Zinc is mined in the Timmins area. Other mined products found in Ontario include cement, clay, cobalt, gypsum, lime, magnesium, platinum, salt, and silver.

Electric power and utilities. Nuclear power plants produce about half of Ontario's electric power. Hydroelectric plants supply about a fourth. Fuel-burning plants also produce about a fourth. Ontario has about 70 hydroelectric plants, 6 fuel-burning electric stations, and about 10 nuclear power plants. Ontario and the state of New York share the water of Niagara Falls under terms of a 1910 treaty between Canada and the United States. Other utility companies provide the province's people with gas and water service.

Transportation. Waterways have played an important part in the history of Ontario. French explorers traveled up the Ottawa River in canoes. Early canals, particularly the Rideau and Trent systems, carried passengers and freight. The St. Lawrence Seaway, which was completed in 1959, brought oceangoing ships to the inland ports (see **Saint Lawrence Seaway**).

During the navigation season, from late March or early April to late December, many freighters travel between the ports of Ontario and those of the United States. Grain-carrying ships crowd the docks of Thunder Bay on Lake Superior. Ontario has 540 miles (869 kilometers) of canals, with over 100 locks. The Trent Canal is a recreational canal which extends 240 miles (386 kilometers) between Trenton and Georgian Bay.

Lester B. Pearson International Airport, just outside Toronto, is the largest and busiest airport in Canada. A number of government, industrial, and private airlines carry passengers and supplies to distant mining and lumbering camps in the northern part of Ontario.

Ontario has about 7,800 miles (12,500 kilometers) of railways, about a fourth of Canada's total. Southern Ontario has Canada's finest railway network. Toronto is the province's chief rail center. The Canadian National Railway, the Canadian Pacific Railway, and VIA Rail are the largest railways in Ontario. The province owns the Ontario Northland Railway, whose main line runs through the clay belt and the silver-mining region to James Bay. A government-owned rail and bus system serves over 100,000 commuters in Toronto each weekday.

About 13,400 miles (21,600 kilometers) of highways crisscross the province. Nearly all of these highways are paved. Part of the east-west Trans-Canada Highway runs across Ontario. A 510-mile (821-kilometer) expressway stretches from Windsor to the Quebec border.

Communication. Louis Roy, a Frenchman from Quebec, published the first newspaper of the Ontario region. His paper, the *Upper Canada Gazette, or American Oracle,* first appeared in 1793 in Newark (now Niagara-on-the-Lake). York (now Toronto) became the capital of Ontario in 1797, and the *Gazette* moved there in 1798. It was published until 1849.

Today, over 450 newspapers are published in Ontario, including about 45 dailies. *The Toronto Star* ranks first in circulation. Ontario's other leading dailies include *The Globe and Mail* and the *National Post* of Toronto, *The Toronto Sun, The Ottawa Citizen, Le Droit* of Ottawa, *The* (Hamilton) *Spectator, The London Free Press, The Mississauga News,* and *The Windsor Star.* About 700 magazines are published in Ontario.

Ontario's first radio station, CKOC, began broadcasting in Hamilton in 1922. The first TV station, CBLT, was founded in Toronto in 1952. Today, Ontario has about 170 radio stations and 20 TV stations. Cable television systems and Internet providers serve many Ontario communities.

Lieutenant governor of Ontario represents the British monarch, Queen Elizabeth II, in her role as the queen of Canada. The lieutenant governor is appointed by the governor general in council of Canada. The position of lieutenant governor is largely honorary.

Premier is the actual head of government. Ontario, like the other provinces and Canada itself, has a parliamentary government. The premier is an elected member of the Legislative Assembly and is usually leader of the Assembly's majority party. The head of Ontario's government was called the premier until 1906, when the title was changed to prime minister. In 1972, Prime Minister William Davis changed the title back to premier.

The premier presides over the Executive Council (cabinet). The Executive Council includes ministers chosen by the premier from members of the premier's party in the Assembly. Each minister directs a government ministry, except a small number who are called *associate ministers.* The Executive Council, like the premier, resigns if it loses the support of a majority of the Assembly.

Legislative Assembly is a one-house legislature that makes the provincial laws. It has 103 members who are elected from 103 electoral districts called *constituencies.* Their terms may last up to five years. However, the lieutenant governor, on the advice of the premier, may call for an election before the end of the five-year period. All members may run again for office.

Courts. Ontario's highest court is the Court of Appeal. It consists of a chief justice, an associate chief justice, and 16 other justices.

The rest of the court system, called the Ontario Court of Justice, is divided into the General Division and the Provincial Division. The General Division hears major civil, family, and criminal cases. It has a chief justice, an associate chief justice, regional senior judges, and about 200 other judges. This division also contains the Divisional Court, the Family Court, and the Small Claims Court. The Divisional Court hears reviews of provincial administrative action and some General Division appeals. The Family Court hears all aspects of family law disputes. The Small Claims Court hears minor civil cases. General Division justices are appointed by Canada's governor general in council and serve until age 75.

The Provincial Division handles provincial offenses and some family and young offenders cases. The Provincial Division has a chief judge, 2 associate chief judges, regional senior judges, and over 250 other judges. The judges are appointed by the provincial lieutenant governor in council and serve until age 65.

Local government. Ontario has three basic municipal units: upper-tier municipalities (regions, counties, and the District of Muskoka); lower-tier municipalities (cities, towns, villages, and townships); and single-tier municipalities (areas where there is only one level of municipal government).

Since 1996, the province's municipal structure has undergone considerable change. The number of munici-

The premiers of Ontario*

	Party	Term
John S. Macdonald	Liberal	1867-1871
Edward Blake	Liberal	1871-1872
Oliver Mowat	Liberal	1872-1896

The Legislative Assembly meets in the main Provincial Parliament Building in Toronto. Each of the Assembly's 103 members serves a term of up to five years.

palities in Ontario has been reduced from 815 to 447. The number of regional municipalities has been reduced from 13 to 8, and the single-tier municipalities of Toronto, Greater Sudbury, Hamilton, Ottawa, Haldimand County, and Norfolk County have been created. Outside the major cities, many lower-tier municipalities have been *amalgamated* (combined) within existing counties. In some cases, this amalgamation has resulted in the transformation of entire counties into new single-tier municipalities. Despite the amalgamations, about half of Ontario's municipalities still have populations of less than 5,000, and much of northern Ontario remains sparsely settled with no municipal organization.

Municipalities provide many local and regional services. In southern Ontario, counties, regional municipalities, and cities have been designated to provide a range of social services and housing. In the northern part of the province, district boards provide health and social services to municipalities and to areas without municipal organization.

Revenue. Taxes collected by the provincial government provide about three-fourths of the province's *general revenue* (income). Most of this money comes from taxes on personal and corporate income, retail sales, payroll, and gasoline sales.

Politics. The province has three major political parties. They are the Progressive Conservative, Liberal, and New Democratic parties. The Progressive Conservative Party was formerly named the Conservative Party, and today its members are usually called simply Conservatives.

Ontario's first provincial government was a *coalition* (combination) of Liberals and Conservatives. The Liberals took full control of the government in 1871 and held it until 1905, when the Conservatives came to power. In 1919, during an economic depression, the United Farmers of Ontario took over the government. The Conservatives regained leadership in 1923 after the economy improved, but they lost it to the Liberals in 1934.

The Progressive Conservatives won control of the government in 1943. They held power until 1985, when the Liberals assumed control. The New Democratic Party gained control of the government in 1990. In 1995, the Progressive Conservatives again won power. Ontario citizens must be at least 18 years of age to vote in federal or provincial elections.

History

Indian days. Three major Indian groups lived in what is now Ontario when white explorers first arrived. Chippewa Indians hunted beavers and small game in the forests north and east of Lake Superior. Huron Indians lived between Lake Huron and Lake Ontario. They depended mainly on cultivated crops for food. The Chippewa and Huron feared wandering bands of Iroquois Indians, who sometimes raided their camps.

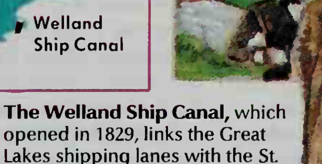
Exploration. The first white person to explore the Ontario region was Étienne Brulé of France. He was sent in 1610 by Samuel de Champlain, the founder of Quebec. In 1613, Champlain paddled up the Ottawa River. He journeyed farther south in 1615, into the Lake Huron area. Champlain found this region rich in fur-bearing animals. Young French fur traders followed his course to collect pelts. They traveled deep into the forests, and traded beads and knives to the Indians for furs. In the 1620's and 1630's, other French explorers, including Brulé and Jean Nicolet, traveled farther than Champlain. They explored the Lake Superior region, Lake Michigan, and beyond. See **Champlain, Samuel de**.

Early settlement. French missionaries followed the fur traders into the Ontario region. In 1639, Jesuit priests built Fort Sainte Marie as the center of a group of missions. These missions, known as Huronia, were established among the Huron Indians. The Iroquois Indians forced the Jesuits to abandon the missions in 1648 and 1649. During the 1650's and 1660's, French explorers entered the region north of Lake Superior. These explorers included Pierre Esprit Radisson and Médard Chouart, Sieur des Groseilliers. Their explorations led to the founding of the Hudson's Bay Company in London (see **Hudson's Bay Company**).

In 1763, at the end of the French and Indian War, France gave the Ontario region to Britain. By then, there were only a few scattered French settlements near what are now Kingston, Niagara Falls, and Windsor. Little further settlement took place until 1784. That year, after the Revolutionary War in America, people loyal to England began arriving from the United States. About 6,000 of these United Empire Loyalists, as they were called, had arrived by 1785. They settled west of the Ottawa River. The Loyalists had lost their homes and wealth. The British government gave them food, clothing, land, livestock, and seed. About 4,000 other settlers also arrived from the United States. See **United Empire Loyalists**.

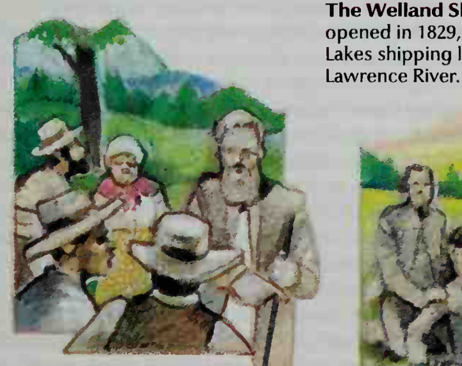
Upper Canada. In 1791, the southern part of what is now Ontario became the separate colony of Upper Canada. Newark (now Niagara-on-the-Lake) was the capital. The British government appointed a lieutenant governor to govern the colony. The lieutenant governor appointed a 7-member legislative council, and the people elected a 16-member legislative assembly. Colonel John Graves Simcoe, the first lieutenant governor, promoted roadbuilding and expanded settlement. In 1793, Simcoe chose York (now Toronto) as the site for a new capital, and the government completed moving there in 1797.

Gradually, more settlers arrived, some in organized groups. Others were brought by land-development firms, such as the Canada Company. These settlers were assigned farms on land owned by the companies. Many Americans who liked frontier life or wanted more land also came. Sometimes whole communities moved north. A group of Pennsylvania Dutch, for example, settled near what is now Kitchener. Traders from the Hudson's Bay Company posts in the far north settled with their families in the southern towns. Most of these people were Scottish or English.

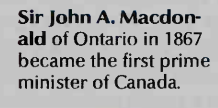


The War of 1812 between Britain and the United States began 21 years after Upper Canada was created. More than half the people of the colony were former Americans. However, most of them were loyal to their new homeland. British and Canadian troops halted invading United States forces in several battles in Upper

Historic Ontario



Étienne Brulé of France was the first white person to explore the Ontario region. He was sent in 1610 by Samuel de Champlain, the founder of Quebec.



The Welland Ship Canal, which opened in 1829, links the Great Lakes shipping lanes with the St. Lawrence River.

Thousands of slaves fled from the United States to Ontario in the 1850's. Antislavery leader John Brown had many followers around Chatham.

A rebellion in 1837 was led by William Lyon Mackenzie, a former member of the Legislative Assembly. A colonial militia put down the uprising. Several rebels were executed or imprisoned.

Sir John A. Macdonald of Ontario in 1867 became the first prime minister of Canada.

Important dates in Ontario

1610 Étienne Brulé of France became the first white person to explore the Ontario region.

1613 Samuel de Champlain of France explored the Ottawa River area.

1639 French missionaries founded Fort Sainte Marie.

1648-1649 Indians destroyed the French missions.

1763 The Ontario region became a British possession.

1791 The region became the province of Upper Canada.

1812-1814 American forces invaded Upper Canada during the War of 1812.

1837 A rebellion against British rule broke out in Upper Canada.

1867 Ontario became one of the original four provinces of the Dominion of Canada on July 1.

1883 The world's largest copper-nickel reserves were discovered at Sudbury (now part of Greater Sudbury).

1904 Ontario's automobile industry began in Windsor.

1912 Ontario gained the territory north of the Albany River.

1952 The Western world's largest uranium deposit was discovered at Elliot Lake.

1959 The St. Lawrence Seaway opened.

1964 A huge field of copper, silver, and zinc was discovered near Timmins.

1972 Ontario began a program of free medical and hospital care for the elderly and the poor.

1982 Large gold deposits were discovered at Hemlo, near Marathon.

1985 Liberals, supported by New Democrats, gained control of the government, after 42 years of Progressive Conservative rule.

1990 The New Democratic Party gained control of the government.

1995 The Progressive Conservatives regained control of the government.

Canada. See War of 1812 (Chief battles of the war).

Early industrial growth. The population of Upper Canada grew rapidly during the 1820's. Towns such as Bytown (now Ottawa) became thriving centers of trade. Canals, mills and small factories, and roads were built. The Rideau, Trent, and first Welland canals date from this period. In 1825, the Erie Canal linked Lakes Erie and Ontario with New York City. Large groups of immigrants, most of them from Ireland, came after these transportation improvements were made.

Political unrest. During the 1830's, Upper Canadians became greatly dissatisfied with their government. They elected only the Legislative Assembly. The real power lay with the lieutenant governor, who was appointed by the British government. The lieutenant governor appointed the Legislative Council and the Cabinet. The Legislative Council generally represented the wealthy and powerful persons of the colony. The council often blocked legislation that the people wanted and the assembly had passed. This legislation included building new roads and schools, and providing free land to settlers.

Both the colonial and British governments ignored demands for political reform. William Lyon Mackenzie, a member of the Legislative Assembly, and a small group of followers rebelled in 1837. A colonial militia put down the uprising. Several rebels were executed, some were imprisoned, and others, including Mackenzie, fled to the United States. See **Rebellions of 1837**.

In 1840, the British Parliament passed the Act of Union. This act, which took effect in 1841, united Upper Canada and Lower Canada (part of present-day Quebec) into a single colony called the Province of Canada. In 1848, the colony gained *responsible government.* Under responsible government, a Cabinet is chosen from a party or group that can command the support of a majority in the elected assembly. The governor acts on the advice of the Cabinet in local matters.

Confederation. In 1864, politicians from the Province of Canada proposed a federal union of all the British colonies in eastern North America. All except Prince Edward Island and Newfoundland agreed to join the confederation. On July 1, 1867, the British North America Act created the Dominion of Canada. New Brunswick, Nova Scotia, Ontario, and Quebec became provinces in the Dominion. Ottawa was made the federal capital, and Sir John A. Macdonald of Ontario became the first prime minister of Canada. John S. Macdonald, unrelated to him, was the first premier of Ontario. See **British North America Act**.

Progress as a province. Ontario's economy grew slowly during the depression that followed confederation. Farming increased with the development of scientific methods and the use of machinery. Lumbering expanded in the Canadian Shield. During the 1880's, construction of the Canadian Pacific Railway and extension of canals helped attract settlers to western Ontario. Manufacturing increased, but many Ontarians moved to the United States for better job opportunities. In 1883, the world's richest copper-nickel deposits were found near Sudbury (now part of Greater Sudbury). Major mining did not begin until after 1892, when a practical process for separating copper and nickel was developed.

The early 1900's. The long depression ended in 1897, and manufacturing began to increase rapidly. Cobalt became a thriving mining center after a huge silver deposit was discovered near the city in 1903. Extensive mineral exploration took place throughout the Canadian Shield. Within a few years, many new deposits of gold, silver, and other minerals were discovered. The region became one of the world's richest mining areas.

A pulp and paper industry developed in Ontario during the early 1900's, and it soon grew to major importance. Ontario's automobile industry began in 1904, when ferryboats first carried automobile parts across the Detroit River from Detroit, Michigan, to Windsor. Windsor became an automobile assembly center. In 1906, the provincial government established the Hydro-Electric Power Commission of Ontario. This agency developed Niagara Falls and other hydroelectric sources.

In 1912, Ontario's northern boundary was extended from north of the Albany River to Hudson and James bays. This action gave the province its present area. The outbreak of World War I (1914-1918) hastened Ontario's economic growth. Ontario led the provinces in the production of weapons and other military supplies.

During the 1920's, after a short depression, old cities became larger and new ones grew in number. Prospectors developed new mines in the northern forest regions. Many Finns, Scandinavians, and French-speaking Canadians from Quebec settled in these regions. Automobile production continued to grow. The iron and steel and the pulp and paper industries prospered. The prosperity ended with the Great Depression of the 1930's. During the 1930's, many Jewish families escaped Nazi persecution in Germany and came to Ontario.

The mid-1900's. During World War II (1939-1945), Ontario's factories, farms, and mines increased production to help arm and feed the Allied armies. Later, hundreds of thousands of Europeans left their war-torn countries and came to live in Ontario. More than half of the 3 million people who settled in Canada between 1945 and 1970 made their homes in Ontario. Ontario's population rose from about 4 million to 7 $\frac{1}{2}$ million.

In 1945, Canada's first nuclear reactor went into operation near Chalk River. Laboratories there worked to find ways to develop cheap nuclear power for Ontario's expanding industries. By 1960, the station had five experimental reactors and other research facilities, including a particle accelerator.

Ontario experienced its greatest economic growth after World War II (1939-1945). By the early 1950's, Ontario's manufacturing production had doubled. Discoveries of various minerals contributed to the economic boom. In 1952, one of the world's largest single uranium ore deposits was found at Elliot Lake. In 1953, prospectors found another huge uranium deposit near Bancroft and a rich zinc-copper field at Lake Manitouwadge.

Also during the 1950's, pipelines were laid to carry natural gas and oil to Ontario from western Canada. The oil, piped to Sarnia, led to the development of that city's great refining industry. Ontario's iron and steel industry grew rapidly. Ontario also expanded hydroelectric stations at Niagara Falls and other sites.

Ontario's economic growth continued during the 1960's. Factory production again doubled. The province's growing industries required great increases in

electric power. Ontario began to make use of nuclear power research conducted at the Chalk River reactor. Canada's first nuclear power station, at Rolphton, began operating in 1962. Its success led to the development of the nation's first full-scale nuclear station, which began operating at Douglas Point in 1967. A nuclear plant at Pickering began operations in 1971.

Many other research programs were started to promote Ontario's industrial growth. In 1966, the Sheridan Park Research Community, consisting of several private industries, set up the first of its multimillion dollar facilities near Toronto. In 1964, a huge field of copper, silver, and zinc ores was discovered near Timmins. An open-pit mine began operating there in 1966.

In 1965, Canada and the United States signed a pact on car manufacturing. Under this agreement, Canadian and U.S. companies would produce different automobile lines for sale in each of the two countries.

The 1970's and 1980's. Ontario's strong economic growth helped Toronto to emerge as Canada's leading financial center in the 1960's and 1970's. Most banks and many other financial institutions and Canada's major stock exchange have their headquarters in Toronto.

Tourism became increasingly important to Ontario's economy. The province's woods and lakes have drawn growing numbers of vacationers. Historic sections of Toronto and other Ontario cities also attract visitors.

In 1972, Ontario began to provide free medical and hospital care for people aged 65 and older and for the poor. During the 1970's and 1980's, Canada suffered an economic recession. But because of the diversity of Ontario's economy, the province was hurt less and recovered more rapidly than did most provinces of Canada.

In 1982, large gold deposits were discovered at Hemlo, near Marathon. Mining of gold ore began in 1985.

Recent developments. In 1994, the North American Free Trade Agreement (NAFTA) went into effect. The pact created a regional trading bloc between Canada, Mexico, and the United States. It was built on a free-trade agreement between the United States and Canada that became effective in 1989. NAFTA calls for the gradual elimination of tariffs and other trade barriers.

The free trade agreements removed government restrictions against U.S. imports, thus creating greater competition for Ontario manufacturers. Provincial officials are focusing efforts on ensuring that, under free trade, American companies with Ontario branches do not begin to import goods rather than continuing to produce them within Ontario. Many Ontarians would lose their jobs if these U.S. branches ceased operations.

The province faced a growing budget deficit during the 1980's and early 1990's. In provincial elections held in 1995, the Progressive Conservatives won a large majority of seats in the Ontario legislature, and Michael D. Harris became premier. In an effort to reduce the deficit, Harris introduced a wide range of cuts in spending on government programs. For example, he reduced funding for welfare, cities, health care, and education. In addition, as part of his strategy to produce jobs, he cut the province's income tax rate. Although Harris's economic program created a large amount of controversy, the Conservatives again won a majority of seats in the Ontario legislature in elections held in 1999. In March 2002, the Conservatives elected Ernie Eves to replace Harris.

In 1997, Ontario's legislature voted to merge the members of the Municipality of Toronto into a single city of Toronto. The merger took effect in 1998. In 1999, the legislature enacted another municipal merger law that affected a number of Ontario communities. For example, the cities of Ottawa, Hamilton, and Sudbury were merged with surrounding communities and rural areas to form enlarged cities. These mergers took effect at the beginning of 2001. Onyx, *AHN ihks,* is a term used loosely to apply to a banded carbonate rock and also to agate, a fine-grained variety of quartz (see **Agate**).

Ordinary onyx of quartz is black and white, green and white, or red and white, and so on. *Sardonyx* is a reddish-brown and white onyx. Onyx is hard and takes a high polish. It is widely used in the carving of cameos and intaglios. Today, jewelers refer to single-color agate as *onyx.* When they speak simply of onyx, they mean the black stone.

Onyx marble (*Mexican onyx*) is a variety of calcite rock found on the walls of caves. Mexican onyx shows a banding like that of agate, but it is much coarser. The colors of Mexican onyx range from white to green, red, and brown. Much of this soft onyx marble is cut into gemstones, colored with an aniline dye, then set in inexpensive native silver jewelry. The stones are brittle and not durable. Mexican onyx is also used as a decorative stone. John C. Butler

Oort cloud, *oort* or *ohrt,* is a cluster of comets, smaller objects, and perhaps even planets in the outermost region of our solar system. The Oort cloud is shaped like a slightly flattened, hollow sphere. The nearest part of the cloud is roughly 500 billion miles (800 billion kilometers) from the sun. The farthest part may be 5 trillion miles (8 trillion kilometers) from the sun. The cloud holds up to 1 trillion comets. A comet can leave the Oort cloud and enter the inner solar system when disturbed by a large gravitational force, such as the gravity of a passing star.

The Oort cloud is named for the Dutch astronomer Jan H. Oort, who in 1950 suggested that it existed. Oort based his suggestion on two characteristics of the orbits of *long-period comets*—those that take 200 years or longer to revolve once around the sun: (1) The orbits originate hundreds of billions of miles or kilometers from the sun, and (2) The orbits intersect the *ecliptic plane* at random angles. The ecliptic plane is an imaginary surface through Earth's orbit around the sun. If long-period comets intersected the plane at small angles—as do short-period comets, which complete their orbits in less than 200 years—the cloud would be disk-shaped. Short-period comets come from the Kuiper belt, a disk-shaped band of rocky objects orbiting the sun just beyond Neptune. S. Alan Stern

Oostende. See **Ostend.**

Ooze is a name for the deposits found on the bottom of the ocean in deep waters. One type of ooze consists of a reddish-brown mud called *red clay.* The other major type of ooze is made up mostly of skeletons and shells of tiny sea organisms called *foraminifera, radiolaria,* and *diatoms.* All three are termed *plankton,* which is the name for forms of life that float in the water and drift with currents. The foraminifera make their shells from calcium carbonate that is contained in solution in the seawater. A type of limestone called *nummulitic limestone* is made up mostly of the discarded shells. The skeletons of the radiolaria and diatoms are usually composed of silicon.

The term *ooze* is also used for any mud that has a high water content. Such mud may be deposited either on the surface of the earth, or in the beds of rivers, streams, ponds, or lakes. J. M. Coleman

Opal, *OH puhl,* is a gemstone that contains a rainbow of colors. It is made up of silicon and oxygen, the elements found in common sand. The background colors of an opal may be black, blue, brown, gray, or white. Opals show brilliant colors when turned in a bright light.

The most prized opals are called *black* opals. These opals have a black, blue, or gray background. High quality black opals are found in New South Wales, Australia. These opals are highlighted by brilliant flashes of reds and golds in addition to flashes of greens and blues.

Opals are unique among gemstones because of their unusual internal structure. This structure consists of numerous tiny spheres of silica that are packed together in a regular pattern to form layers. The *refraction* (bending of light between these layers causes the light to break up into the colors of the rainbow, thus producing the

gemstone's extraordinary flashes of color. Opals may be found in irregular patches, often filling cavities and cracks in rocks.

In some opals, the water dries up and the opal becomes covered with tiny cracks. This process is called *crazing,* and it detracts from the value of the stone. Opals also are not as hard as most gems, and they may easily be scratched or chipped.

There are many different kinds of opals. Opals that display brilliant color flashes are *precious* opals. Most precious opals are mined in Australia. Mexico is known for its *water* opals and *fire* opals. Water opals are colorless and transparent and give off bright flashes of color. Fire opals are orange or red, and most do not give off color flashes. Opals that do not show color flashes are called *common opals* and are usually not considered gem material.

Because the beauty of opals lies in their internal color flashes, they are rarely cut with facets as diamonds are. Instead, they are cut with a gently rounded surface. This style of cutting is called *cabochon* cutting.

Gemological Institute of America

White opal

Large opals of the world include a Hungarian opal that weighs 594 grams, now in the Museum of Natural History in Vienna. The *Roebling* opal, which was found in Nevada, is the most beautiful American opal. It is almost pitch-black, with color flashes of great brilliancy. It weighs 530 grams and is on display at the National Museum of Natural History in Washington, D.C. The huge *Desert Flame of Andamooka* opal weighed over 6,800 grams when found in Australia in 1969. The opal is one of the birthstones for October. Robert I. Gait

Oparin, Alexander Ivanovich (1894-1980), was a Soviet biochemist. His theory of how life on earth originated from chemical substances became the basis of many later scientific ideas about the origin of life. Oparin also conducted research on the chemical conversion of raw agricultural crops into such products as bread, sugar, and wine.

Oparin's theory of the origin of life rests on his assumption that the mixture of gases in the earth's early atmosphere was much different from that of today's atmosphere. The present atmosphere is about 99 percent oxygen and nitrogen. In Oparin's view, the early atmosphere was mostly ammonia, hydrogen, and methane. These gases are composed of simple molecules.

Large amounts of these gases would have dissolved in the oceans and would have received energy from sunlight, lightning, and the earth's internal heat. Oparin suggested how this energy could have caused the simple molecules to combine into more complex molecules and how the complex molecules could have formed larger and larger combinations. After several hundred million years, such combinations could have formed the first living cells.

Oparin was born near Moscow. He graduated from Moscow State University in 1917. He first published his theory in 1924 and expanded it into a book called *The Origin of Life on Earth* (1936). From 1946 to 1980, Oparin headed the Bahk Institute of Biochemistry in Moscow.

Open-Door Policy is a term used in international relations. It means that powerful countries have equal opportunities to trade with colonial or developing countries. When countries agree to observe the Open-Door Policy in an area, they simply agree to permit their merchants and investors to trade freely there.

John Hay, United States secretary of state, started the idea of the Open Door in 1899. At that time, several Western powers had special interests in China. Each power was trying to get all the trading rights for itself. Hay sent notes to the competing powers, asking them to maintain complete equality for all nations that wished to trade with China. The competing powers accepted Hay's proposal, and they signed treaties agreeing to observe the Open-Door Policy. Robert J. Pranger

Open housing refers to the belief that people have a right to live wherever they choose and can afford to live. The United States government and many local and state governments have passed laws and regulations to protect this right. The laws prohibit discrimination in the sale and rental of housing on the basis of race, religion, disability, family status, or nationality. Open housing laws are sometimes called *fair housing* laws or *open occupancy* laws.

The U.S. Civil Rights Act of 1968 included the first national open housing legislation of the 1900's. The act prohibits discrimination in the sale or rental of most of the housing in the United States. It applies to all housing except (1) owner-occupied dwellings of four or fewer units, such as boarding houses; and (2) single-family houses sold or rented without the aid of a broker or real estate agent.

In June 1968, the Supreme Court of the United States went beyond the 1968 act. It ruled that a federal law passed in 1866 prohibits discrimination in the sale and rental of all property. In 1988, Congress passed a law that protected disabled people and families with children from discrimination in the sale and rental of housing. However, the fair housing laws are weakly enforced in the United States, and discrimination against African Americans and other minority groups in the housing marketplace is still common. Joe R. Feagin

Scene from a production by the Royal Opera, Covent Garden, London; Reg Wilson

Elaborate scenery and colorful crowd scenes add excitement to many operas. The spectacular "Triumphal March" shown above takes place in Act II of Giuseppe Verdi's tragic opera *Aida*.

Opera

Opera is a drama in which the characters sing, rather than speak, all or most of their lines. Opera is one of the more complex of all art forms. It combines acting, singing, orchestral music, costumes, scenery, and often ballet or some other form of dance.

In telling a story, opera uses the enormous power of music to communicate feeling and to express emotions. Singers, accompanied by an orchestra, may bring a dramatic situation to life more vividly than actors with spoken dialogue. Vocal and orchestral music can also tell an audience much about a character and his or her state of mind.

Because music expresses emotions so forcefully, most opera composers base their works on highly emotional stories. An opera, more than a spoken play, is likely to emphasize passionate scenes of anger, cruelty, jealousy, joy, love, revenge, sadness, or triumph. Music can also add excitement to scenes portraying spectacle. Some of the most stirring music in opera accompanies colorful crowd scenes, such as a coronation or a military parade.

Opera differs in several ways from other kinds of plays that have music. For example, William Shakespeare's comedy *A Midsummer Night's Dream* has scenes that call for music. Such music is called *incidental music* because the play is dramatically complete without it. Different productions of the same play may use incidental music by different composers.

Musical comedies and operettas resemble opera, but most of them have much more dialogue than an opera has, and their music is lighter. Compositions called *oratorios* also share certain features with opera. Like an opera, an oratorio has music for soloists, chorus, and orchestra. It may also tell a story. But unlike operas, almost all oratorios are performed in a concert hall and without acting, costumes, or scenery.

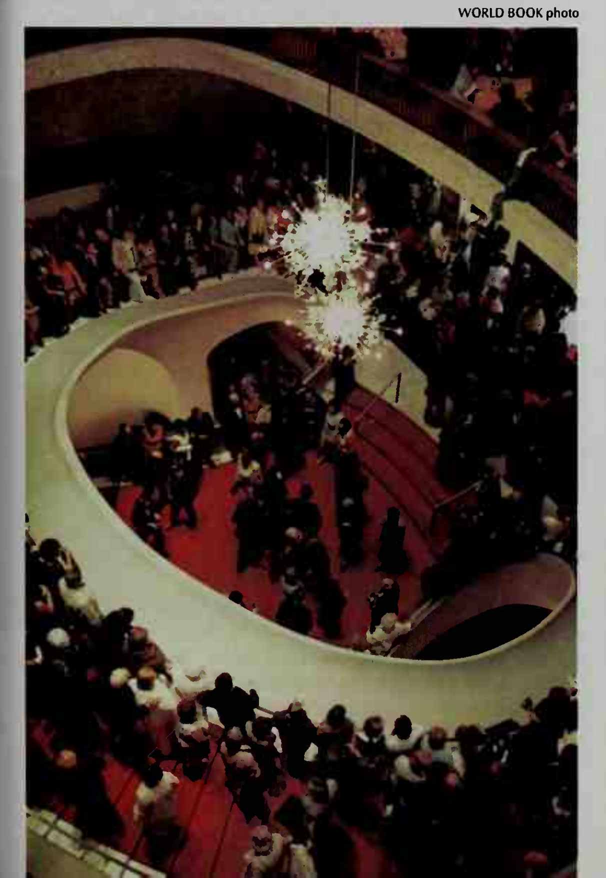
Organizations called opera companies produce most operas. Most companies are *repertory theaters*—that is, they present several operas alternately during a season. The operas a company presents are called its *repertoire*.

Operas are usually performed in specially designed theaters called *opera houses*. Most opera houses seat many more people than do theaters reserved for spoken drama. An opera house also has special facilities and equipment to provide the elaborate staging required by many operas. All modern opera houses have an orchestra pit between the stage and the seats of the auditorium. From the pit, the orchestra, led by the conductor, accompanies the singers onstage.

Most opera houses built in the 1700's and 1800's, and

Thomas A. Bauman, the contributor of this article, is Professor of Music at Northwestern University.

some modern ones, have rows of boxes arranged in the auditorium. Originally, the boxes were owned by the nobility who patronized the opera and were occupied by their families and guests. Because it is difficult to get a good view of the stage from many box seats, modern opera houses rarely feature this arrangement.



Opera, as we know it today, began in Italy in the late 1500's. Through the years, Italian composers, singers, and conductors have played a leading role in the development of opera. By the end of the 1600's, opera had spread from Italy to other European countries. Today, opera can be enjoyed in many parts of the world.

The best-known companies in Europe include those that perform at the Teatro alla Scala (La Scala) in Milan, Italy; the Opera House in Rome; the Opéra de la Bastille and the Opéra-Comique in Paris; the Royal Opera House, Covent Garden, in London; the State Opera in Vienna; and the Festival Opera House in Bayreuth, Germany.

The most famous opera company in the United States is the Metropolitan Opera Association, which performs in New York City. The Boston Opera Company, the Lyric Opera of Chicago, the New York City Opera, and the San Francisco Opera Company are also famous. Other important American companies include the Greater Miami Opera, the Houston Grand Opera, the Seattle Opera, the San Diego Opera, and the Washington (D.C.) Opera. Every summer, the Santa Fe Opera Company performs in an outdoor theater in Santa Fe, N.M.

Opening night at the opera ranks as one of the most glamorous social events of the year. The opening-night crowd below mingles in the lobby of the Metropolitan Opera House.

WORLD BOOK photo

Terms used in opera

Aria, *AH ree uh,* is a vocal solo that usually expresses a character's feelings.
Bel canto refers to a style of singing that emphasizes beautiful tone and technical skill.
Coloratura is a flowery, ornamental vocal style generally used by soprano voices.
Ensemble, *ahn SAHM buhl,* is a small group of singers, usually from two to five. The music the group sings is also called an *ensemble.*
Grand opera refers to operas of the mid-1800's that emphasized spectacular stage effects, big crowd scenes, and complicated, elaborate vocal and instrumental music. The term *grand opera* also means an opera with no spoken dialogue.
Leitmotif, *LIHT moh TEEF,* is a short musical passage that identifies certain ideas, places, and characters each time they appear in the drama.
Libretto is the text of an opera.
Opera buffa, *BOOF fah,* is an Italian comic opera that deals with humorous situations and characters from everyday life.
Opera seria, *SEH ree ah,* was the leading opera form of the 1700's. It dealt primarily with historical themes from ancient times and stressed brilliant singing.
Recitative, *REHS uh tuh TEEV,* is a part of the text that provides information about the action and moves the plot forward. It is sung in a rapid, speechlike style, sometimes to orchestral accompaniment. In *simple recitative,* the accompaniment is provided by only a harpsichord or a harpsichord and cello or other bass instrument.
Score is the written or printed music for an opera, used by the conductor.
Singspiel, *ZIHNG shpeel,* is a form of German opera, usually comic, that has spoken dialogue instead of recitative. Most of the songs are simple and folklike.
Verismo, *vair EEHS moh,* is a style of realistic Italian opera that focuses on violent actions and emotions.

The elements of opera

An opera has two basic elements: (1) the libretto and (2) the music. The libretto, which means *little book* in Italian, consists of the words, or text, of an opera. The music, which is also called the *score,* consists of both vocal and instrumental music. To translate the libretto and music into a performance, an opera must have singers, a conductor, and an orchestra.

The libretto

To enjoy an opera fully, an operagoer should read the libretto or a summary of the action beforehand. It is especially important to read a translation of the libretto or a summary if an opera is sung in an unfamiliar language. Some public libraries have librettos. Most of them have books that contain summaries of the action in individual operas. Generally, an opera house provides a program that has a summary of the plot. Most American opera houses provide translations on a screen above the stage.

The libretto of most operas is shorter than the text of a spoken play because it takes longer to sing a given number of words than to speak them. Librettos may also be shorter than the script of a spoken play because a few measures of music can often express emotions more vividly than many lines of spoken dialogue can. Because a libretto has to be relatively short, the story of an opera is likely to be simpler than that of a spoken

play, with fewer characters and fewer secondary plots.

Many operas have been criticized for their poor librettos. Such operas give the impression that the composer used the text merely as an excuse for the music. Many people do attend the opera mainly to hear beautiful music sung by beautiful voices. Other people, however, feel that a good opera must also be a good drama. And in fact, some librettos are excellent works of literature. These librettos include those that the Austrian poet Hugo von Hofmannsthal wrote for the operas of Richard Strauss.

The definition of good drama in opera has changed over the years. Numerous subjects that were popular in operas of the 1600's, 1700's, or 1800's are now out of fashion. Yet modern operagoers can still enjoy these older operas if they learn something about the customs in drama and music that influenced their composition.

Recitative and arias. Certain parts of the libretto simply provide information for the audience. For example, one character may tell another about something that has happened. In some operas, including nearly all Italian operas, the characters speak these portions of the text. But in many operas, the characters sing them in a simple, speechlike style called *recitative.* Most recitatives are written in everyday language—that is, they do not rhyme. Recitatives were especially popular in operas of the 1700's and early 1800's.

The most emotional parts of the libretto are solo numbers called *arias.* They usually express a character's feelings or thoughts. Most arias are written in rhythmical, rhymed verse. They are also set to far more elaborate music than are recitatives. In fact, arias provide the most beautiful and dramatic music in many operas.

Spoken dialogue or recitative carries the action forward. At intervals, the action stops and the characters sing arias to express their feelings. An example of the use of recitative and aria appears in the following passage from Wolfgang Amadeus Mozart's opera *Don Giovanni.* In the passage, a character sings several lines of recitative, ending with:

> Every means must be sought to
> discover the truth . . . I shall avenge her!

He then sings an aria that begins with these lines:

> My peace depends on hers; that which
> pleases her gives life to me. . . .

The recitative above tells the audience about the character's future actions. The aria expresses his state of mind. The original Italian text for this aria was written in rhymed poetry.

Ensembles. In many operas, the libretto calls for two or more singers to engage in a musical dialogue, called an *ensemble.* The singers themselves are also called an *ensemble.* The most common ensembles are duets, trios, quartets, and quintets.

Some ensembles require several characters to sing at the same time and express their thoughts and feelings. They may sing the same words, showing agreement. Or they may sing different words and melodies, expressing conflicting feelings and thoughts.

Scene from a production by the Lyric Opera of Chicago, with Regina Resnik, *left,* Joan Sutherland, *center,* and Spiro Malas (WORLD BOOK photo)

An opera ensemble is a small group of singers. The music they sing is also called an *ensemble.* A countess, her daughter, and a soldier sing a lively, comic ensemble in this scene from Act II of *The Daughter of the Regiment* by Gaetano Donizetti.

The music

The singers. In an opera, each role calls for a singer with a specific voice range. Opera singers are therefore classified according to the range of their voices.

The basic vocal classifications for women, from highest to lowest range, are soprano, mezzo-soprano, and contralto. Each of these classifications can be divided into more specialized groups. For example, sopranos can be divided into coloratura sopranos, lyric sopranos, and dramatic sopranos. Coloratura sopranos have a very high range and can sing with great agility. Lyric sopranos have a light, graceful voice appropriate to youthful roles. Dramatic sopranos have a rich, strong voice suited to highly emotional parts.

The chief voice classifications for men, from highest to lowest range, are tenor, baritone, and bass. Each classification can be divided into more specialized groups. For example, tenors can be divided into lyric tenors and dramatic, or heroic, tenors. A lyric tenor has a light, high voice. A dramatic tenor, often called by the German word *Heldentenor,* has a rich, powerful voice with a lower range than a lyric tenor. Such voices are needed for the heroic roles in operas by Richard Wagner. Bass voices are classified as basso cantante, basso buffo, or basso profundo. A basso cantante has the highest bass voice, with a character similar to that of a lyric tenor. A basso buffo has a deep, flexible voice and sings comic roles. A basso profundo has an especially low voice and usually sings majestic, serious roles.

Choral singing. Most operas include choral singing as well as arias, recitatives, and ensembles. The function and importance of the chorus vary from opera to opera and even within an opera. A chorus may provide only visual background for a scene. For example, it might portray a crowd at a festival. Or a chorus may be required merely to shout an exclamation, such as "Hail to our great king!" But in some works, the chorus plays a leading part in the story and sings complicated music.

Scene from a production by the Lyric Opera of Chicago (WORLD BOOK photo)

An opera chorus is a large group of singers who perform as a unit. Members must be able to act expressively while they sing. The chorus above portrays an excited crowd outside a bull ring in a scene from Act IV of *Carmen* by Georges Bizet.

Acting in opera. For a successful career in opera, a singer must have acting skill in addition to an outstanding voice. Most young singers who plan a career in opera take several years of acting lessons.

Opera acting presents special problems because it is difficult to act and sing at the same time. Sudden movements, walking, running, and twisted body positions may all interfere with the production of a beautiful, clear, and steady tone. For this reason, opera acting tends to be less lively and less realistic than acting in other forms of drama.

The conductor plays a key role in opera. Throughout a performance, the conductor must keep the singers and orchestra together. The beat must be clearly seen by singers far from the conductor and by musicians sitting in the dim light at the ends of the orchestra pit. Although the conductor sets the tempo, he or she must be able to react to unexpected circumstances. If a soloist begins to sing faster, for example, the conductor may have to adjust the orchestra's tempo. Because of all these special demands, opera conducting requires greater skills than does any other kind of conducting.

Bruno Bartoletti conducting the orchestra of the Lyric Opera of Chicago (WORLD BOOK photo)

The conductor sets the tempo for both the musicians in the orchestra pit and the singers onstage. He or she must keep the orchestra and vocalists together. The conductor must also adjust the *balance* (loudness) between the singers and the orchestra.

Some operas call for scenes in which musicians and singers perform offstage. In such instances, an assistant conductor directs the offstage music. In some modern opera houses, the assistant conductor directs the offstage music while following the conductor's beat over closed-circuit television.

The orchestra. The number and kinds of instruments in the orchestra depend on the opera being performed. The instruments needed for Italian operas composed in the late 1700's differ greatly from those needed for operas written by Wagner in the late 1800's.

The particular opera being performed also determines the orchestra's function. In most operas, the orchestra's basic job is to accompany the singers. The accompaniment may be simple, providing only enough harmonic and rhythmic background to keep the singers on pitch and in time. But the orchestra may also serve a more important role. For example, it might play music that introduces the general emotional quality of an aria before a note has been sung. The orchestra may even emphasize a passage in the text. For example, a heavily rhythmic beat might accompany the words "my heart pounds faster."

In some scenes, one or more characters may be alone a long time without singing or speaking. During that period, the orchestral music expresses their feelings. This kind of characterization through music is one of the strengths of opera and is impossible in spoken plays.

In many operas, the orchestra often repeats a melody or short theme from an earlier scene. This melody or theme, without singing or spoken words, is called a *leitmotif.* Composers repeat the leitmotif to remind listeners of some action, character, or idea previously introduced in the opera. Composers of the 1800's, notably Wagner, used the leitmotif most effectively.

Pieces of orchestral music called *interludes* are used to connect scenes. Interludes provide time for scenery changes or for new characters to enter. Interludes also may indicate shifts in the emotional atmosphere in an opera. Occasionally, orchestral music imitates the sounds of nature. In Wagner's *Siegfried,* the orchestra imitates the sounds in a forest.

Most operas begin with an orchestral overture. Some overtures merely indicate that the performance is about to begin. But others have a more important function. Some introduce the opera's principal melodies. Others set the mood for the opening scene or for the opera in general. In some older operas, the overture is uncomplicated and brief. A number of overtures of the 1800's are elaborate pieces that run 10 minutes or longer.

Musicians occasionally perform onstage in costume and participate in the action of the opera. For example, musicians may take part in such onstage activities as a military parade or a religious procession.

Producing an opera

An opera company produces several operas in a season. In selecting each work for production, the company must consider several factors. These factors include the estimated cost of presenting the opera and whether the work will attract a large audience. Most opera companies attempt to balance their season with both comic and tragic operas. They also try to select works by a variety of composers and from different historical periods.

The people behind the scenes

During an opera performance, the audience sees only the conductor, orchestra, and performers. But an opera production also requires the skills of many other people. These people include (1) the general manager, (2) the stage director, (3) costume and set designers, (4) the members of the technical staff, and (5) the stage manager. All these specialists perform about the same work for an opera as they would for a spoken play. But opera requires that they coordinate all parts of the production with the music.

The general manager supervises the overall artistic and business policy of the opera company. This person plays a major part in choosing the repertoire and in hiring singers, conductors, and stage managers. The general manager follows each production through the planning and rehearsal stages to make sure it is progressing satisfactorily. Some companies have a music director or artistic director who controls the hiring of singers and conductors.

The stage director is responsible for the visual aspects of an opera production, just as the conductor is responsible for the music. The stage director must coordinate every action on the stage with the music. The director helps singers interpret their roles, works with the designers on ideas for costumes and sets, and helps determine the lighting. See **Theater** (The director).

The stage director faces one of the greatest challenges in handling choral scenes. The chorus should not simply stand still and look at the conductor while singing. All dramatic illusion would be lost. The director must assign all members of the chorus some activity so they will appear natural on the stage. Some operas have scenes in which the chorus takes part in vigorous action while singing. One such scene takes place near the end of Act II of Wagner's opera *The Mastersingers of Nuremberg.* A riot breaks out among a crowd of angry townspeople played by the chorus. In such scenes, the chorus must act convincingly while singing and following the conductor. The stage director has to plan choral scenes like these carefully and then rehearse the scenes frequently.

Sometimes, a stage director may create a new interpretation of an opera. Because the repertoire of opera companies consists chiefly of a few dozen works performed repeatedly, audiences may welcome a production that presents a familiar opera in a fresh way. But some directors have been criticized for taking too many liberties with an opera, for example, by setting it in a different historical period.

The designers. The story of most operas in the standard repertoire takes place before the 1900's. Therefore, the costume and set designers must generally research the particular period of the story so their designs accurately reflect the time and place of the action. In Giuseppe Verdi's *Aida,* for example, the costumes and sets should realistically portray ancient Egypt.

The costumes and sets should be designed so that the performers can move about freely. In addition, the set designer always has to consider the requirements of the music. For example, the music may allow a singer a certain amount of time to move from a door to a table and begin an aria. The designer must arrange the set so the singer can move naturally and still arrive at the table at the precise moment in the music when the aria be-

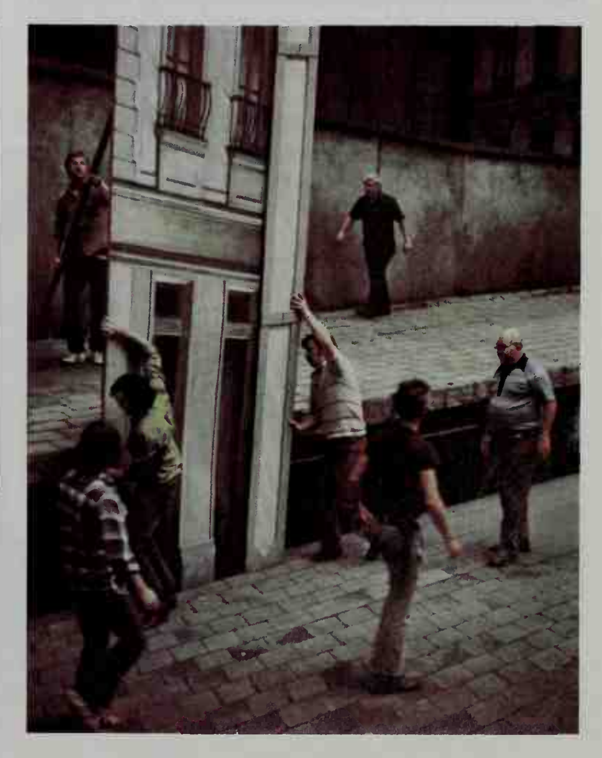
Opera rehearsals involve both technicians and performers. At a lighting rehearsal, *left,* an electrician in a lighting booth works with the director onstage to create desired lighting effects. The director also rehearses the singers, *right,* to develop stage movements and interpretations of roles.

gins. The set designer may also have to plan the sets to provide space for large choral or dance scenes. See **Theater** (Scene design; Costumes and makeup).



The technical staff. Many technicians work with the stage director in planning and carrying out the visual aspects of the production. The electricians are especially important members of the technical staff. They operate the complicated lighting equipment that is used to illuminate parts or all of the stage and to provide atmosphere. Some stage directors rely on lighting, rather than on realistic sets, to express an opera's mood. See **Theater** (Lighting and sound).

During an opera performance, the various crews of technicians and stagehands must work quickly, quietly, and efficiently backstage. One crew changes the scenery between acts or scenes. Another crew adds the small

The prompter speaks the entire libretto during a performance in case a singer forgets a line. He works in a *prompter's box* below the stage where only the singers can see him. The prompter follows the conductor over closed-circuit television.

objects, called *props,* that the performers use in the action. A third crew sets up and adjusts the lights. For changing scenery, some opera houses use revolving stages or stages that can be raised or lowered by elevator. Special technicians operate the machinery that moves these stages. See **Theater** (Changing scenery).

The stage manager has charge of all backstage activity during a performance. He or she sees that all the props needed for a scene are on the stage and in the correct place. The stage manager calls the performers from their dressing rooms at specific times so they can make their entrances on schedule. The stage manager also gives the electricians cues to change the lighting during the performance.

Preparing a production

Planning a production. After a company selects an opera, the general manager and the management staff establish the production's budget. They also choose the cast and assign a stage director and conductor to the production. Most companies employ a resident group of singers, conductors, and directors for an entire season. However, nearly all companies also hire guest singers to take the leading roles for a single production. In addition, companies frequently use guest conductors, stage directors, and designers.

In some cases, the most important consideration in selecting an opera is whether a company can hire a particular guest singer. Sometimes a company wants a certain singer so much it will let the artist choose the opera. In casting the leading parts, the opera company first of all seeks singers who have outstanding voices. But the performers should also act well and, preferably, have the physical appearance suited to the characters they are to portray.

During the early stages of a production, the key personnel hold many conferences. The stage director, for example, meets frequently with the costume and set designers. Sketches of the designs must be approved early to allow enough time for the costumes and sets to be made. The costumes and sets may be manufactured in the opera house workshops or by outside firms. Sometimes, sets and costumes are borrowed or rented from another opera company.

Rehearsing a production. After many months of planning the production, rehearsals begin. At first, the singers, chorus, and orchestra rehearse separately in rehearsal rooms. If the opera calls for dancing, the dancers also practice by themselves.

The stage director rehearses the principal singers to work out stage movements and establish interpretations of the roles. The chorus rehearses under the direction of a chorus master. A *choreographer* (dance creator) supervises dance rehearsals. The conductor and the conductor's assistants rehearse the orchestra.

A few weeks before the opera is to open, rehearsals move from separate facilities to the main stage. These rehearsals take place with piano accompaniment only.

Meanwhile, the stage director and the chief electrician hold lighting rehearsals. In most operas, directors use elaborate lighting that is changed frequently during the performance. Lighting rehearsals develop the best ways to achieve desired effects. The rehearsals also set the timing for the various lighting changes.

As the opening nears, the orchestra rehearses with the entire cast on the main stage. Because of the central function of the music, the conductor takes charge of these rehearsals.

A few days before opening night, the performers and orchestra stage a dress rehearsal. A dress rehearsal is presented like an actual performance, with costumes, makeup, and sets. By this time, the production should move with split-second timing. The music sets the pace for the action and should not have to be sped up or slowed down to adjust to what happens onstage.

Lyric Opera of Chicago (WORLD BOOK photo)

Offstage music is required in some operas. An assistant conductor leads the musicians and singers hidden in the wings. He conducts from a score while following the beat of the conductor in the orchestra pit over closed-circuit television.

The first operas were composed and performed in the 1590's in Florence, Italy. There, a group of noblemen, musicians, and poets had become interested in the culture of ancient Greece, especially Greek drama. This group, called the *Camerata,* believed that the Greeks sang rather than spoke their tragedies. The Camerata attempted to re-create the style of ancient Greek tragedy in music. They took most of their subjects from Greek and Roman history and mythology. The Camerata called their compositions *dramma per musica* (drama for music) or *opera in musica* (musical work). The term *opera* comes from the shortened form of opera in musica. Jacopo Peri, a member of the Camerata, composed what is generally considered to be the first opera, *La Dafne* (1597).

Baroque opera

Opera emerged as an art form in western Europe during the *baroque* period in music history. This period began about 1600 and ended about 1750. Baroque music was elaborate and emotional. Italians composed the earliest baroque operas, and Italian-style opera dominated most of the period.

Early baroque opera. The first baroque operas consisted of recitatives, sung by soloists, and choral passages. A small orchestra accompanied the singers.

During the 1600's, the aria gradually emerged and developed as a separate function from that of the recitative. The recitative served to carry the plot of the opera forward. The arias became pauses in the action in which characters expressed their thoughts and feelings. Singers often used arias for showing off their vocal skills rather than for dramatic expression. A very common form of presentation called *simple recitative* developed in the 1600's. In it, the singers were accompanied by only a harpsichord—or by a harpsichord and cello or other bass instrument—rather than by the full orchestra.

Claudio Monteverdi, the first great composer of baroque opera, wrote the first opera masterpiece, *Orfeo* (1607). Later Monteverdi worked in Venice and made it the center of opera during the early 1600's. The world's first public opera house, the Teatro San Cassiano, opened in Venice in 1637.

By the late 1600's, operas were being written and performed in a number of European countries outside Italy, especially in England, France, and Germany. Italian opera was the accepted style, and many non-Italian composers wrote operas in the Italian manner and to Italian librettos.

Opera seria and opera buffa. Italian opera of the early 1700's developed into two basic types— (1) *opera seria* (serious opera) and (2) *opera buffa* (comic opera). Both types consisted of a succession of recitatives and arias.

Opera seria. Composers of opera seria based their works on stories of ancient heroes and heroines. In the 1600's, similar stories had included both comic and serious characters. They had provided spectacular stage effects, such as earthquakes and floods and big coronation or battle scenes. But comic scenes and spectacle were eliminated from serious opera in the 1700's. Emphasis fell instead on the skills of the principal singers. By the 1800's, many singers were trained in a vocal style called *bel canto,* which emphasized technical skill and beauty of tone. The *da capo* aria became a major feature of opera seria. It had three parts, the third being a repetition of the first. In the repeated part, the singer was expected to add difficult passages and other ornamentation not included in the score.

Opera buffa began as comic skits, called *intermezzi,* performed in front of the curtain between the acts of an opera seria. The characters in opera buffa were common people, unlike the characters in opera seria. Characters in opera buffa represented the professions and

Engraving by Stefano della Bella of a scene from *The Wedding of the Gods* (1637) by Giovanni Carlo Coppola; The Newberry Library, Chicago

Opera in Italy during the 1600's called for spectacular scenery and often dealt with ancient heroes and heroines. The Italian designer Alfonso Parigi created the elaborate set at the left for an opera seria. It shows the workshop of Vulcan, the blacksmith to the gods in Roman mythology. Parigi designed the workshop as a cave at the foot of several towering cliffs.

social classes of the time, including doctors, farmers, merchants, servants, and soldiers. The typical opera buffa dealt with humorous situations from everyday life. Many characters in opera buffa sang in *dialects* (local forms) of Italian rather than the formal Italian of opera seria. A very successful intermezzo was *La serva padrona* (1733) by Giovanni Pergolesi.

Italian opera seria and opera buffa were extremely popular. Hundreds of them were written, often in a short time. Most of these works were performed for one season and then forgotten. Because of the constant demand for new operas, composers used the same librettos over and over again. By today's standards, many librettos had unconvincing plots and unbelievable characters. Although some operagoers complained about the weak librettos of many Italian operas, most audiences of the 1600's and early 1700's enjoyed the works, chiefly for their music.

French opera. A distinctly French style of opera appeared in the 1670's. Before that time, the French showed little interest in opera. The few operas performed in the country were written in the Italian style. Jean-Baptiste Lully, though born in Italy, established a French form of opera. In the mid-1700's, Jean-Philippe Rameau became the leading composer of French opera.

French opera composers avoided the rapid recitatives and showy arias of Italian opera. Instead they preferred expressive melodies or simple songs. The recitatives were accompanied by a full orchestra and closely followed the rhythms of the French language. Ballet played an important part in French opera during the baroque period, as well as later.

In France, royalty became the chief patrons of opera. Lully acquired his fame at the court of King Louis XIV. The nobility in France and other countries competed with one another in maintaining large opera companies. To impress audiences with their wealth, the nobility sponsored productions noted for expensive scenic effects, such as gods riding chariots in the sky.

Classical opera

Dissatisfaction with Italian opera began to spread among operagoers during the mid-1700's. Attacks centered on the increasingly long and dramatically weak arias, which served only to glorify the singers. The reaction against Italian opera led to a series of reforms early in the classical period. The classical period began about 1750 and lasted about 70 years. The first important classical opera composer was Christoph Willibald Gluck, a German. The greatest classical composer was Wolfgang Amadeus Mozart, an Austrian.

Gluck and opera reform. Gluck believed drama and music should be unified in opera. By integrating the music with the story in *Orpheus and Eurydice* (1762) and other works, he put his beliefs into practice.

Gluck rejected improbable plots and emphasis on showy arias. In his operas, the music served the story. Gluck simplified the action to make the stories and characters appear more natural. He also was one of the first composers to supervise all aspects of a production.

Mozart, like Gluck, felt that the music in an opera should help make the story and characters believable. Mozart achieved this goal by carefully relating the instrumental and vocal music to the action. He showed particular skill in using music to create characterization—that is, to develop the personality of the characters. Mozart did this in ensemble scenes and in arias.

Mozart composed operas in both Italian and German. His best-known Italian operas are *The Marriage of Figaro* (1786), *Don Giovanni* (1787), and *Così Fan Tutte* (1790). His notable German operas include *The Abduction from the Seraglio* (1782) and *The Magic Flute* (1791). Both of these works contain elements of *Singspiel* (sung play). Singspiel is a form of German opera that has spoken dialogue rather than recitative. Most stories are comic. The melodies often are simple and resemble the style of German folk and popular songs.

Opera in the 1800's

Romanticism was a movement from the late 1700's to the mid-1800's that emphasized emotionalism in the arts, including opera. The typical romantic opera had a setting in nature, a theme based on folklore or the supernatural, and colorful music. Carl Maria von Weber, a German, wrote one of the earliest and greatest romantic operas, *Der Freischütz* (1821). The story is set in Germany's Black Forest, and most of the chief characters are simple countrypeople. The orchestra has an important part in portraying many of the sounds of nature as well as supernatural forces.

Several Italians also created a romantic style of opera. The most successful of these composers were Vincenzo Bellini and Gaetano Donizetti. Many of their operas require voices trained in the bel canto style.

Grand opera became popular in the early 1800's, especially in France. Composers of grand opera favored heroic episodes from history, in which they could use crowd scenes, spectacular stage effects, and complicated and elaborate vocal and instrumental music. Giacomo Meyerbeer, a German, became the leading composer of French grand opera with such works as *Les Huguenots* (1836) and *Le Prophète* (1849). Gioacchino Rossini, an Italian-born composer living in France, also wrote a famous grand opera, *William Tell* (1829).

Giuseppe Verdi dominated Italian opera during the mid- and late 1800's. He is still perhaps the most popular opera composer in history. Verdi's best-known works include *Rigoletto* (1851), *Il Trovatore* (1853), *La Traviata* (1853), and *Aida* (1871). All are noted for their emotional power, which is expressed through eloquent vocal music. *Aida* is also an example of grand opera.

Verdi wrote his last two operas—*Otello* (1887) and *Falstaff* (1893)—when he was in his 70's. Both works demonstrate that old age did not diminish but rather refined his genius. The operas are masterpieces of characterization through music, and they show complete fluidity of vocal and instrumental writing.

Richard Wagner was the most important German opera composer of the 1800's. Wagner believed that all the parts of an opera production—acting, costumes, drama, orchestral music, singing, and staging—should have equal value. He wrote his own librettos and, whenever possible, supervised the staging of a production. Wagner departed from tradition by making the orches-

tra as important as the singers. In many of Wagner's late works, instruments perform the main melodies.

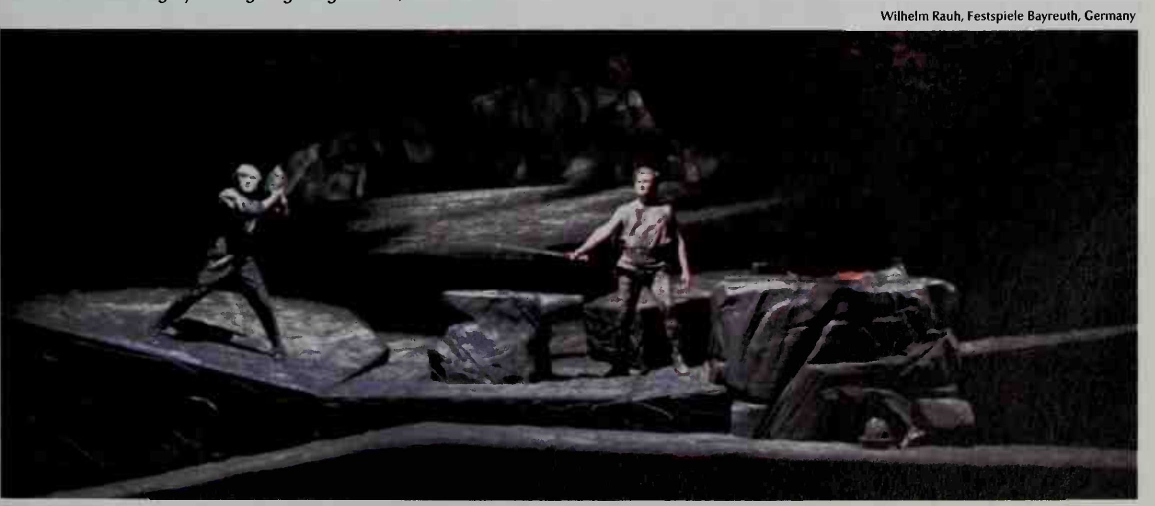
As a young man, Wagner was greatly impressed by Weber's romantic opera *Der Freischütz*. *The Flying Dutchman* (1843), one of Wagner's early works, shows similar romantic qualities. These qualities include the supernatural aspects of the plot and the musical representation of the forces of nature, such as the wind and the sea. In *The Flying Dutchman,* Wagner first used musical themes to identify certain characters, places, or ideas each time they appear in the drama. Wagner expanded this *leitmotif* technique greatly in his later operas. *Tristan and Isolde* (1865) and the four works called *The Ring of the Nibelung* (1876) represent Wagner's fully developed personal style.

Nationalism influenced many composers throughout Europe during the 1800's. These composers based much of their work on the folk music of their nation or region. Czech nationalism, for example, dominates the operas of Antonín Dvořák and Bedřich Smetana. *The Bartered Bride* (1866) by Smetana and *Rusalka* (1901) by Dvořák are outstanding examples of nationalistic operas. Russian composers of nationalistic operas include Modest Mussorgsky with *Boris Godunov* (1874) and Alexander Borodin with *Prince Igor* (1890).

Verismo opera. In the late 1800's, some Italian composers began to write grimly realistic operas. These *verismo* (meaning true or realistic) operas focused on violent emotions and actions. The earliest and best-known verismo operas are *Cavalleria Rusticana* (1890) by Pietro Mascagni and *Pagliacci* (1892) by Ruggiero Leoncavallo, both one-act works usually performed together.

Festspiele Bayreuth, Germany

New techniques in staging have given a fresh interpretation to many older operas. At its première in 1876, Richard Wagner's opera *Siegfried* was presented in a realistic setting, *above.* A modern staging of the work eliminates the detailed scenery and achieves mood largely through lighting effects, *below.*



The 1900's

Giacomo Puccini was the most popular Italian opera composer of the early 1900's. His operas are noted for their melodic and sometimes sentimental music and for their theatrically effective librettos. Puccini first gained widespread attention in the 1890's with *Manon Lescaut* (1893) and *La Bohème* (1896). He followed these works with *Tosca* (1900), a verismo opera. His other notable operas include *Madama Butterfly* (1904) and *Turandot* (produced in 1926, after his death).

Richard Strauss became the most important and successful German opera composer after Wagner. Strauss wrote operas that require singers with great vocal power. He is best known for three early operas—*Salome* (1905), *Elektra* (1909), and *Der Rosenkavalier* (1911). *Salome* and *Elektra* originally caused much controversy among operagoers because of their brutal action and harsh music. *Der Rosenkavalier,* however, is entirely different in mood and theme. In this opera, Strauss and the librettist, Hugo von Hofmannsthal, created an affectionate portrait of aristocratic society in Vienna in the 1700's.

The search for new forms. After World War I (1914-1918), many composers began to search for new forms of operatic expression. Some composers included ele-

Bomarzo by Alberto Ginastera is one of the few modern operas to win international fame. The tragic opera concerns the tortured mental state of Duke Bomarzo, a deformed Italian nobleman. Bomarzo and his grandmother, *shown here,* sing a duet.

ments of American jazz in their operas. Ernst Křenek, an Austrian, used jazz in his opera *Jonny spielt auf* (1927). The German composer Kurt Weill wrote *The Threepenny Opera* (1928) in the style of the music heard in German *cabarets* (nightclubs).

Meanwhile, a movement called *Expressionism* had developed in the arts. Expressionism aimed at exploring the subconscious and became especially important in drama and painting. But Expressionist qualities also appeared in several operas. Such operas had a brooding, nightmarish atmosphere, reinforced by dissonant music and symbolic and violent actions.

Strauss's *Salome* was an early example of the Expressionist style. But Alban Berg, an Austrian composer, ranks as the leading opera composer in the movement. Berg wrote *Wozzeck* (1925), the most successful Expressionistic opera. Other operas related to Expressionism include *Duke Bluebeard's Castle* (completed 1911, first performed 1918) by the Hungarian composer Béla Bartók and *From the House of the Dead* (1930) by the Czech composer Leoš Janáček.

Some of the most successful and theatrically effective operas of the 1900's were written by the British composer Benjamin Britten. His opera *Peter Grimes* (1945) is a brooding but lyrical portrait of social alienation.

American opera. American composers wrote no important operas until the 1900's. George Gershwin wrote a highly original and popular American opera, *Porgy and Bess* (1935). The work describes life among blacks in Charleston, South Carolina, in the 1920's. *Porgy and Bess* has been acclaimed worldwide as a genuine American folk opera.

The most successful opera composer in the United States is Gian Carlo Menotti. He composes in a traditional style that shows the influence of Puccini. Menotti wrote an opera for radio, *The Old Maid and the Thief* (1939), and an opera for television, *Amahl and the Night Visitors* (1951). His best-known stage operas include two tense dramas, *The Medium* (1946) and *The Consul* (1950).

Since World War II (1939-1945), the best operas have been written by more tradition-minded composers. They include Douglas Moore's folk-inspired *The Ballad of Baby Doe* (1956) and Virgil Thomson's *The Mother of Us All* (1947). The text for *The Mother of Us All* was written by American author Gertrude Stein.

Opera has played only a minor role in modern American experimental music. Some Americans associated with the *Minimalist* movement have written several important operas. The Minimalist style uses repeated short patterns of music with complex rhythmic variations but simple harmonies. Operas in this style include Phillip Glass's *Einstein on the Beach* (1975), which draws on rock music, and John Adams's *Nixon in China* (1987).

Opera today

The experimentation in opera that began after World War I continues today. Some composers have explored new dramatic and musical techniques, including the use of electronic sounds, motion pictures, and color slides. *Aniara* (1959), a science-fiction opera by the Swedish composer Karl-Birger Blomdahl, takes place in a spaceship and uses taped and electronic sounds. *Bomarzo* (1967) by the Argentine composer Alberto Ginastera also features unconventional sound effects, especially in fantastic, dreamlike scenes.

Operagoers today, however, still prefer older, traditional works. Only a few operas composed since the end of World War I receive frequent productions. But many changes have occurred in the way older operas are staged. For example, stage directors often try to create desired moods through lighting effects made possible by modern lighting equipment.

Meanwhile, artistic and economic problems trouble all major opera companies. Before the development of fast, convenient air travel, leading singers remained with one company an entire season. But jet travel enables singers to appear as guest artists in many opera houses in a season. Artists earn more money as guests, and audiences can see and hear many famous singers. However, traveling artists often follow a tight, exhausting schedule that leaves too little time for rehearsal. As a result, audiences often attend performances that show a lack of adequate preparation.

The cost of producing opera has risen steadily. Even if an opera house sells every ticket for an entire season, it cannot meet expenses. Ticket sales seldom provide more than half the income needed to operate an opera company. American companies rely on contributions from individuals, corporations, and foundations to make up losses. Many European countries, cities, and states support opera with public funds. Numerous people in the United States believe the national government or local governments should help support opera and the other arts, as governments do in Europe.

Most U.S. colleges and universities have opera workshops. They provide training and experience for young singers and also present performances for the general public. Some colleges and universities have staged revivals of worthwhile but little-known works.

Opera companies today present mainly works that were composed between the late 1700's and the early 1900's. Almost all the operas in this standard repertoire were written by Austrian, French, German, Italian, and Russian composers. This section describes some of the most popular operas in the standard repertoire. Some of the recommended books that are listed at the end of this article provide more detailed discussions of the repertoire.

Aida, a tragic opera in four acts by Giuseppe Verdi. Libretto in Italian by Verdi and Antonio Ghislanzoni. First performed in Cairo, Egypt, in 1871.

The *khedive* (ruler) of Egypt asked Verdi to write *Aida* to help celebrate the opening of the Suez Canal and the Cairo opera house. The story takes place in ancient Egypt and concerns the tragic love affair between Aida, an Ethiopian slave, and Radames, an Egyptian military officer. *Aida* is grand opera and so requires a large cast. The work has impressive crowd scenes, featuring choruses of soldiers, slaves, and priests, and an elaborate ballet. In Act I, Radames expresses his love for Aida in a beautiful aria, "Celeste Aida." Act II includes the stirring "Triumphal March," in which the Egyptian king reviews his victorious army.

Barber of Seville, The (*Il Barbiere di Siviglia*), a comic opera in two acts by Gioacchino Rossini. Libretto in Italian by Cesare Sterbini, based on the French play *The Barber of Seville* by Pierre de Beaumarchais. First performed in Rome in 1816.

The story of *The Barber of Seville* takes place in Seville, Spain, in the 1600's. This work is a good example of Italian comic opera, or *opera buffa.* The libretto has many characters and situations typical of this style. The characters include an old man called Doctor Bartolo who is interested in a beautiful and rich young woman named Rosina. He jealously watches over her but cannot prevent a dashing young nobleman (Count Almaviva) from meeting and finally marrying her. Other traditional characters include a drunken soldier, who is really the count in disguise, and an irritable housekeeper. Figaro, the barber in the opera's title, helps the count win Rosina.

In Act I, Rosina's aria "Una voce poco fa" provides opportunities for brilliant singing. Also in Act I, Figaro makes his first appearance singing a popular comic aria, "Largo al factotum," in which he boasts how clever he is. The opera also has a lively overture, which Rossini had used in two earlier operas.

Bohème, La (*The Bohemian*), a tragic opera in four acts by Giacomo Puccini. Libretto in Italian by Giuseppe Giacosa and Luigi Illica, based on the French novel *Scenes from Bohemian Life* by Henri Murger. First performed in Turin, Italy, in 1896.

Four poor but carefree young men are living a bohemian life together in an attic in Paris about 1830. They are Rodolfo, a poet; Marcello, a painter; Schaunard, a musician; and Colline, a philosopher. Mimi, a frail young girl in poor health, is their neighbor. She and Rodolfo meet and fall in love. But at the end of the opera, Mimi dies. The main secondary plot deals with a stormy love affair between Marcello and a young woman named Musetta.

Although *La Bohème* ends tragically, it has many humorous and sentimental moments. The opera also has a number of Puccini's most beloved melodies. One of these melodies is "O soave fanciulla," a love duet between Rodolfo and Mimi that ends Act I. Perhaps the opera's most familiar melody is the aria "Musetta's Waltz" in Act II.

Boris Godunov, a tragic opera in a prologue and four acts by Modest Mussorgsky. Libretto in Russian by the composer, based primarily on the Russian play *Boris Godunov* by Alexander Pushkin. First performed in St. Petersburg, Russia, in 1874.

The opera takes place in Russia and Poland from 1598 to 1605 and concerns Russian historical figures. Boris

Scene from a production by the New York City Opera; Beth Bergman

The Barber of Seville by Gioacchino Rossini is one of the most popular comic operas. Act I ends in the wild argument shown here between Doctor Bartolo, *left center,* and Count Almaviva, *right center,* who is masquerading as a drunken soldier. Don Basilio, a music teacher, and Berta, a maid, try to hold back the doctor. Figaro, a barber, and Rosina, the count's sweetheart, attempt to restrain the nobleman.

Scene from a production by the Lyric Opera of Chicago, with Luciano Pavarotti and Ileana Cotrubas (WORLD BOOK photo)

La Bohème by Giacomo Puccini deals with a love affair between Rodolfo, a poet, and Mimi, a young seamstress in failing health. Near the end of Act IV, *above,* Rodolfo and the dying Mimi sing a beautiful love duet in the poet's attic lodging.

Godunov, an adviser to the czar, has the czar's young heir murdered. After the czar dies, Boris takes the throne. But in time, his feelings of guilt cause him to have visions of the murdered heir, and he finally collapses and dies. The "hero" of the opera is the Russian people, portrayed by the chorus. The chorus takes part in many scenes, including an impressive coronation.

Many musicians in Mussorgsky's time considered the music for *Boris Godunov* too harsh and crude. After Mussorgsky's death, his friend and fellow Russian composer Nikolai Rimsky-Korsakov revised the orchestration for the opera. Rimsky-Korsakov's version is often performed today.

Carmen, a tragic opera in four acts by Georges Bizet. Libretto in French by Ludovic Halévy and Henri Meilhac, based on the French story "Carmen" by Prosper Mérimée. First performed in Paris in 1875.

The action of *Carmen* is set in and near Seville, Spain, about 1820. Carmen is a beautiful Gypsy dedicated to a life of unrestrained freedom. While working in a cigarette factory in Seville, she meets Don José, a soldier, and has a love affair with him. Later, she leaves Don José for Escamillo, a bullfighter. At the end of the opera, Don José pleads with Carmen to return to him. After she scornfully refuses, Don José stabs her to death in a jealous rage.

The exciting plot, colorful Spanish setting, and stirring music have made *Carmen* one of the most popular works in the repertoire. Many of the opera's melodies have become almost as familiar as popular songs. They

Scene from a production by the Bolshoi Theater Company, Moscow; Novosti Press Agency, Moscow

Boris Godunov by Modest Mussorgsky is a psychological tragedy based on events in Russian history. In the prologue to the opera, *above,* Russian peasants in Moscow bow before Boris shortly after he has been crowned czar. Members of the Russian nobility stand behind him.

include Carmen's dancelike arias "Habañera" and "Seguidilla" in Act I and Don José's "Flower Song" and Escamillo's "Toreador Song" in Act II. The opera also has rousing choral and dance numbers.

Cavalleria rusticana (*Rustic Chivalry*), a tragic opera in one act by Pietro Mascagni. Libretto in Italian by Guido Menasci and Giovanni Targioni-Tozzetti, based on the Italian story and play *Cavalleria rusticana* by Giovanni Verga. First performed in Rome in 1890.

Traditionally, *Cavalleria rusticana* is performed with Ruggiero Leoncavallo's two-act opera, *Pagliacci*. The passion, realism, and violence of both works make them major examples of verismo opera.

The action in *Cavalleria rusticana* takes place in a Sicilian village in the 1800's. There, Lola, a married woman, has a love affair with Turiddu, a young soldier. The title of the opera refers to the villagers' code of honor. According to this code, Alfio, Lola's husband, must seek revenge. He challenges Turiddu to a duel and kills him.

The composer and librettists used several effective dramatic devices. Halfway through the opera, the villagers are in church, and the stage is empty. During this interval, the orchestra plays the "Intermezzo." This gentle, melodic instrumental piece provides relief from the tense, highly emotional atmosphere of the opera. In another dramatic device, Turiddu's death takes place offstage. The opera audience learns of the outcome of the duel through the horrified reactions of the villagers onstage.

Don Giovanni, a comic opera with serious elements in two acts by Wolfgang Amadeus Mozart. Libretto in Italian by Lorenzo da Ponte. First performed in Prague, Bohemia (now part of the Czech Republic), in 1787.

Mozart's opera *Don Giovanni* has become the best-known version of the legend about Don Juan, the Spanish rogue. The action takes place in and near Seville, Spain, in the 1600's. In the opening scene, Don Giovanni (Don Juan) flees from the home of Donna Anna after trying to seduce her, and then he kills her father in a duel. Several later episodes further show Giovanni's immoral nature. At the end of the opera, the marble statue of Donna Anna's slain father visits Giovanni and urges him to abandon his sinful ways. Giovanni refuses. The scene is then enveloped in smoke and fire as he disappears into hell, dragged off by a chorus of demons.

The mixture of comic and serious qualities of *Don Giovanni* has always fascinated audiences. Leporello, Giovanni's servant, provides most of the comedy. The

Scene from a production by the Lyric Opera of Chicago, with Viorica Cortez and Lorenzo Saccomani (WORLD BOOK photo)

Carmen by Georges Bizet describes the love affairs of a beautiful Gypsy. In this scene from Act IV, Carmen sings a duet outside a bull ring with her latest lover, the bullfighter Escamillo.

Scene from a production by the New York City Opera; Beth Bergman

Don Giovanni by Wolfgang Amadeus Mozart has been praised as the greatest opera ever composed. It deals with the legendary Spanish rogue Don Juan (Don Giovanni). Act I ends with this elaborate ball in Giovanni's castle.

most serious figure is Donna Anna. In addition to many beautiful arias, *Don Giovanni* has highly dramatic recitatives and long, complicated ensembles. In one scene in Act I, three orchestras onstage perform three different dance numbers at the same time during a party given by Don Giovanni. While the three onstage orchestras play, the opera orchestra in the pit accompanies the singers.

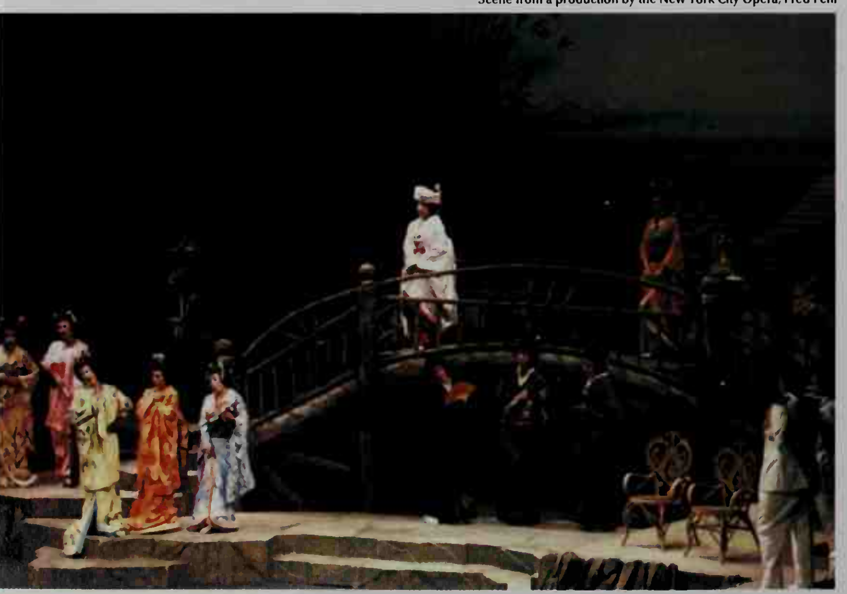
Faust, a tragic opera in five acts by Charles Gounod. Libretto in French by Jules Barbier and Michel Carré, based on part I of the German play *Faust* by Johann Wolfgang von Goethe. First performed in Paris in 1859.

The story of *Faust* takes place in Germany in the 1500's. Faust is an old philosopher who yearns for his lost youth. Mephistopheles, the Devil, appears to Faust and grants him youth. Faust, in return, agrees that after he dies, he will serve the Devil in hell. The opera centers on the love story between the now young Faust and Marguerite, a beautiful village girl. At the end of the opera, Marguerite dies and a chorus of angels escorts her to heaven. The Devil then drags Faust down to hell.

In the 1800's, the German composers Louis Spohr and Heinrich Zöllner and the Italian composer Arrigo Boito also wrote operas based on the story of Faust and his agreement with the Devil. But Gounod's version has become the most popular. The 1859 version had spoken dialogue. Gounod substituted recitative in a production first given in 1869, and that version is performed today. In Act III, Marguerite sings the beautiful "Jewel Song." The lively "Soldiers' Chorus" in Act IV is one of the best-known choral numbers in the entire repertoire.

Lucia di Lammermoor, a tragic opera in three acts by Gaetano Donizetti. Libretto in Italian by Salvatore Cammarano, based on the Scottish novel *The Bride of Lammermoor* by Sir Walter Scott. First performed in Naples, Italy, in 1835.

Donizetti wrote *Lucia di Lammermoor* in the melodramatic style typical of Italian romantic opera of the early 1800's. The story takes place in Scotland in the late 1600's. It concerns a doomed love affair between Lucia Ashton and Edgardo di Ravenswood. Enrico Ashton, Lucia's brother, wrongfully holds Edgardo's estate. To prevent Lucia and Edgardo from marrying, Enrico tricks Lucia into wedding another man. Lucia goes insane, kills her husband, and then dies. Edgardo hears of Lucia's death and stabs himself to death.



The opera has one of the most dramatic ensembles in the repertoire, the sextet "Chi mi frena." It is sung in Act II at Lucia's wedding. But the opera is probably best known for the "Mad Scene" in Act III, in which the insane Lucia sings of an imaginary wedding between herself and Edgardo. This scene is considered one of the greatest challenges for a coloratura soprano in all opera.

Madama Butterfly, a tragic opera in three acts by Giacomo Puccini. Libretto in Italian by Giuseppe Giacosa and Luigi Illica, based on the American play *Madame Butterfly* by David Belasco, from a story by John Luther Long. First performed in Milan, Italy, in 1904.

The story of *Madama Butterfly* takes place in Nagasaki, Japan, about 1900. Cio-cio-san (Madame Butterfly) is a *geisha* (young Japanese woman trained to entertain men) who falls in love with an American naval officer, B. F. Pinkerton. They marry in a Japanese ceremony. According to Japanese law, either the husband or the wife may cancel the marriage on a month's notice. Pinkerton must leave Japan with his ship. After he has left, the young woman gives birth to his child. Three years later, Pinkerton sends a letter saying that he has married an American. Shortly after the letter arrives, Pinkerton appears with his American wife. The heartbroken Cio-cio-san agrees to give them the child. She then commits suicide.

Puccini tried to give *Madama Butterfly* an Oriental flavor by basing some of his score on Japanese music. He also included a passage from "The Star-Spangled Ban-

Scene from a production by the New York City Opera; Fred Fehl

Madama Butterfly by Giacomo Puccini describes a tragic romance between Cio-cio-san, a young Japanese woman, and B. F. Pinkerton, an American naval officer. In Act I, the young woman and her friends arrive for the marriage ceremony. Standing on a bridge in the garden, Cio-cio-san sings of her love for Pinkerton.

The Magic Flute by Wolfgang Amadeus Mozart is a fairy-tale opera. Act II, the final act, ends with this scene in the sacred Temple of Wisdom, ruled by the high priest, Sarastro. Marc Chagall, the famous Russian-born modern artist, designed this set for a production at the Metropolitan Opera House.

Frank Dunand, the Metropolitan Opera Guild

ner" in one of Pinkerton's numbers. The opera's best-known aria is the exquisite "Un bel dì" in Act II. In it, Cio-cio-san describes the happiness she will feel when Pinkerton returns.

Magic Flute, The (*Die Zauberflöte*), a fairy-tale opera in two acts by Wolfgang Amadeus Mozart. Libretto in German by Emanuel Schikaneder. First performed in Vienna, Austria, in 1791.

Mozart and Schikaneder were both members of a secret society called the Masons, and much of *The Magic Flute* deals symbolically with Masonic beliefs and rituals. However, the opera can be enjoyed as a fairy tale about two lovers, Tamino and Pamina. The opera takes its name from a magic flute that protects Tamino from danger.

The opera has spoken dialogue instead of recitative. Some of the music resembles simple folk songs, though several of the arias are dramatic and solemn. The Queen of the Night, Pamina's mother, sings two arias that are showpieces for a coloratura soprano. The arias have very hard passages and high notes. The overture is often performed as a separate work in concerts.

Marriage of Figaro, The (*Le Nozze di Figaro*), a comic opera in four acts by Wolfgang Amadeus Mozart. Libretto in Italian by Lorenzo da Ponte, based on the French play *The Marriage of Figaro* by Pierre de Beaumarchais. First performed in Vienna in 1786.

Beaumarchais wrote *The Barber of Seville* before *The Marriage of Figaro.* Mozart selected the second play for his opera. The Italian composer Giovanni Paisiello had

Scene from a production by the New York City Opera; Fred Fehl

Pagliacci by Ruggiero Leoncavallo is a tragedy about a company of traveling actors who stop in an Italian village to give a performance. In an aria in Act I, Canio, the leader of the company, describes the play the actors will present that night in the village.

already composed an opera based on *The Barber of Seville.* The same principal characters appear in both works. The plot of *The Marriage of Figaro* follows the action begun in *The Barber of Seville.* Mozart's opera describes the problems that develop when Figaro, servant to Count Almaviva, tries to marry Susanna, Countess Almaviva's maid. The Count wants Susanna for himself, but a final scene of multiple disguises brings him back to his wife.

Operagoers have praised *The Marriage of Figaro* for its vivid, realistic characters. Unlike many opera composers of the time, Mozart relied far more on ensembles than on arias to develop his characters.

Pagliacci (*The Players*), a tragic opera in a prologue and two acts by Ruggiero Leoncavallo. Libretto in Italian by the composer. First performed in Milan, Italy, in 1892.

A short verismo opera, *Pagliacci* deals with life among members of a traveling company of actors in Italy in the 1860's. The story concerns the jealousy of Canio, the leader of the players. The opera opens with a prologue sung in front of the curtain by Tonio, who plays a clown. The prologue announces the theme of the drama.

Early in Act I, Canio learns that Nedda, his wife, is unfaithful. He discovers she is having a love affair, but he does not know the identity of the man. Canio sings one of the great tenor arias in all opera, "Vesti la giubba," which expresses his tragic fate of playing a clown while his heart is breaking. During a performance of a play, Canio learns that his wife's lover is Silvio, a peasant who lives in the village where the actors are performing. Canio then stabs Nedda and Silvio as the opera ends.

Porgy and Bess, a folk opera in three acts by George Gershwin. Libretto in English by Gershwin's brother Ira and DuBose Heyward, based on Heyward's novel *Porgy.* First performed in Boston in 1935.

Gershwin's *Porgy and Bess* is one of the few American operas that has achieved worldwide fame. The opera portrays life among black people in Charleston, S.C., in the 1920's. It specifically deals with the love of the crippled Porgy for the beautiful Bess. The story is colorful and highly dramatic, and it has considerable humor. In his score, Gershwin captured the flavor of the songs sung by black people of the Southeastern United States.

The opera consists largely of individual songs and choral scenes, connected by spoken dialogue and some recitative. Some of the songs, including "Summertime," "I Got Plenty o' Nuttin'," and "It Ain't Necessarily So," have become popular hits.

Rigoletto, a tragic opera in three acts by Giuseppe Verdi. Libretto in Italian by Francesco Maria Piave, based on the French play *Le Roi s'amuse* (*The King Is Amused*) by Victor Hugo. First performed in Venice, Italy, in 1851.

The opera tells a story of treachery and revenge in the court of an Italian nobleman, the Duke of Mantua, in the 1500's. The chief characters include the duke; Rigoletto, a hunchback who is the duke's jester; and Gilda, Rigoletto's daughter. Through intrigue and deceit, Rigoletto's beloved daughter is murdered.

For *Rigoletto,* Verdi composed some of his most glorious melodies. In Act I, Gilda sings the beautiful aria "Caro nome," in which she expresses her love for the duke, who is disguised as a student. In Act III, the duke sings one of the most popular arias in the repertoire, "La donna è mobile." The aria is an ironic comment by the faithless duke on how changeable women are in their affections. The emotional and melodic quartet "Bella figlia dell' amore" is sung later in Act III.

Ring of the Nibelung, The (*Der Ring des Nibelungen*), a cycle of four operas by Richard Wagner. Libretto in German by the composer. The three main parts are

Scene from a production by the New York City Opera; Fred Fehl

Der Rosenkavalier by Richard Strauss portrays life among the aristocracy in Vienna during the 1700's. Part of the story concerns a romance between Octavian, a young nobleman, and Sophie, a wealthy young girl. They meet and fall in love in this scene in Act II. Octavian, *center,* brings Sophie, *left,* a silver rose sent by Baron Ochs. The baron, a coarse, middle-aged nobleman, plans to marry Sophie.

Die Walküre (*The Valkyrie,* 1870); *Siegfried* (1876); and *Die Götterdämmerung* (*The Twilight of the Gods,* 1876). Wagner called the fourth work, *Das Rheingold* (*The Rhine Gold,* 1869), the prologue to the other three. However, it is a complete opera. All four works were first performed as a cycle at the opening of the Festival Opera House in Bayreuth, Germany, in 1876.

The four operas have a continuous plot based on ancient German and Icelandic legends. The Rhine-Maidens guard a treasure of gold on the bottom of the Rhine River. Alberich, one of a group of dwarfs called Nibelungs, steals the Rhine gold and makes a ring from it. The ring gives magic powers to whoever possesses it. After the ring is stolen from Alberich, he puts a curse on it. The ring changes owners several times during the four operas.

Many gods and goddesses take part in the action, including Wotan, their chief; and Fricka, his wife. Other important characters include Brünnhilde, one of several female warriors called Valkyries; Siegmund, a mortal son of Wotan; Siegfried, Siegmund's son; and Sieglinde, Siegmund's sister. The Ring cycle deals with the decline and downfall of the gods, brought about by their greed and lust for power as represented by the ring.

Rosenkavalier, Der (*The Cavalier of the Rose*), a partly comic, partly serious opera in three acts by Richard Strauss. Libretto in German by Hugo von Hofmannsthal. First performed in Dresden, Germany, in 1911.

Unlike most opera texts, the libretto for *Der Rosenkavalier* is an outstanding work of literature. It glamorously portrays life among the aristocracy in Vienna in the 1700's. In most productions, the sets for the first two acts are spectacular, representing luxurious Viennese palaces. The work also calls for magnificent costumes.

The opera describes the love affairs of four chief characters: Princess von Werdenberg, called the Marschallin; Octavian, a young nobleman; Sophie, a beautiful girl; and Baron Ochs, a coarse and comic country nobleman. Strauss wrote the role of Octavian to be played by a female, and a mezzo-soprano sings the part.

Strauss composed many brilliant ensemble scenes for *Der Rosenkavalier.* One of the most impressive takes place in Act I when the Marschallin receives many visitors. The composer emphasized the light-hearted Viennese quality of the opera in a number of lilting waltzes. These waltzes are sometimes performed separately in concerts.

Salome, a tragic opera in one act by Richard Strauss. Libretto in German by Hedwig Lachmann; a translation of a play in French, *Salomé,* by the Irish-born author Oscar Wilde. First performed in Dresden, Germany, in 1905.

Wilde based his play on the story of Salome in the New Testament, but he invented many details that shocked audiences of his time. In Wilde's play, Salome, a 15-year-old girl, is attracted to the religious prophet Jochanaan (Saint John the Baptist). After Jochanaan rejects her advances, she decides to take revenge. Salome's stepfather, King Herod, asks her to dance for him and, in return, promises her anything she wishes. Salome performs the famous "Dance of the Seven Veils" and then asks Herod for Jochanaan's head on a silver dish. Herod, though horrified, keeps his promise and has Jochanaan beheaded. Salome kisses the head of the prophet, an act that audiences of the early 1900's considered especially objectionable.

Scene from a production by the Metropolitan Opera Association, with Birgit Nilsson; Frank Dunand, the Metropolitan Opera Guild

Salome by Richard Strauss is a passionate and violent opera that takes place in Palestine at the time of Christ. In the one-act opera's best-known scene, *above,* Salome performs the "Dance of the Seven Veils" before King Herod and his court.

Strauss's score captures perfectly the mood of Wilde's gruesome story. The music is often violent and harsh. At other times, it is vigorous and passionate. The orchestral music especially helps create the rich Oriental atmosphere of the opera. The role of Salome is one of the most difficult in the repertoire. The performer must not only sing extremely complicated music, but she must also act and dance well. In addition, she should look young and beautiful.

Tosca, a tragic opera in three acts by Giacomo Puccini. Libretto in Italian by Giuseppe Giacosa and Luigi Illica, based on the French play *La Tosca* by Victorien Sardou. First performed in Rome in 1900.

The story of *Tosca* takes place in Rome in 1800, when the city is torn by political intrigue. The chief characters are Floria Tosca, a famous singer; Mario, a painter and Tosca's lover; and Baron Scarpia, the villainous chief of police. In the story, Cesare Angelotti, an escaped political prisoner, has fled from Scarpia. Both Tosca and Mario know Angelotti's hiding place. Much of the action concerns Scarpia's attempts to force Tosca and Mario to reveal where Angelotti is hiding. Scarpia also wants to make Tosca his mistress. Tosca kills Scarpia and then commits suicide after she watches a firing squad execute Mario.

Puccini's music powerfully expresses the passion and violence of the plot. The work also has several beautiful melodies, including Tosca's "Vissi d' arte" in Act II and Mario's "E lucevan le stelle" in Act III.

Traviata, La (*The Wayward One*), a tragic opera in three acts by Giuseppe Verdi. Libretto in Italian by Francesco Maria Piave, based on the French play *The*

Scene from a production by the Santa Fe (N. Mex.) Opera, with George Shirley and Maralin Niska; Santa Fe Opera

La Traviata by Giuseppe Verdi describes a tragic love affair between Alfredo and Violetta in France during the mid-1800's. In this scene from Act I, they meet for the first time at a party.

Lady of the Camellias by Alexandre Dumas the Younger. First performed in Venice, Italy, in 1853.

Although *La Traviata* failed dismally at its première, it has become one of the most frequently performed works in the repertoire. Verdi set the action in and near Paris in the mid-1800's. The opera shocked many people during the mid-1800's because Violetta, its heroine, leads an immoral life.

Unlike many earlier operas, *La Traviata* has realistic characters with complicated emotions. Their thoughts and feelings seem especially convincing because of Verdi's theatrically effective music. For example, in Act I, Violetta tries to decide whether to fall in love with Alfredo, who loves her. The music clearly reflects her indecision. In Act III, she sings one of the opera's most haunting arias, "Addio del passato," in which she bids farewell to the happy days of the past.

Trovatore, Il (*The Troubadour*), a tragic opera in four acts by Giuseppe Verdi. Libretto in Italian by Salvatore Cammarano, based on the Spanish play *El Trovador* by Antonio García Gutiérrez. First performed in Rome in 1853.

Like most Verdi operas, *Il Trovatore* tells a gloomy and violent story filled with passion. The action takes place in Spain in the 1400's. The principal characters include Manrico, a *troubadour* (poet-musician); Leonora, a noblewoman; Azucena, a Gypsy; and the Count di Luna. Manrico and Leonora are lovers, but the count also loves Leonora. In addition, di Luna and Manrico are brothers, though only Azucena knows it. Azucena seeks revenge against the count because his father had her mother burned at the stake. By the opera's end, Leonora has committed suicide and the count has executed Manrico. After Manrico's death, Azucena tells the count he has killed his brother, and she thus has her revenge.

Despite a frequently confusing plot, *Il Trovatore* is brilliantly effective theater. The opera also has some of Verdi's most memorable music. In Act II, a band of Gypsies in their mountain camp sings what is perhaps the most familiar choral number in all opera, the stirring "Anvil Chorus."

Wozzeck, a tragic opera in three acts by Alban Berg. Libretto in German by the composer, based on the German play *Woyzeck* by Georg Büchner. First performed in Berlin in 1925.

Wozzeck is a private in the Austrian army about 1830. His superiors abuse and ridicule him. Even worse, Marie, the woman he loves, deceives him with another man. Driven almost insane by jealousy, Wozzeck stabs and kills Marie. Later, he throws the knife into a pond. Finally, he drowns while searching for the knife.

Much of the text for *Wozzeck* is set in an intensely emotional vocal style midway between spoken dialogue and singing. This style is known by the German term *Sprechstimme* (speaking voice). Most of the music is atonal—that is, it does not fall into the traditional keys.

Although *Wozzeck* is difficult to sing and play, it has been performed in many countries. Some people consider the music jarring and too hard to understand. But others feel that it effectively expresses a great variety of emotions. Thomas Bauman

Operation. See Surgery.

Operation Desert Storm. See Persian Gulf War.

Operetta is a type of musical theater that achieved its greatest popularity from the 1850's to about 1920. Unlike a typical serious opera, operetta contains spoken dialogue instead of sung dialogue and fairly simple, straight-forward songs instead of complex arias. An operetta overture is often a medley of tunes from the show rather than a separate composition, as in opera.

Operettas generally are composed in an uncomplicated and popular style. The music is easy to perform and to understand. The plots of most operettas are romantic, sentimental, or satirical. They often involve confusion over mistaken identities and have happy endings, frequently with a moral. Most operettas also feature dances and choruses.

Operettas developed from French comic opera. Several national schools of operetta developed, beginning with the French school. The first masterpieces in the form were written by Jacques Offenbach, a German-born French composer. His major works include *Orpheus in the Underworld* (1858), *La Belle Hélène* (1864), and *La Périchole* (1868).

The Austrian composer Franz von Suppé was the first composer of Viennese-style operettas, beginning in the 1860's. This musical style is based on dance forms, especially the waltz. The settings are also more exotic than those of French operettas.

The master of the Viennese school was Johann Strauss, Jr. His operetta *Die Fledermaus* (1874) is the greatest example of the school. Romantic Viennese operettas dominated the form in the early 1900's with such works as *The Merry Widow* (1905) by Franz Lehar.

English composers were greatly influenced by both French and Viennese operetta. By the 1870's, the team of Sir William Gilbert and Sir Arthur Sullivan had developed an English style in such humorous and satirical works as *H.M.S. Pinafore* (1878) and *The Mikado* (1885).

Operettas were extremely popular in the United States, with French, Viennese, and English works receiving numerous productions. By the 1890's, American composers began writing successful operettas. The principal composers included Reginald de Koven, Rudolf Friml, Victor Herbert, Sigmund Romberg, and John Philip Sousa. Katherine K. Preston

Ophthalmia, *ahf THAL mee uh,* is a name for severe diseases affecting the eye membranes. These diseases may be caused by infections, poisons, or injuries. For example, *ophthalmia neonatorum* is an infection of the eyes of newborn babies, usually caused by the germ that causes gonorrhea. *Sympathetic ophthalmia,* a rare condition, spreads to both eyes after a serious injury to one eye and can lead to blindness if untreated. See also **Blindness** (Diseases). Ronald Klein

Ophthalmology, *AHF thal MAHL uh jee,* is the field of medicine involving the diagnosis and treatment of eye diseases. An *ophthalmologist* must have an M.D. degree and three to five years of specialized training in a residency program, usually in a hospital.

Most ophthalmologists limit their medical and surgical practice to the eye. They examine the eye with special equipment and check *visual acuity* (the ability of the eye to see). If a patient's visual acuity is less than normal, an ophthalmologist usually does a *refraction* to determine whether the decrease in vision can be corrected with glasses. A refraction is a check of the power of the lens and cornea of the eye relative to the size of the eye. If the patient needs glasses, the ophthalmologist usually gives the patient a prescription for them. Glasses are made by an *optician.*

If the patient's vision cannot be corrected with glasses, the ophthalmologist's examination will help detect the cause of poor vision. An ophthalmologist performs the necessary operation if an eye condition requires corrective surgery, such as the removal of *cataracts* (clouding of the lens of an eye). Ophthalmologists also may perform other types of surgery, including surgery to correct *strabismus* (cross-eye) or other muscle imbalances of the eyes, corneal transplants, and surgery to control *glaucoma* (increase in fluid pressure in the eye).

By studying the *retina* (back layer of the eye), an ophthalmologist may discover signs of diseases of other parts of the body. For example, such diseases as diabetes, AIDS, and certain forms of anemia may cause changes in the appearance of the retina. Ronald Klein

See also **Optometry; Surgery** (Surgical specialties).

Ophthalmoscope, *ahf THAL muh skohp,* is an optical instrument for examining the interior of the eye. Ophthalmologists and optometrists can make certain diagnoses by using the ophthalmoscope to examine abnormalities in the eye.

There are two types of ophthalmoscopes, the *direct ophthalmoscope* and the *indirect ophthalmoscope.* The direct ophthalmoscope contains a light, a prism and a mirror, and lenses. These parts are mounted in the head of the instrument, which is attached to a handle containing a battery. The prism and mirror project the light on the back of the eye. The lenses enable the examiner to focus the light to provide a clear, magnified view of the eye's interior. The indirect ophthalmoscope consists of a light worn on the examiner's head and a lens held in front of the patient's eye. This instrument enables the examiner to see a larger area than the direct ophthalmoscope does, but with lower magnification.

WORLD BOOK photo by Dan Miller

An ophthalmoscope is used to examine the interior of the eye. The examiner peers through a tiny hole in the ophthalmoscope while focusing light into the patient's eye.

The ophthalmoscope was invented by a German physicist, Hermann von Helmholtz, in 1851 (see **Helmholtz, Hermann L.**). Helmholtz' instrument consisted of a sandwich of three thin plates of glass mounted at a 45-degree angle on a handle. A light was placed to the side of the eye under examination. Some light passed through the glass plates, but some was reflected into the eye. The lighted inside of the eye was observed through the glass. Ronald Klein

Opiate, *OH pee iht,* is any drug made from or containing opium. Opium is a dried milky substance obtained from unripened seedcases of the opium poppy plant. Morphine and codeine are opiates used for their healing properties. These drugs are *analgesics* (painkillers). Physicians prescribe them mainly for people with severe pain. Opiates also are used to help control coughing and severe diarrhea.

Continued use of opiates can reduce their healing effects and can also lead to addiction. Therefore, opiates and synthetic drugs that have the same chemical structure as opiates have been made *controlled substances* by law. This means they can be obtained lawfully only

by getting a prescription from a physician or, in some cases, by signing a register at a pharmacy. Heroin is a highly addictive opiate. Federal law totally prohibits the sale and use of heroin in the United States.

Barbara M. Bayer

Opinion poll. See Public opinion poll.

Opium is a drug that serves as the source of several medicines, including codeine and morphine. Heroin, an illegal drug, is also made from opium. Opium and most *opiates* (drugs made from or containing opium) can cause addiction. The United States and many other nations restrict their manufacture, distribution, and use.

Opium is made from the juice of the opium poppy. Most opium used by U.S. drug manufacturers comes from poppies grown on farms in India. Processors near the poppy farms make dried poppy juice, called *raw opium,* into a brownish powder known as *refined opium.* They also extract a yellowish powder called *morphine base* from the opium. Drug manufacturers use refined opium and morphine base to make codeine, morphine, and other medicines.

Heroin and most other illegal opiates are made from morphine base. Most illegal opiates are made in France, Latin America, the Middle East, and Southeast Asia.

Medical uses. Opium ranked as the most effective pain-relieving drug until the development of morphine in the early 1800's. Opium was also used to stop coughing and diarrhea, to ease worry, and to cause drowsiness. Opiates serve many of the same purposes today. Physicians prescribe morphine to relieve severe pain. Codeine, probably the most widely used opiate, stops coughing. The opiate paregoric controls diarrhea.

Opium addiction. The misuse of opium or of drugs made from it can lead to addiction. Opium, when first used, can give users a feeling of extreme calm and well-being. Their troubles may seem unimportant, and they temporarily live in an unreal world of isolated contentment. People smoke, sniff, or eat opium for these effects. But an addict may have vivid dreams and daydreams that may be extremely unpleasant. Opium addicts tend to neglect their health and their families.

WORLD BOOK illustration by Robert Hynes

The opium poppy is a plant used to produce opium, a drug that is the source of heroin and several medicines.

Addicts who want to stop taking opiates can obtain medical treatment and counseling. Some experimental programs use a drug called *methadone* to help patients overcome addiction to opiates (see Methadone).

History. The use of opium began at least 6,000 years ago in the Middle East. Greek and Roman physicians prescribed the drug before the time of Christ. Arabian traders took opium to China and India, probably starting in the A.D. 600's. At first, the Chinese used the drug chiefly as a medicine. European traders introduced opium smoking into China in the early 1600's. The Chinese government outlawed opium in 1729, but traders continued to exchange it for silk, porcelain, and other Chinese products. In the late 1700's, opium addiction became widespread among the Chinese. The opium trade helped cause the so-called Opium War (1839-1842), in which England defeated China (see **China** [Clash with the Western powers]).

During the 1800's, people in the United States and Europe could buy laudanum, morphine, and other opiates legally and without a prescription. By 1900, at least 200,000 Americans had become addicted to opiates. The Harrison Act, a group of laws passed in 1914, greatly reduced the problem in the United States. Addiction to opiates, particularly heroin, began to increase in the late 1940's and has continued to rise ever since. Today, a number of nations and international organizations cooperate in fighting the illegal manufacture and sale of opium and opiates. Donald J. Wolk

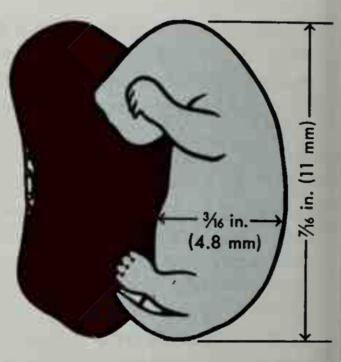
Opossum, *uh PAHS uhm,* is any member of a family of furry mammals that live in the Western Hemisphere. The female opossum carries its young in a pouch on its abdomen. Opossums, kangaroos, and other mammals that give birth to extremely undeveloped young are called *marsupials.* Opossums are the only marsupials that are native to North America. They live from Ontario in Canada southward into South America.

There are many species of opossums, most of which live in Central and South America. Small, tree-dwelling *murine opossums* resemble mice. *Woolly opossums* have thick, soft fur. Another kind of opossum, the *yapok,* is the only marsupial that is adapted for living in water. Its webbed feet help make it a good swimmer.



The *common opossum* is the only kind of opossum found in the United States. This species grows about as big as a house cat. It has rough grayish-white hair, a long snout, dark eyes, and big hairless ears. This opossum has a long tail that does not have much hair on it. The animal can hang upside down by wrapping its tail around a tree branch. This opossum has 50 teeth, more than any other North American mammal. Its teeth and claws are sharp. Opossum tracks are easy to recognize because the animal has long, widely separated toes.

Opossums are born in groups of from 5 to 20. At birth, an opossum is only about as big as a kidney bean. The female opossum carries its tiny babies in a pouch on the outer skin of its abdomen for about two months

E. R. Degginger

A mother opossum carries its young on its back. Baby opossums stay in their mother's pouch for about two months after birth. They remain near her for several more weeks.

A newborn opossum is about the same size as a kidney bean.

after birth. After leaving the pouch, the young stay near the mother for several more weeks. When they can take care of themselves, the young go off on their own.

Opossums hunt at night. They eat almost any kind of animal or vegetable food. When in danger, opossums sometimes "faint" and appear to be dead.

Frank B. Golley

Scientific classification. Opossums make up the opossum family, Didelphidae. The scientific name for the common opossum is *Didelphis marsupialis.*

Oppenheimer, *AHP uhn HY muhr,* **J. Robert** (1904-1967), an American physicist, became known as the father of the atomic bomb. From 1943 to 1945, he directed the laboratory at Los Alamos, N. Mex., where the design and building of the first atomic bomb took place.

From 1947 to 1952, Oppenheimer headed the advisory committee of the newly formed United States Atomic Energy Commission (AEC). He also advised the U.S. Department of Defense and helped write the first United States proposal for international control of nuclear energy.

In 1953, Oppenheimer's loyalty to the United States was questioned. The charges of disloyalty gave rise to probably the most famous security hearing of the 1950's. Oppenheimer's opposition to the development of the hydrogen bomb, together with his past associations with Communists, led to an investigation in 1954 by an AEC security panel. The panel cleared Oppenheimer of all charges of disloyalty, but it denied him further access to secret information. In 1963, the AEC gave Oppenheimer its highest honor, the Enrico Fermi Award, for his contributions to theoretical physics. Many people viewed this as an effort by the government to correct a tragic mistake.

Oppenheimer was born in New York City. He graduated from Harvard University in 1925 after three years of study. In 1927, Oppenheimer received a doctor's degree from the University of Göttingen in Germany. From 1929 to 1947, Oppenheimer was on the faculty of the University of California at Berkeley, where he established a leading center for research in theoretical physics. During that time, he also taught part of each year at the California Institute of Technology. Oppenheimer served as director of the Institute for Advanced Study in Princeton, N.J., from 1947 to 1966.

Roger H. Stuewer

Opposition is a term that describes the relative position of two heavenly bodies when the earth comes closest to being directly between them. At full moon, for example, the moon is in opposition to the sun. The term is most commonly used to describe positions with respect to the sun. When a *superior planet*—that is, one whose distance from the sun is greater than the earth's—is on the opposite side of the earth from the sun, it is said to be in opposition. For example, the planet Mars is in opposition when the earth is directly between Mars and the sun.

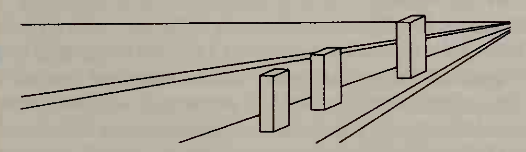
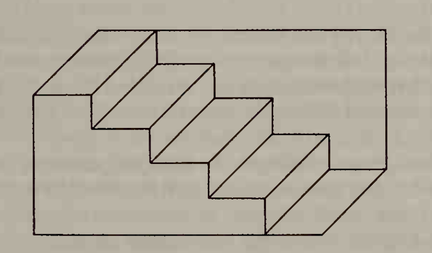
Optical fiber. See **Fiber optics.**



Optical illusion. As we look down a long, straight road, we see that it seems to grow narrower in the distance. Trees and telegraph poles along the road appear to grow smaller as they stretch away toward the horizon. We know that a white house looks larger than the same house painted a dark color, and that a man wearing a suit with up-and-down stripes looks thinner than he would if the stripes went crosswise. We call appearances of this kind *optical illusions* because we know that in such cases things are not the way they appear to be.

Optical illusions of the kind described above are called "normal" illusions, because every person with normal eyesight experiences them. But an optical illusion does not occur every time we are deceived by what we see. Often we make mistakes in interpreting the impressions our eye receives. For example, many persons will read the sentence "he walked though the busy street," and never notice that the third word has no "r" in it. They *expect* to see "through" and therefore they *do*



Some common optical illusions

Lines A-B and B-C in the above figure are equal in length. However, line B-C appears to be longer because of the angles of the other lines in the figure.

These blocks are all the same size, but the ones drawn to appear farther from the viewer seem larger. This illusion occurs because the blocks are not drawn in perspective.

This staircase has stairs that run up from right to left. But the figure can also be seen as an upside-down staircase, with the stairs running "up" from left to right.

see "through." Such mistaken impressions are not optical illusions. David E. Eifrig

Optics is the branch of physics and engineering that is concerned with the properties of light. It describes how light is produced, how it is transmitted, and how it can be detected, measured, and used. Optics includes the study of visible light and of infrared and ultraviolet rays, both of which are invisible.

Many instruments, including binoculars, cameras, magnifiers, microscopes, projectors, and telescopes, operate according to the principles of optics. All these instruments have optical devices, such as lenses and mirrors, which transmit and control light. Light is detected and measured with instruments called *light meters* (see **Light meter**).

Scientists have used the principles of optics to increase the number of ways to use light. For example, they can transmit light along a twisted or curved path by sending the light through a filament called an *optical fiber.* Scientists use a device called a *laser* as an important and powerful light source (see **Laser**).

There are three major branches of optics. *Physical optics* deals with the nature and behavior of light as a wave. *Geometrical optics* is concerned with optical instruments and what happens when light strikes them. *Quantum optics* studies the nature of light as individual particles, known as *photons.*

Basic principles of optics describe what light is and how it behaves. To study visible light, scientists use a *prism* (wedge of glass) that produces a band of colors called the *visible spectrum.* Scientists analyze this and other spectra with an instrument called a *spectroscope.* See **Light** (Electromagnetic waves); **Spectrometer**.

A number of different reactions may occur when light strikes the surface of an object. Diffraction, interference, reflection, and refraction are some of the basic principles that describe what may happen. Other principles include the chemical effects of light, dispersion, the photoelectric effect, and polarization. See **Light** (How light behaves).

History. The development of optics began chiefly during the 1600's. The Italian scientist Galileo built telescopes to observe the planets and the stars. Sir Isaac Newton, an English scientist, experimented with lenses and used a prism to break sunlight into its colors (see **Newton, Sir Isaac** [Light and color]). In Holland, the physicist Christiaan Huygens studied polarization and proposed a wave theory of light.

During the early 1800's, two physicists, Thomas Young of England and Augustin Fresnel of France, did much to confirm Huygens' theory. Young formulated the principle of the interference of light. Fresnel then developed a mathematical formula that supported this principle. Most scientists accepted the work of Young and Fresnel as proof of Huygens' theory.

During the mid-1800's, accurate measurements of the speed of light were made by the French scientists Armand H. L. Fizeau and Jean B. L. Foucault. At about the same time, two German scientists, Robert Bunsen and Gustav Kirchhoff, showed that atoms of chemical elements produced the color bands of the spectrum. In 1864, the British physicist James C. Maxwell introduced the electromagnetic theory of light.

Scientists made several important discoveries in optics during the late 1800's and the 1900's. Such scientists as Albert A. Michelson of the United States, Frits Zernike of the Netherlands, and Dennis Gabor of England received the Nobel Prize for physics for their work in optics. Brian J. Thompson

Optimist International is an association of service clubs in the United States, Canada, and the Caribbean. Membership is by invitation to business and professional people of the local community. Optimist Clubs work to develop optimism as a philosophy of life. They promote good government, respect for law, patriotism, friendship among all people, and service to youth.

Under the motto "Friend of Youth," Optimist Clubs conduct a wide range of service projects for young people. Through their Just Say No program, Optimists provide information and peer support to help children resist the temptation to become involved with drugs. The clubs sponsor an annual essay contest and public speaking contest for young people of high school age. Win-

ners of each contest receive college scholarships. Other programs for young people include Bike Safety Week, Youth Appreciation Week, and an international golf tournament called the Optimist Junior World Championships.

Eleven Optimist Clubs founded Optimist International in Louisville, Kentucky, in 1919. The organization now has about 173,000 members in 4,200 Optimist Clubs. Headquarters of the organization are in St. Louis, Missouri. Critically reviewed by Optimist International

Optometry, *ahp TAHM uh tree,* is a profession devoted to the care of vision. Optometrists give eye health and vision examinations. They diagnose vision problems that affect a person's ability to see nearby and distant objects clearly and to judge distance. They also test the ability of the eyes to work together and to change focus easily. Optometrists prescribe eyeglasses and contact lenses to correct faulty vision. In the United States, optometrists can perform minor procedures such as removing foreign objects from the eye. They can treat some forms of glaucoma and other eye diseases with drugs. They also may recommend vision therapy to help a person overcome certain vision problems.

To practice optometry in the United States or Canada, a person must pass an examination for a state or provincial license. Optometrists in the United States must have completed two or three years of preoptometry college work and graduated from a four-year school or college of optometry. Most optometry students have undergraduate degrees before entering the professional degree program. All schools and colleges of optometry award the Doctor of Optometry (O.D.) degree. Canada has similar requirements. Additional information may be obtained from the American Optometric Association in St. Louis, Missouri.

Oracle, *AWR uh kuhl,* in the ancient Greek world, was a shrine where people came to seek advice from prophets or prophetesses. They were individuals who had special powers to speak on behalf of a god. These sacred persons were believed to have the power to reveal the will of the gods and to foretell the future. The word *oracle* also refers to the prophet and prophetess, and to their prophecy.

The most important oracle was in Delphi in central Greece, and was dedicated to the god Apollo. The prophetess of Delphi, often called the Pythia, sat on a large three-legged stand or tripod. In a state of ecstasy inspired by Apollo, she frequently uttered his oracles in a strange and puzzling form. The meaning of the Pythia's oracles was often so unclear that priests at the shrine interpreted them for the public.

Most oracles were dedicated to Apollo. Some were dedicated to Zeus or other gods. One famous oracle of Zeus was in a grove of oak trees in Dodona in northwestern Greece. The people believed that Zeus spoke through the rustling of the oak leaves. The priests at Dodona interpreted these rustlings. Other important oracles were in Italy, Libya, and Syria. John Hamilton

Oran, *oh RAN* or *aw RAHN* (pop. 1,110,000), is a Mediterranean seaport in Algeria. It lies about 225 miles (362 kilometers) west of Algiers. For location, see **Algeria** (map).

Oran trades with cities of inland Africa and ports of southern Europe. It was founded by Muslim sailors from Spain in the A.D. 900's. The city was captured by the Spaniards in 1509, by the Turks in 1708, and again by the Spaniards in 1732. Spain abandoned Oran after much of it was destroyed in 1791 by an earthquake. The Santa Cruz fort, built by the Spaniards between 1698 and 1708, still overlooks the city from a nearby hill. In 1831, the French occupied Oran. During World War II (1939-1945), Allied forces landed near Oran as part of the campaign to drive the Axis powers from North Africa.

Kenneth J. Perkins

Orange. See **Color.**

Orange is a popular citrus fruit enjoyed by people throughout the world. Oranges are valued for their delicious juice and high vitamin C content. They are an excellent source of potassium and also contain thiamine and folic acid.

About 65 million tons (60 million metric tons) of oranges are harvested throughout the world each year. Brazil is the leading orange-producing nation in the world.

In the United States, over 11 million tons (10 million metric tons) of oranges are harvested yearly—more than any other fruit. Florida produces about 70 percent of the U.S. crop, and California grows most of the rest. Arizona and Texas also produce oranges.

About three-fourths of the oranges grown in the United States are processed into frozen concentrated or fresh juice. Small amounts of oranges are used for making baked goods, candy, marmalade, salads, and soft drinks. Most of the remaining orange crop is sold as fresh fruit. The orange peel, pulp, and *rag* (core) are used primarily as cattle feed supplements.

There are several types of oranges, the most popular of which is the sweet orange. Oranges vary in shape from round to oval, and the peel ranges from pink to orange to dark red in color. They grow best in regions with warm summers and cool winters in which the temperatures do not go below freezing. Freezing temperatures can severely damage the tree and the fruit.

The fruit and the tree

The orange is a type of berry called a *hesperidium.* The peel consists of a colored outer layer called the *flavedo* and a white, spongy inner layer known as the *albedo.* The flavedo contains tiny glands that contain a mixture of aromatic oils. The edible interior of the orange consists of 10 to 15 segments, which surround a spongy core. The segments contain many *juice sacs,* which hold the juice and make up the pulp of the orange. The segments of some varieties of oranges also contain seeds. Other varieties of oranges are seedless or nearly seedless.

The orange tree has dark green leaves and beautiful, white, fragrant flowers. Fruits develop from the ovaries of the flowers. Some varieties of oranges may be harvested within 7 months after the flowers bloom, but others may remain on the tree up to 16 months. Growers plant different varieties of oranges in the same area so

that mature fruit is available during most or all of the year.

Orange trees develop new branches during periods of rapid growth called *growth flushes.* During these growth flushes, new stems, leaves, and, often, blossoms appear on the trees and some of the flowers develop into fruit. The number and timing of growth flushes that occur each year vary according to the climate. In climates like those of Florida and California, growth flushes do not occur during the winter. Instead, a period of vigorous growth takes place in the spring, during which many flowers appear on the trees and a large number of fruits develop.

Varieties

The word *orange* commonly refers to three types of citrus fruit: (1) sweet oranges, (2) sour or bitter oranges, and (3) mandarins.

Sweet oranges. Growers around the world raise more sweet oranges than any other type of citrus fruit. These oranges have a sweet flavor and are round to oval in shape. There are four groups of sweet oranges: (1) common or round oranges, (2) navel oranges, (3) blood oranges, and (4) acidless oranges.

Common oranges are the most important type of sweet orange. Most oranges sold as fresh fruit are common oranges. In addition, almost all orange juice is made from common oranges. Juice from the Valencia orange, a type of common orange, makes the highest quality juice products. The Valencia is the most popular variety of orange in the world.

Navel oranges have a small secondary fruit growing at one end of the main fruit. They are seedless and have a pleasant flavor, but they produce less juice than do common oranges. California produces most of the U.S. navel-orange crop.

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd.

Oranges are popular citrus fruits that contain delicious juice and large amounts of vitamin C. In the United States, more oranges are harvested yearly than any other type of fruit.

Blood oranges have an unusual color, but in other ways are similar to common oranges. The flesh and peel of blood oranges range in color from pink to red. The oranges only become red in climates with cool night temperatures. Blood oranges are widely grown in Mediterranean countries. Few are planted in other areas of the world.

Acidless oranges have a low level of acid in their juice and consequently have a bland flavor. Acidless oranges have very little commercial value except in Brazil.

Sour or bitter oranges generally are not eaten fresh because the flesh has a bitter taste. Sour oranges are grown mainly in Europe and are widely used in making marmalade. Oils from the peel of some sour oranges and ingredients from the leaves and flowers are used in manufacturing perfume.

Mandarins are a group of fruits that includes true mandarins, tangerines, and various hybrids, such as tangelos and tangors. Mandarins are not really oranges, but they are often referred to as such because of their orange color. Mandarins taste sweet and are generally eaten fresh. Their peel separates easily from their edible interior. See **Tangelo; Tangerine; Tangor.**

Raising oranges

Planting and caring for orange trees. Most orange trees are grown from buds in special nurseries. A small piece of stem containing a bud is cut from a tree that produces the variety of orange desired. The stem is then grafted to a seedling orange tree called a *rootstock* (see **Grafting** [Other kinds of grafting]). Rootstock varieties are selected for their ability to produce high-yielding trees, adapt to the local soil and climate, and resist pests and disease. Orange trees are transplanted in groves 6 to 12 months after grafting. They start to bear fruit 2 to 4 years later and may produce oranges for 50 years.

Pests and diseases. Orange trees may be attacked by many pests and diseases. Scale insects suck the sap from the fruit, leaves, and twigs. Certain wasps kill these insects, so growers foster the growth of these wasps in the orange groves. Two other sucking pests, rust mites and aphids, also damage the leaves. These pests are killed by spraying the trees with pesticides. Nematodes and weevils may attack orange roots.

Virus diseases weaken or kill orange trees. The virus disease tristeza is especially deadly. Growers fight these diseases by planting virus-free trees that can naturally resist or tolerate the viruses. Such fungal diseases as melanose and greasy spot also cause extensive damage. Melanose produces tiny, raised dots on the stems, leaves, and fruit. Greasy spot causes oily-looking blotches on the leaves. Growers control fungal diseases by spraying the trees with fungicides.

Harvesting and processing. As oranges mature, the amount of sugar and juice they contain increases and their acid content decreases. In the United States, state and federal laws determine the levels of sugar, juice, and acid that oranges must contain to be considered mature. Oranges and other citrus fruit differ from most other fruit in that they do not mature further after they have been harvested. For this reason, growers pick the

Florida Division of Tourism

Harvesting oranges that are to be sold as fresh fruit involves clipping the ripe fruit by hand. If the oranges are pulled from the trees roughly, they may be damaged.

U.S. Department of Agriculture

At a packing house, shown here, oranges that are to be sold as fresh fruit are sorted according to grade and size. They are then packed in boxes for shipment to markets.

oranges only when the fruit contains the required levels of juice, sugar, and acid.

If oranges are pulled from the trees roughly, they may be bruised or damaged, especially at the point where the stem joins the fruit. These damaged fruit may be easily attacked by fungus diseases that cause decay. For this reason, oranges that are to be sold as fresh fruit are either clipped or carefully harvested from the trees by hand. They are then transported to packing houses in large bins that hold about 900 pounds of oranges (400 kilograms). These oranges are then washed and dried. Next, they are waxed with a special coating that prevents dehydration and improves their appearance. The oranges are then graded, sized, packed into boxes, and shipped to markets. Some mature oranges have a partly green peel and may be treated with ethylene gas to reduce the green color of the peel.

Oranges that are to be sold for processing are usually transported in bulk by truck. If they are processed within a few days after harvesting, no serious fruit losses are suffered from bruising or decay. The juice is extracted from the fruit by machine and is then heat-treated to kill harmful bacteria, yeast, and mold, and to inactivate enzymes.

History

Oranges are among the oldest cultivated fruits. People have grown oranges for more than 4,000 years. Oranges probably originated in the part of Asia that now includes India, Myanmar, and southwestern China. By the A.D. 800's, Arab traders had introduced oranges into eastern Africa and the Middle East. In the 1400's, Portuguese travelers carried oranges from India to Europe. The Italian explorer Christopher Columbus brought orange seeds to America in 1493. During the 1500's, Euro-

Leading orange-growing countries

Tons of oranges produced in a year

Country	Production
Brazil	24,065,000 tons (21,831,000 metric tons)
United States	11,710,000 tons (10,623,000 metric tons)
Mexico	4,347,000 tons (3,943,000 metric tons)
China	3,797,000 tons (3,445,000 metric tons)
India	3,307,000 tons (3,000,000 metric tons)
Spain	3,005,000 tons (2,726,000 metric tons)
Italy	2,304,000 tons (2,090,000 metric tons)
Iran	1,898,000 tons (1,722,000 metric tons)
Egypt	1,807,000 tons (1,639,000 metric tons)
Pakistan	1,315,000 tons (1,193,000 metric tons)

Figures are for a three-year average, 1999-2001.

pean settlers planted orange trees in Florida and Brazil. The first orange groves in California were established by Spanish missionaries in the late 1700's. The major varieties of oranges grown today were selected during the 1800's. Several new varieties were developed in the late 1900's by crossbreeding oranges with grapefruit or tangerines.

The U.S. orange industry has grown rapidly since the early 1900's. At that time, oranges were rare and expensive, and many people ate them only as a treat on holidays. Today, because of improved growing methods and other factors, most people in the United States can afford oranges and orange juice throughout the year.

Wilfred F. Wardowski

Scientific classification. Oranges are members of the rue family, Rutaceae. Sweet oranges belong to the species *Citrus sinensis.* Sour oranges are classified as *Citrus aurantium.* Mandarins are the fruits of several species and their hybrids. True mandarins belong to the species *Citrus reticulata.*

Orange Free State is a historic region in South Africa. Before Europeans conquered the area in the 1830's, most of its inhabitants were people of the Sotho group of black Africans. About 1836, Boers from Cape Colony settled the region. The Boers named the area the Orange Free State in 1854.

In 1899, disagreements between the Boers and the British led to the Boer War (1899-1902). The Boers were defeated. In 1910, the Orange Free State became one of the four provinces of the Union of South Africa (now the Republic of South Africa). In 1994, South Africa increased the number of its provinces to nine. The Orange Free State remained a province, but the province's name was changed to the Free State in 1995.

The Free State covers 49,866 square miles (129,152 square kilometers). Black Africans make up a large majority of the province's population, but white people own nearly all the land. Most of the black Africans work for white farmers or in gold and uranium mines in the northern part of the province. Bloemfontein is the capital of the Free State and the judicial capital of South Africa. Bruce Fetter

Orange Order is a Protestant organization in Northern Ireland. It seeks to keep Protestants in power in the country and to maintain Northern Ireland's union with Britain. The Orange Order was founded in 1795 by Anglican Protestant farmers in County Armagh, Ireland, in what is now the southern part of Northern Ireland. It grew out of a conflict between Protestant and Roman Catholic farmers who were bidding to become tenants on the same farmlands. The Protestant farmers joined together to drive Catholic families out of the region.

The organization was named for William of Orange. William was the Protestant leader of the Netherlands who, in 1689, overthrew James II, the Catholic king of England, Scotland, and Ireland.

The Orange Order of Northern Ireland is organized into units called *lodges.* It has about 1,500 lodges and about 100,000 members. The members, called *Orangemen,* parade through Protestant and Catholic neighborhoods during the "marching season" of July. They sing and carry banners to celebrate past Protestant victories over Catholics. Paul E. Gallis

Orange River is the longest river in South Africa. It flows westward across the southern part of the African continent. Sandbars and shallow waters make the Orange River useless for navigation. However, the river serves as an important source of hydroelectric power and provides much-needed water for irrigation projects. In some areas, the gravel of the river contains diamond deposits. For the location of the Orange River, see **South Africa** (terrain map).

The Orange River rises in the mountains of Lesotho and flows into South Africa. It winds west and northwest for about 1,300 miles (2,100 kilometers). It empties into the South Atlantic Ocean at Alexander Bay. The upper river separates Northern Cape and Eastern Cape provinces from the Free State province. The river then flows across the plateaus of central South Africa to the town of Prieska. From Prieska to the Augrabies Falls, the elevation of the river drops steadily. The lower course of the river stretches from the Augrabies Falls to the western coast, flowing through rugged desert country. The lower section separates Northern Cape Province and Namibia.

Much of the Orange River is narrow, with deep gorges. A large sand bar blocks the mouth of the river and prevents passage by seagoing ships. The river has two major branches, the Vaal and Caledon rivers.

The Orange River was named in honor of the Dutch Prince of Orange in the late 1700's. Robert J. Gordon, a Dutch military commander in South Africa, chose the name. Africans who lived in the area had called the river the Gariep. During the 1860's, diamonds were discovered along the river's course. In 1962, the South African government announced a development plan for the Orange River. Since then, the government has built dams on the river to provide hydroelectric power. It has also built canals and tunnels to irrigate nearby land and to provide flood control. Hartmut S. Walter

Orange roughy. See **Roughy.**

Orangutan, *oh RANG u tan,* is a large, red-haired ape that lives in the tropical rain forests on the islands of Borneo and Sumatra in Southeast Asia. Orangutans are the largest tree-dwelling mammal. A male orangutan stands about 4 $\frac{1}{2}$ feet (140 centimeters) tall and weighs about 180 pounds (80 kilograms). Mature males have broad cheek pads that jut out from the sides of their face and a large throat pouch. Females are about half as large as males. They have no cheek pads and only small throat pouches.

An orangutan's arms are extremely long compared to its legs and upper body, reaching to its ankles when the animal stands erect. Orangutans also have long, curved fingers and toes that help them grasp branches, making them well-suited for life in trees. They eat and sleep high in the treetops and rarely come to the ground.

Orangutans feed mainly on figs and other fruit. They also eat leaves, bark, and occasionally insects. Orangutans build nests of woven branches for resting and sleeping. They make and use simple "tools" such as sticks that they have stripped of leaves.

Orangutans are less social than other apes. Adults live far apart in the forest and usually avoid one another. Males and females spend several days together when they mate but then part. Females and their young occupy an area called a *home range.* Strong, mature males have a large home range that includes the ranges of

several females. Younger males may roam the forest. If two males meet in the presence of a female, they may fight. Orangutans once lived throughout southern China and Southeast Asia. Today, they are an endangered species. The chief causes of their endangerment include destruction of their habitat, hunting, and the collection of animals for zoos. Laws protect the remaining orangutans and preserve their habitat.

Scientific classification. Orangutans belong to the great ape family, Pongidae. The scientific name for the Bornean orangutan is *Pongo pygmaeus pygmaeus.* The Sumatran orangutan is *Pongo pygmaeus abelli.* Randall L. Susman

See also **Ape.**

Oratorio is a dramatic vocal composition usually based on a religious story. Oratorios resemble operas. Both tell a story and are performed by solo singers, a chorus, and an orchestra. The main difference is that oratorios have no acting, costumes, or scenery. Most oratorios are presented in concert halls or in churches.

In oratorios, soloists often portray specific characters, and the chorus usually is an important element. Although there is no acting or scenery, such theatrical effects as fires and storms can be suggested by the music. Many oratorios have a narrator who introduces the story and supplies details.

Oratorios developed from musical settings of religious texts during the Middle Ages. However, the form as it is known today emerged in Rome in the mid-1500's. The most important period of oratorio composition was the 1600's and 1700's. The German-born composer George Frideric Handel was the greatest composer of oratorios. His *Messiah* (1742) is the most famous oratorio ever written. Amateur and professional groups, especially in the United States and the United Kingdom, still perform oratorios regularly. Katherine K. Preston

See also **Cantata; Handel, George Frideric.**

Oratory is the art of eloquent speaking. An *orator* is a speaker who tries to persuade listeners by logical arguments and emotional appeals to their feelings. An *oration* is a speech that uses principles of *rhetoric* (the art of using words for persuasion). An oration, unlike a public speech, has a formal style and includes similes, metaphors, and other figures of speech.

Beginnings. A mass of lawsuits arose when a democracy was established in Syracuse in Sicily in 466 B.C. They were brought by former exiles whose property had been seized by the tyrants. Many claims were several years old, and documentary evidence was often lacking. The claimants needed help in presenting their cases. Corax, a Sicilian Greek, was the first to supply this help, and is considered the founder of oratory. He established a system of rules for public speaking in the 460's B.C., with the aid of his pupil Tisias.

Corax said that a speech usually should have five parts. He described these parts as (1) *proem* (introduction); (2) narrative; (3) arguments; (4) subsidiary remarks; and (5) summary.

Other early teachers of rhetoric include Protagoras, who developed the principles of debate; Gorgias, who emphasized style; Hippias, who was chiefly interested in the use of memory; and Lysias, who "showed how perfect elegance could be joined to plainness."

The study of speechmaking spread to Athens. During the 400's B.C., almost all male Athenian citizens attended the general assembly, where public policies were debated. They took part in the formulation of policies and the administration of justice. In the courts, they acted as jurors. The decision in each case rested with the jury, because there were no judges. Those who brought the charges and those who defended themselves pleaded their own cases. This practice led to a study of speechmaking.

Charles R. Belinky, Photo Researchers

A male and female orangutan have different physical features. The male, *right,* has broad cheek pads and a large throat pouch. He is twice as big as the female, *left,* who has no cheek pads.

Classical orators. The first great Greek orator was Pericles. His speeches were reported by Thucydides in his famous *History of the Peloponnesian War.* Pericles's Funeral Oration is his best-known speech. The greatest Greek orator was Demosthenes. He is best known for his *Philippics,* speeches in which he attacked Philip II of Macedonia as a threat to Greek independence.

The outstanding Greek writer on rhetoric was Aristotle. He defined rhetoric as "the faculty of discovering in every case the available means of persuasion." Aristotle emphasized three methods of proof: (1) *ethical* (the influence of the speaker's personality); (2) *pathetic* (the influence of the speaker's use of emotional appeal); and (3) *logical* (the influence of the use of formal principles of reasoning in proof).

Cicero holds first place among the important early Roman orators. Authorities believe that the *Rhetorica ad Herennium* was written by Cicero about 86 B.C. It states that an orator must divide the preparation of a speech into five steps. These steps are: (1) *invention* (analysis of speech situation and audience, investigation and study of subject matter, and selection of speech materials); (2) *disposition* (the arrangement of the speech materials under what we now call introduction, discussion, and conclusion); (3) *style* (the use and grouping of words to express ideas clearly, accurately, vividly, and appropriately); (4) *memory* (methods of memorizing material); and (5) *delivery* (the oral presentation).

Book I of Cicero's *De Oratore,* written about 55 B.C., develops the theme that a great orator must be a person of great learning and that the "proper concern of an orator ... is language of power and elegance accommodated to the feelings and understandings of mankind." Book II emphasizes the importance of invention and disposition, with particular attention to court oratory. Book III deals with style and delivery.

Institutio Oratorio (The Training of an Orator), written by Quintilian about A.D. 90, was a complete manual for the training of public speakers. Even today, it is one of the most comprehensive works on training speakers.

Later orators. With the coming of Christianity, the preacher replaced the political speaker. Famous early preachers include Paul, John Chrysostom, and Augustine. Outstanding speakers for religious reform were Savonarola in the late 1400's and Martin Luther and John Calvin during the Reformation in the 1500's.

Political oratory again became important in the 1700's. During the French Revolution, Comte de Mirabeau spoke for the common people fighting royal authority.

Britain has produced many distinguished speakers. They include Edmund Burke, Benjamin Disraeli, William Gladstone, and Winston Churchill.

American orators include Patrick Henry, John C. Calhoun, Daniel Webster, Stephen A. Douglas, and William Jennings Bryan. James M. Copeland

Orbit is the path of a natural or artificial object that moves under the influence of a central force. In astronomy, the term *orbit* refers specifically to the path of any object whose motion is controlled by the gravitational pull of another object. Astronomers call the more massive of the two objects the *primary,* and the less massive one the *secondary.* The moon, for example, is a secondary that revolves around its primary, the earth. The earth, in turn, is a secondary that travels around its primary, the sun. Spacecraft can become secondaries of the earth or another planet, or of the moon or the sun.

The orbit of a secondary object within the gravitational pull of a primary object is a closed curve called an *ellipse.* Perfectly circular orbits rarely occur. In an elliptical orbit, the primary is not in the center of the ellipse. As a result, the secondary travels closer to the primary at certain times than at others. The point in the orbit where a secondary of the earth is nearest the earth is called the *perigee.* The farthest point is the *apogee.* For a secondary of the sun, the nearest point in the orbit is the *perihelion* and the farthest point is the *aphelion.*

WORLD BOOK diagram

The shape of the orbit taken by a *secondary* object around a *primary* object may be an ellipse, parabola, or hyperbola, as shown here. It is determined by the speed of the secondary in relation to the speed required to escape from the primary.

A secondary object may gain enough speed to escape the gravitational pull of its primary. If it attains such *escape velocity,* its orbit becomes an open curve called a *parabola.* If a secondary moves faster than escape velocity, its orbit is a flatter open curve called a *hyperbola.* A spacecraft that leaves its orbit around the earth during a journey toward another planet travels a hyperbolic orbit.
Lee J. Rickard

Orchestra seating is designed by the conductor to produce a certain blend of sounds. In this diagram, the strings form a semicircle around the conductor. The woodwind instruments are arranged in the center, with the percussion and brass sections at the rear.

Orchestra is a group of musicians who play together on various instruments. Some African and Asian orchestras consist entirely of percussion instruments, such as drums, gongs, and xylophones. But in most Western nations, a musical group is considered an orchestra only if it includes violins and other stringed instruments. An orchestra differs from a band, which consists chiefly of wind and percussion instruments.

Some orchestras, called *string orchestras,* have only stringed instruments. On the other hand, *dance orchestras* resemble bands in most ways but may include a small string section. The word *orchestra* generally refers to a *symphony orchestra,* which consists mainly of stringed instruments. Symphony orchestras also have woodwind, brass, and percussion instruments, which enable them to produce a full range of musical sounds.

Symphony orchestras play all types of music, but most of them specialize in classical works. An orchestra may perform alone, or it may accompany one or more instrumental or vocal soloists or a chorus. Orchestras also accompany ballets and operas and provide background music for motion pictures and television productions.

Some symphony orchestras are made up entirely of professional musicians. Most of the world's major cities have a professional symphony, and some cities have several. They include such large, well-known orchestras as the Berlin Philharmonic, the Boston Symphony, the Chicago Symphony, the London Symphony, the New York Philharmonic, the Philadelphia Orchestra, and the Vienna Philharmonic. Many smaller communities, especially in Western countries, also have a symphony orchestra. These orchestras consist chiefly of amateur musicians. Many schools in Western countries have student orchestras.

The structure of a symphony orchestra

Orchestral music is written in the form of a *score,* which shows the notes to be played by each instrument. Most scores call for about the same kinds of instruments, and so most orchestras have a similar structure. A typical orchestra has about 20 kinds of instruments, but the number of each varies among different groups. A large orchestra may have more than 100 musicians, and small orchestras have from about 15 to 40 players. The small groups are often called *chamber orchestras.* During a performance, only the conductor follows the complete score. The printed music used by the musicians shows only their individual parts.

The musicians are divided into four main groups called *sections:* (1) the string section, (2) the woodwind section, (3) the brass section, and (4) the percussion section. The various instruments in the string, woodwind, and brass sections are pitched in different ranges, like the voices in a chorus. In the following discussion, the instruments in each of these sections are listed in order from those of the highest range to those of the lowest. Some percussion instruments are also tuned to definite pitches, but most of them have an indefinite pitch.

The string section is the heart of a symphony orchestra. It has more than half the musicians and consists of from 20 to 32 violins, 8 to 10 violas, 8 to 10 cellos, and 6 to 10 string basses. The violinists are divided into two groups of equal size. The *first violins* play the highest-pitched part in the string section, and the *second violins* play the next highest part. The leading first violinist

The Saint Paul Chamber Orchestra

Chicago Symphony Orchestra (Jim Steere)

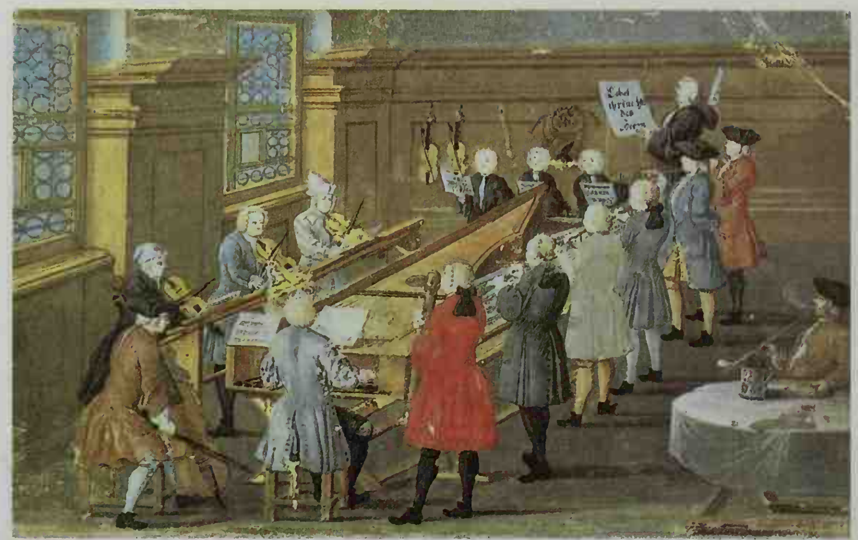
An orchestra, also called a *symphony orchestra, above,* consists chiefly of stringed instruments. A typical symphony orchestra also includes woodwind, brass, and percussion instruments. This type of orchestra may have more than 100 musicians. A small orchestra, *top,* often called a chamber orchestra, normally has about 15 to 40 musicians.

serves as *concertmaster* of the orchestra. The concertmaster directs the other musicians in tuning their instruments and may also be the orchestra's assistant conductor.

The woodwind section consists chiefly of flutes, oboes, clarinets, and bassoons. An orchestra has from 2 to 4 of each of these instruments. The musicians in the section also play various other woodwind instruments when a score requires them to do so. For example, a flutist may switch to the piccolo, and an oboe player may double on the English horn.

The brass section consists of 2 to 5 trumpets, 2 to 8 French horns, 2 to 4 trombones, and 1 tuba.

The percussion section includes two or more *timpani,* or kettle drums; bells and cymbals; wood blocks; and a bass drum, gong, snare drum, triangle, tambourine, and xylophone.



Other instruments are added to an orchestra if a score calls for them. They include such instruments as the harp, harpsichord, organ, piano, synthesizer, and various saxophones.

The conductor directs the musicians by keeping time with the baton or with his or her hands, and by means of gestures and facial expressions. However, conductors do their most important work before a performance—and even before rehearsing a composition. In most cases, the conductor selects the music to be played at a concert. After selecting a work, the conductor's first job is to *interpret* the music by deciding exactly how it should be played. Interpretation of a work includes such elements as tempo, tonal quality, and phrasing. After determining these features of the score, the conductor rehearses the music with the players.

During a rehearsal, the conductor asks individual musicians or sections to play various parts of the score again and again until the desired effect has been achieved. He or she strives for the correct balance among the many instruments playing at the same time and adjusts the sound to suit the acoustics of the performance hall. The finest conductors are respected not only for their musical skill but also for their ability to inspire both musicians and audiences.

Most conductors also help audition musicians who apply for positions in an orchestra. A conductor listens to the applicants perform and then recommends who should be invited to join.

Orchestra management. Most major orchestras in the United States are operated by private, nonprofit corporations called *symphony societies.* The chief concern of a symphony society is to raise funds to help support the orchestra. The board of directors of the society also acts on the conductor's recommendations regarding

Germanisches National Museum

Orchestras of the 1700's performed in the homes of wealthy patrons. This painting from about 1775 shows a typical orchestra of the time. The performers gather around an early keyboard instrument called a *harpsichord.*

musicians to be offered positions in the orchestra.

Most professional orchestras have a business manager to handle most of the administrative work. The business manager works out the orchestra's budget; prepares employment contracts; plans rehearsal, concert, and recording schedules; and organizes ticket sales and publicity.

History

The term *orchestra* was first used by the ancient Greeks for the front area of a stage. During the Middle Ages, *orchestra* came to mean the musicians on that part of the stage. In modern times, *orchestra* has come to mean both the musicians on stage and the seats directly in front of the stage.

Beginnings. The first orchestras were organized at the royal court of France and in Italian churches and palaces during the late 1500's and the 1600's. At first, orchestras served chiefly to accompany social dances, ballets, religious vocal music, and operas. Most of these orchestras consisted mainly of string instruments. In Germany, wind instruments were also popular. Except in France, these orchestras had no standard structure. String, wind, and percussion instruments were often mixed. The orchestra of King Louis XIII of France was the first standardized orchestra. It had 24 instruments of the violin family, divided into five sections, and 12 wind instruments. Beginning in the 1600's, most orchestras also played a bass line called a *basso continuo,* usually with a lute, harp, organ, or harpsichord.

The 1700's and 1800's. By the early 1700's, some European composers also began to write music for orchestra in its own right. These composers included Johann Sebastian Bach, Arcangelo Corelli, George Frideric Handel, and Antonio Vivaldi. Their compositions were called *concerti, concerti grossi, overtures,* and *suites.*

Orchestral works called *symphonies* first appeared as overtures or small instrumental interludes in operas about 1600. By the 1720's and 1730's Giovanni Battista Sammartini began to write independent string symphonies in Italy. In the late 1700's, Joseph Haydn and Wolfgang Mozart, perfected the *classical symphony.* The clarinet became standard in the symphony orchestra in the 1790's. In the early 1800's, Ludwig van Beethoven composed the first symphonies that included trombones and voices.

During the 1800's, cities began to take over patronage of orchestras. Many orchestras were regularly engaged in accompanying operas in municipal opera houses and also played concerts on the side. A few, however, were established independently of the opera. The Gewandhaus Orchestra of Leipzig, Germany, is the oldest orchestra still playing. It was founded in 1781. The Paris Conservatory Orchestra was established in 1800, and what is now the Royal Philharmonic Society was founded in 1813.

Until the early 1800's, orchestras were small enough to perform without a conductor. The concertmaster or a keyboard player in the basso continuo served as the leader. By 1830, orchestras had grown so large that nearly all were led by a conductor. Composers Hector Berlioz and Felix Mendelssohn were among the earliest conductors. Berlioz was one of the first to conduct with a baton.

Popular types of orchestral music in the 1800's included symphonies, overtures, symphonic poems, and concertos. Orchestras also continued to accompany opera, ballet, and religious music. In the late 1800's and early 1900's, such composers as Richard Wagner, Anton Bruckner, Gustav Mahler, and Richard Strauss wrote works for orchestras of 100 or more musicians.

Modern orchestras. Since the early 1900's, there has been renewed interest in works for smaller orchestras. Some composers have added electronic instruments or reorganized the orchestra into groups to create new kinds of musical sounds. Today, most large orchestras have several conductors on their staffs.

The symphony orchestra originated in Europe, but its form has been copied throughout the world. There are now many symphony orchestras in non-European countries including Argentina, Australia, Brazil, China, Israel, Japan, and Mexico. The first orchestras in the United

States were formed in the late 1700's. The oldest American orchestra still performing is the student orchestra at Harvard University, which was formed in 1808. Important orchestras in the United States include the New York Philharmonic (1842), the Boston Symphony (1881), the Chicago Symphony (1891), and the Philadelphia Orchestra (1900).

The cost of maintaining an orchestra has increased dramatically since the mid-1900's. The income from ticket sales pays only a fraction of an orchestra's expenses. Many European orchestras rely heavily on funds that they receive from government sources. In the United States, many orchestras receive additional funds from both private and public sources and from recording royalties. Organizations such as the National Endowment for the Arts, an independent federal agency, distribute funds to symphony societies. Some orchestras have sought other sources of funding in new types of programming. For example, these orchestras have provided background music for movies, radio, and videos.

Orchestra bells imitate the effect of authentic cast bronze bells. The two types of orchestra bells are tubular chimes and metal bars. The chimes are usually from 1 to 2 inches (2.5 to 5.1 centimeters) in diameter and vary in length with the pitch. They are hung from a metal frame, and are struck with heavy leather-headed mallets. Their sound is deep and resonant. The metal bars are of varying sizes, usually not more than $\frac{1}{2}$ inch (13 millimeters) in thickness, and are arranged in rows much like the piano keyboard. They are struck with a hard mallet, and produce a ringing sound, more brilliant and higher pitched than that of the tubular, hanging chimes.

Orchid, *AWR kihd,* is any of an extremely large family of plants, many of which bear beautiful flowers. There are as many as 20,000 species of these plants. They are widely cultivated as house, garden, and greenhouse flowers, and they also grow wild. Orchids are *perennials,* which means the plants live for at least three years.

Orchids range in size from small plants only $\frac{1}{4}$ inch (0.6 centimeter) high to vines as much as 100 feet (30 meters) long. The flowers come in all colors except black, and they may be speckled or streaked.

Wild orchids grow in all parts of the world except Antarctica. They are most abundant in regions with plentiful rainfall. Most species grow on the trunks and branches of trees, or on rocks, in warm or tropical areas. Wild orchids that live in cooler regions grow on the ground. Some species even inhabit desert regions. The Australian *underground orchids* live below the surface of the soil in order to conserve water.

Parts of orchids. Like lilies, orchids have three inner petals and three outer, petallike *sepals.* However, unlike lilies, orchids have a central petal that is usually larger and more showy than the other petals. This petal is called the *lip* or *labellum.* It may look like a cup, a scoop, a trumpet, or a bag. Among most orchids, each flower has one *stamen* (male part) and one *pistil* (female part) at its center. The stamen bears pollen grains, which usually occur in large clusters called *pollinia.* The pollen produces sperm cells, while the pistil contains egg cells. Among these orchids, the stamen and the pistil are joined, forming a *column.*

How orchids reproduce. Most orchids reproduce by *cross-pollination.* In this process, an insect, a bat, or a bird carries pollen from the stamen of one flower to the pistil of a flower of another plant. An orchid's fragrance and the size and shape of its blossoms may attract certain kinds of insects or birds. For example, many orchids look or smell like bees, attracting bees to the flowers.

After pollination occurs, sperm cells unite with egg cells in the pistil and seeds develop. Orchid seeds are so tiny that they need the help of certain types of fungi

Some kinds of orchids

As many as 20,000 species of orchids grow in most parts of the world. These beautiful flowers have a wide variety of shapes and colors. Some of the orchids shown below grow in various countries and have no common name in English. The scientific name is given for such flowers.

to begin their growth. These fungi supply the seeds with various substances needed for growth.

Kinds of orchids. Most botanists divide orchids into three groups, according to the number of stamens and the form of the column in the flower. The largest group of orchids—more than 96 percent of all species—have flowers with a completely joined column that typically contains one stamen. This group includes the vinelike *vanilla orchids,* which grow in Mexico and throughout the tropics. Vanilla, a flavoring in many foods and beverages, occurs naturally in these orchids (see **Vanilla**).

Species with two stamens almost completely joined in the column make up a group called *lady's-slipper orchids* (see **Lady's-slipper**). A third group consists of orchids with two or three stamens that are at most only partly joined in the column. Margaret R. Bolick

Scientific classification. Orchids make up the orchid family, Orchidaceae. There are three subfamilies: Orchidoideae, Cypripedioideae, and Apostasioideae.

Orcus. See **Pluto**.

Orczy, *AWRT see,* **Baroness** (1865-1947), was a Hungarian-born English author known chiefly for her adventure-filled novels and detective stories. She also wrote several plays.

Culver
Baroness Orczy

Orczy's most famous novel, *The Scarlet Pimpernel* (1905), is set during the French Revolution (1789-1799). The hero, an English aristocrat named Sir Percy Blakeney, appears to be an idle, useless person. But, as the mysterious Scarlet Pimpernel, he gallantly rescues aristocrats who have been sentenced to death. This character also appears in 12 other novels.

Orczy created several detectives in various short stories. For example, the nameless Old Man in the Corner solves baffling crimes as he sits in a corner of a London teashop, knotting and unknotting a piece of string. He appears in the story collection *The Old Man in the Corner* (1909). Another detective, Lady Molly Robertson-Kirk, one of the first female detectives, is featured in the collection *Lady Molly of Scotland Yard* (1910).

Baroness Emmuska Orczy was born in Tarnaörs, Hungary, near Jászberény. Her family moved to London when she was 15. David Geherin

Order is a unit of scientific classification. Organisms are divided into seven major groups called kingdoms, phyla, or divisions; classes; orders; families; genera; and species. Members of an order are more closely related than are members of a class. However, members of orders are not so closely related as are members of families. Theodore J. Crovello

See also **Classification, Scientific** (table).

Order in Council is a decree issued by the British Crown when a matter of great importance confronts the nation. Orders in Council get their name from the fact that they are proclaimed with the advice of the Privy Council. In 1807, Britain issued Orders in Council in answer to Napoleon's threat to blockade the island empire. By these orders, British ships blockaded the European coast and kept neutral trading vessels from entering ports of Napoleonic Europe. See also **Continental System; Privy Council.** Arthur Cyr

Order of ... See articles on orders listed under their key word, as in **DeMolay, Order of.**

Ordered pair. See **Algebra** (Functions).

Ordinance is a public law or regulation that is usually made by the governing body of a city, town, or village. In most cases, ordinances are only local in nature.

The name *ordinance* has also been given to regulations that serve as laws in newly settled territories, but are not actually constitutions. The Ordinance of 1787 was such a regulation. It provided for government in the Northwest Territory (see **Northwest Ordinance**). *Ordinance* may also refer to a church sacrament, such as Communion. Susan H. Ambler

Ordinance of 1785. See **Westward movement in America** (Reaching the Mississippi River).

Ordinance of 1787. See **Northwest Ordinance.**

Ordnance, *AWRD nuhns,* is a military term used for weapons and ammunition. Most armies, navies, and air forces have ordnance departments. It is the responsibility of the ordnance departments to design, make, repair, and distribute weapons and ammunition. The term *ordnance* also includes the tools used in the manufacture and maintenance of these items. Frances M. Lussier

See also **Ammunition; Weapon.**

Ordovician Period. See **Earth** (table: Outline of Earth's history).

Ore is a mineral or rock that contains enough metal to make it worth mining. Ore deposits often occur in cracks of rocks called *veins* and in layers known as *beds.* Ore spread thinly in rock is *disseminated ore.* Worthless minerals mixed in with ore are called *gangue.*

There are two types of ores—*native metals* and *compound ores.* In *native metals,* the valuable mineral occurs as a pure metal. It is not chemically combined with other substances. Gold, silver, platinum, and copper often occur as native metals. In *compound ores,* the valuable metal is joined to other substances such as oxygen, sulfur, carbon, or silicon to form various chemical compounds. The ores of iron, aluminum, and tin are usually found joined with oxygen in compounds called *oxides.* Copper, lead, zinc, silver, nickel, and mercury are found joined with sulfur in compounds called *sulfides.*

Metal is separated from ore in various ways. In a process called *concentration,* ore is crushed and ground so that metals separate from gangue. Metals can also be freed from ore and refined by *smelting,* in which ore is melted. Some metals can be dissolved out of ore by a process called *leaching.* In the *electrolysis* process, metals are separated by passing an electric current through a solution that contains metal atoms. See **Metallurgy** (Extractive metallurgy). William Hustrulid

See also **Mineral; Rock.**

Oregano, *uh REHG uh noh* or *awr uh GAH noh,* is a seasoning used in many popular foods, including pizza and spaghetti sauce. Oregano commonly is prepared from the dried leaves of the wild marjoram plant. Oregano has a strong, sweet flavor. See also **Marjoram.**

Ed Cooper, StockFile

Cannon Beach lies along the rocky Pacific coast in the northern part of Oregon. Oregon's rugged shoreline, scenic mountains, and vast evergreen forests attract millions of tourists every year.

Oregon *The Beaver State*

Oregon, a Pacific Coast state of the United States, is known for its vast forests of evergreen trees. Forests cover almost half the state, and many large Oregon cities have factories that make wood products. The state has about a tenth of the nation's timber, and it ranks among the leading states in lumber production.

The rugged beauty of Oregon's mountains, seacoast, and forest lands attracts millions of tourists every year. Hunters shoot deer and elk and other game in Oregon's wooded regions. People enjoy fishing in the sparkling lakes and rivers, and in Pacific waters.

Oregon is often called the *Pacific Wonderland* because of its outstanding natural wonders. These include Crater Lake in the Cascade Mountains, the Columbia River Gorge, Hells Canyon on the Snake River, and Oregon Caves National Monument. Mount Hood, Mount Jefferson, and other snow-covered peaks rise majestically in the Cascade Range. The Wallowas, in northeastern Oregon, also offer spectacular mountain scenery. Steep cliffs rise along much of Oregon's wave-swept coast. But parts of the coast have sandy beaches and protected harbors.

The dry lands east of the Cascade Mountains have large livestock ranches. Potatoes, sugar beets, and other vegetables grow in irrigated areas of eastern Oregon. Wheat, Oregon's most valuable food crop, comes chiefly from the north-central area of the state. Orchard fruits grown in the Hood and Rogue river valleys are world famous.

The mighty Columbia River forms most of the boundary between Oregon and Washington. Huge dams on the Columbia supply electric power for homes and industries. The dams also improve the river for shipping, and provide water for irrigation.

The contributors of this article are Claude W. Curran, Professor of Geography at Southern Oregon University; and Gordon B. Dodds, Professor of History at Portland State University.

Ed Cooper, StockFile

Vast fields of golden wheat grow in the plateau area of north-central Oregon. Wheat is one of the state's most valuable crops.

The Columbia River was at one time called the Oregon, or *Ouragan,* which means *hurricane* in French. Some authorities think that Oregon's name came from this historic name. Oregon is known as the *Beaver State* because the region supplied thousands of beaver skins during fur-trading days.

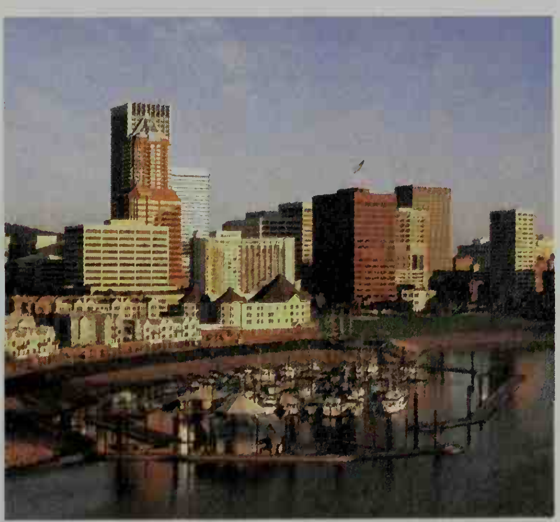
In the early days, Oregon meant the end of the trail for many pioneers. During the 1840's and 1850's, thousands of settlers traveled by covered wagon on the Oregon Trail to the fertile farmlands of the Willamette Valley.

Today, the Willamette Valley is Oregon's greatest center for trade and industry. It is also important for flower bulbs, fruits, milk, seed crops, and vegetables. Most of Oregon's large cities are in the Willamette Valley. They include Portland, the largest city, and Salem, the state capital. Portland extends along both banks of the Willamette River near the place where the Willamette flows into the Columbia. It is an industrial city and a major seaport.

Interesting facts about Oregon

WORLD BOOK illustrations by Kevin Chadwick

Lava forest



The world's largest forest of lava-cast trees is located on the slopes of Newberry Volcano in Deschutes National Forest, south of Bend. The imprint of pine bark is still visible on the insides of many casts, which were formed about 6,000 years ago when molten lava flowed into a living pine forest. The lava cooled against the tree trunks, which caught fire and burned away, leaving perfect molds. The forest covers about 4 square miles (10 square kilometers).

The first state antilitter law affecting nearly all beverage containers was passed by the Oregon legislature on July 2, 1971, and became effective on Oct. 1, 1972. The law outlaws pull-tab cans and requires that all beverage cans and most types of bottles be returnable for a cash refund.

The world's smallest official park is located on a traffic island on S. W. Front Avenue in Portland. Mill Ends Park is 24 inches (61 centimeters) across and has a total area of 452 square inches (2,916 square centimeters). A Portland journalist, Dick Fagan, created the park on St. Patrick's Day, 1948, as a colony for leprechauns and a site for snail races. It became a city park in 1976.

World's smallest park

David Falconer, Frazier Photolibrary

Downtown Portland rises along the west bank of the Willamette River near Oregon's northern border. Portland is Oregon's largest city and the state's major center of industry and trade.

Oregon in brief

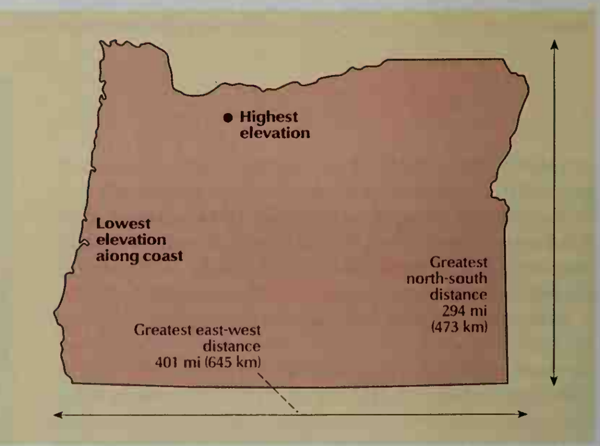
Symbols of Oregon

The state flag, adopted in 1925, bears the state seal. The seal, adopted in 1859, has 33 stars around it to show that Oregon was the 33rd state. The seal includes an ox-drawn wagon to symbolize the settling of the region by pioneers. The reverse side of Oregon's flag, *not shown,* has an illustration of a beaver, the state animal. Oregon is the only state whose flag has a different design on the reverse side.

State flag

State seal

Oregon (brown) ranks 10th in size among all the states and 2nd in size among the Pacific Coast States (yellow).



The State Capitol is in Salem, the capital since statehood in 1859. Earlier capitals were Oregon City (1849-1851), Salem (1851-1859), and Corvallis (1855, for six months).

General information

Statehood: Feb. 14, 1859, the 33rd state.
State abbreviations: Ore. or Oreg. (traditional); OR (postal).
State motto: *She Flies with Her Own Wings.*
State song: "Oregon, My Oregon." Words by J. A. Buchanan; music by Henry B. Murtagh.

Land and climate

Area: 97,052 mi² (251,365 km²), including 1,050 mi² (2,718 km²) of inland water but excluding 80 mi² (207 km²) of coastal water.
Elevation: *Highest*—Mount Hood, 11,239 ft (3,426 m) above sea level. *Lowest*—sea level.
Coastline: 296 mi (476 km).
Record high temperature: 119 °F (48 °C) at Prineville on July 29, 1898, and at Pendleton on Aug. 10, 1898.
Record low temperature: −54 °F (−48 °C) at Ukiah on Feb. 9, 1933, and at Seneca on Feb. 10, 1933.
Average July temperature: 66 °F (19 °C).
Average January temperature: 32 °F (0 °C).
Average yearly precipitation: 28 in (71 cm).

Important dates

1792 Robert Gray sailed into the Columbia River.

1811 John Jacob Astor's Pacific Fur Company founded Astoria.

1819 A treaty between the United States and Spain fixed the present southern border of Oregon.

1848 Oregon became a territory.

Sources of information

For information about tourism, write to: Oregon Tourism Commission, 775 Summer Street NE, Salem, OR 97301-1282. The Web site at www.traveloregon.com also provides information.

For information on the economy, write to: Oregon Economic & Community Development Department, 775 Summer Street NE, Salem, OR 97301-1280.

The state's official Web site at www.state.or.us also provides a gateway to much information on Oregon's economy, government, and history.

1859 Oregon became the 33rd state on February 14.

1902 Oregon adopted the initiative and referendum, procedures that permit voters to take a direct part in lawmaking.

1937 Bonneville Dam was completed.

1982 Construction was completed on a second powerhouse of Bonneville Dam.

People

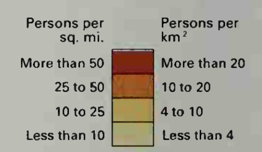
Population. The 2000 United States census reported that Oregon had 3,421,399 people. The state's population had increased 20 percent over the 1990 census figure, 2,842,321. According to the 2000 U.S. census, Oregon ranks 28th in population among the 50 states.

About three-fourths of the people of Oregon live in the state's metropolitan areas (see **Metropolitan area**). For the names and populations of these areas, see the *Index* to the political map of Oregon.

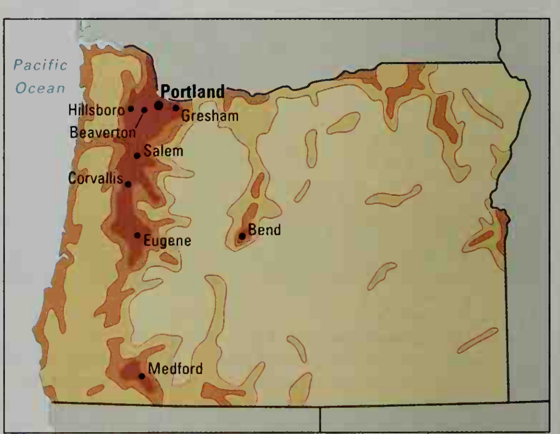
Most of Oregon's large cities lie in the rich Willamette Valley in the northwestern part of the state. Portland, Oregon's largest city, is the commercial, industrial, and cultural center of the state. Portland's lovely rose gardens give it the nickname *City of Roses*.

Eugene ranks as the second largest city in Oregon. Eugene is a trading and processing center. The largest cities outside the valley are Ashland and Medford in the southwest, and Bend in central Oregon.

Some of Oregon's people trace their ancestry to settlers who came on the Oregon Trail. Oregon's largest population groups include people of German, English, Irish, American Indian, French, Swedish, and Norwegian descent.



Schools. Jason Lee, a Methodist missionary, established a school for Indian children in French Prairie as early as 1834. After the Oregon Territory was organized



David Falconer, Frazier Photolibrary

A rose garden in Portland attracts flower lovers. Portland is nicknamed *City of Roses* because of its many public and private rose gardens. Roses thrive in the city's mild, moist climate.

Population density

More than half of Oregon's residents live in the Willamette Valley, in the northwestern part of the state. Thinly populated eastern Oregon is largely mountainous.

WORLD BOOK map; based on U.S. Census Bureau data

Chris Luneski

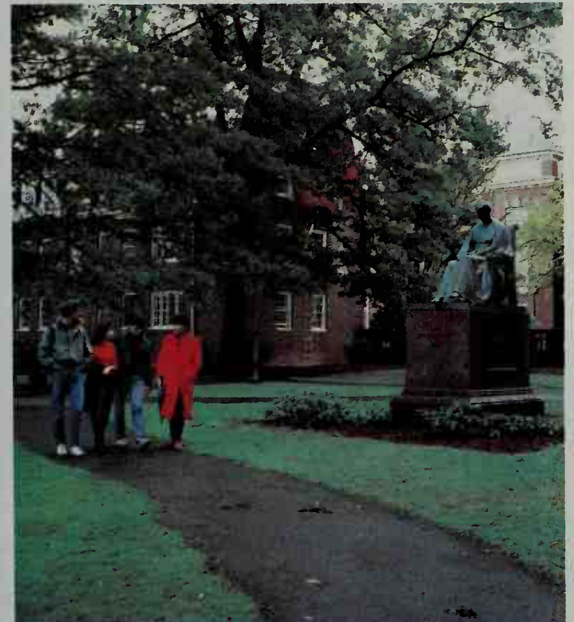
Runners in Eugene compete in the annual Butte to Butte 10-Kilometer Run through the city. Eugene, Oregon's second largest city, is a favorite training site for world-class athletes because of its extensive running facilities.

in 1848, an act provided that income from two sections (1,280 acres, or 518 hectares) of land in each township should be set aside for education. In 1849, the territorial legislature passed laws providing for a free public school system. The first public school in Oregon opened in 1851.

Today, a State Board of Education heads Oregon's public school system. The governor appoints the seven board members, subject to approval by the state Senate. The superintendent of public instruction is elected to a four-year term. The superintendent oversees the public school system.

Children from age 7 through 17 must attend school. For the number of students and teachers in Oregon, see **Education** (table).

Libraries. Oregon's first subscription library was organized in Oregon City in 1834. The Library Association of Portland (now the Multnomah County Library) was the first to serve the public on a large scale. It began in 1864 on a membership basis and became a free public library in 1902.



Today, Oregon has about 200 public libraries and branches. The largest library in the state is the Multnomah County Library in Portland. The Oregon State Library in Salem provides information to the state government and serves as the library for the blind.

Museums. The Portland Art Museum displays a large collection of paintings and sculpture. These works feature Indian art from the Northwest Coast and pre-Columbian Mexican art. The University of Oregon Museum of Art in Eugene owns the Murray Warner Collection of Oriental Art, one of the finest in the country. The Oregon Museum of Science and Industry in Portland features interactive exhibits representing every major branch of science. The Oregon Historical Society in Portland features exhibits from pioneer days. The Favell Museum of Western Art and Indian Artifacts is in Klamath Falls.

Universities and colleges

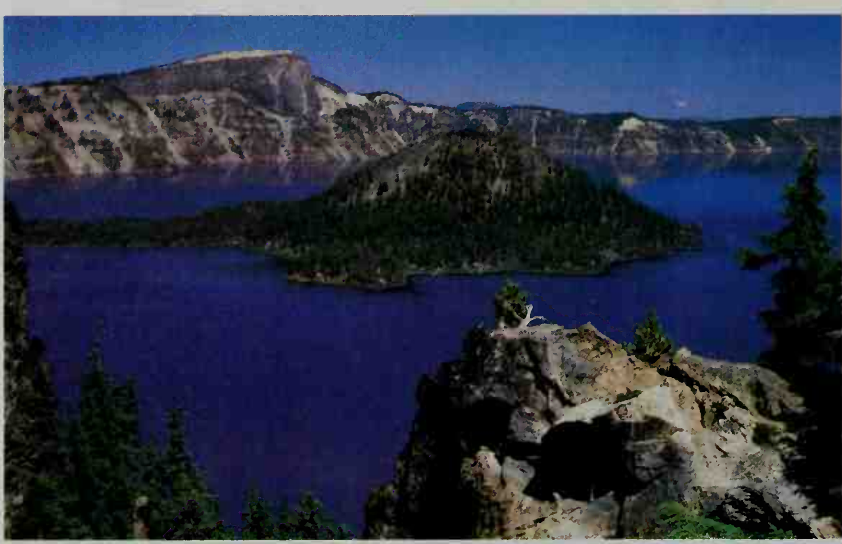
*Does not appear on map; key shows general location.
†Census designated place—unincorporated, but recognized as a significant settled community by the U.S. Census Bureau.

°County seat.
Places without population figures are unincorporated areas.
Source: 2000 census.

Steve Terrill

Mount Hood, Oregon's highest peak, rises 11,239 feet (3,426 meters) above sea level. The mountain, an inactive volcano, is located about 50 miles (80 kilometers) east of Portland.

Visitor's guide



Oregon is known for its beautiful mountains and coastal scenery. Majestic snow-covered Mount Hood towers above the Cascade Range about 50 miles (80 kilometers) east of Portland. U.S. Highway 26 skirts Mount Hood and offers close-up views of its glacier-clad slopes. U.S. Highway 101 follows the Oregon coastline for about 300 miles (480 kilometers). Motorists driving along this route see views of white sand dunes, coastal lakes and bays, and cliffs rising above the shore.

Oregon is a recreational paradise. Deer, elk, and pronghorns roam the fields and forests. People catch salmon, steelhead, trout, and other major game fish. Grouse, pheasant, quail, and other game birds are plentiful.

Slopes in the Cascade, Siskiyou, and Blue mountains offer excellent skiing. Timberline, on Mount Hood, offers year-round skiing. The skiing season in most other areas begins in November and lasts through April.

One of Oregon's most famous events is the Oregon Shakespeare Festival in Ashland. Indoor plays are presented from late February through late October. Outdoor plays are presented from June through September. "Dancing on the Green" before showtime features Shakespearean songs.

Other leading events are the Portland Rose Festival in early June and the Pendleton Round-Up and Happy Canyon Pageant in mid-September. The Rose Festival features parades, stage events, an international rose show, auto races, and a carnival. The festival's main event is a spectacular Grand Floral Parade. The four-day rodeo includes a presentation by local Indian tribes featuring a tepee camp and ceremonial dancing.

Ed Cooper, StockFile

Crater Lake, deepest lake in the United States

Places to visit

Following are brief descriptions of some of Oregon's many interesting places to visit:

Bonneville Dam, the first major dam on the Columbia River, has a series of fish ladders. In season, salmon and other fish jump up the ladders on their way upstream to spawn.

Columbia River Gorge. Here the Columbia River cuts through the Cascade Mountains. Colorful basalt cliffs line the gorge for about 60 miles (97 kilometers) between The Dalles and Troutdale. A number of waterfalls tumble into the gorge.

The Museum at Warm Springs has interactive historical exhibits and collections of art and artifacts from the Confederated Tribes of the Warm Springs Reservation of Oregon.

National Historic Oregon Trail Interpretive Center, in Baker City, has exhibits and demonstrations that re-create some of the experience of traveling along the Oregon Trail.

Sea Lion Caves, on the Pacific Coast near Florence, house hundreds of sea lions. The animals can be seen in the caves and on nearby rocks. It is the world's largest sea cave.

National parks and forests. Crater Lake National Park, the state's only national park, lies in the Cascade Mountains in south-central Oregon. Crater Lake, 1,932 feet (589 meters) deep, rests at the top of an ancient volcano. See **Crater Lake National Park.** Ten national forests lie entirely within Oregon. They are Deschutes, Fremont, Malheur, Mount Hood, Ochoco, Siuslaw, Umpqua, Wallowa-Whitman, Willamette, and Winema. Oregon shares Umatilla National Forest with Washington, and Klamath, Rogue River, and Siskiyou national forests with California. Congress set aside 13 areas in Oregon's national forests as national wilderness areas, to be preserved in their natural condition.

National monuments, memorials, and historic sites. Oregon Caves National Monument is in southwestern Oregon's Siskiyou Mountains. Its limestone caverns contain beautiful stone formations. John Day Fossil Beds National Monument in north-central Oregon features fossils of prehistoric animals and plants (see **John Day Fossil Beds National Monument**). Fort Clatsop National Memorial near Astoria was the site of the winter camp of Meriwether Lewis and William Clark during their expedition to the area in 1805 and 1806. McLoughlin House National Historic Site in Oregon City was built by John McLoughlin, who is often called the *Father of Oregon.* He lived there from 1847 to 1857.

State parks. Oregon has over 230 state parks. Many have camping and recreational facilities. Write to Oregon State Parks, 1115 Commercial Street NE, Salem, OR 97301-1002.

Annual events

January-May
Sled Dog Races in Chemult (January); Seafood and Wine Festival in Newport (late February); Pear Blossom Festival in Medford (mid-April); All Northwest Barber Shop Ballad Contest and Gay Nineties Festival in Forest Grove (early May); Rhododendron Festival in Florence (mid-May); Fleet of Flowers Memorial Service in Depoe Bay (late May).

June-August
Cannon Beach Sandcastle Contest in Cannon Beach (June); Rose Festival in Portland (June); Strawberry Festival in Lebanon (early June); Bach Summer Music Festival at Eugene (late June); World Class Windsurfing in Hood River (July); Butte to Butte 10K run in Eugene (early July); Rodeo in St. Paul (early July); World Championship Timber Carnival in Albany (early July); Buckeroo in Molalla (early July); Chief Joseph Days in Joseph (late July); Oregon Brewers Festival in Portland (late July); Regatta in Astoria (mid-August); State Fair in Salem (August-September).

September-December
Oktoberfest in Mount Angel (mid-September); Cycle Oregon Bike Ride, different location each year (September); Lord's Acre Auction and Barbecue in Powell Butte (early November); Kraut and Sausage Feed and Bazaar in Verboort (November). Whale Watching on the Oregon coast (November-December).

Shakespeare Festival in Ashland

Land and climate

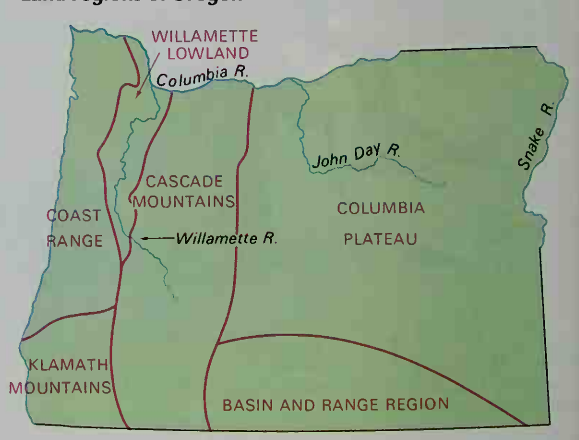
Land regions. Oregon has six main land regions. They are: (1) the Coast Range, (2) the Willamette Lowland, (3) the Cascade Mountains, (4) the Klamath Mountains, (5) the Columbia Plateau, and (6) the Basin and Range Region.

The Coast Range region borders the Pacific Ocean from Washington's Chehalis Valley on the north to the Klamath Mountains of Oregon on the south. The rolling coast ranges run parallel to the shoreline. They are the lowest of Oregon's main mountain ranges, with average elevations of less than 2,000 feet (610 meters). Marys Peak, southwest of Corvallis, rises 4,097 feet (1,249 meters) and is the highest point in the region. Forests of Douglas-fir, hemlock, spruce, and other evergreen trees cover much of the area.

Several valleys in the region, such as Triangle Lake Valley, are beds of ancient lakes. Many small coastal lakes were formed when the mouths of streams sank and sand dunes dammed their waters. Along much of the coast, the land rises from the sea in sheer cliffs, some of them nearly 1,000 feet (300 meters) high. In some places, the coastal mountains rise in a series of terraces. Each terrace was once the coastline.

The Willamette Lowland is a narrow strip wedged between the Coast Range on the west and the Cascade Mountains on the east. The Willamette River and its branches flow north to the Columbia River. They drain the farm and forest lands of the Willamette Valley. Over half the state's people live in the region. Rich soil and a favorable climate make it the most important farming and industrial area in the state.

The Cascade Mountains region, a broad belt of rugged land crowned by volcanic peaks, includes some of the highest mountains in North America. Mount Hood, the highest peak in Oregon, rises 11,239 feet (3,426 meters) above sea level. Mount Jefferson is 10,497 feet (3,199 meters) high. Other beautiful peaks in the Cascade Mountains include the Three Sisters, more than 10,000 feet (3,000 meters) high, and Mount McLoughlin, 9,495 feet (2,894 meters) high.



The Klamath Mountains cover the southwestern corner of Oregon. Thick forests grow on the mountainsides and provide shelter for a variety of animals. This region also has the state's richest mineral deposits.

The Columbia Plateau, also called *the Columbia Intermontane,* covers most of eastern Oregon and extends into Washington and Idaho. Thousands of years ago, lava flowed out of cracks in the earth's crust to form the plateau. Deep canyons of the Deschutes, John Day, and other rivers cut through the plateau in north-central Oregon. The state's great wheat ranches lie there. Much of the so-called "plateau" in Oregon is actually rugged and mountainous. The Blue and Wallowa mountains rise in northeastern Oregon. Timberlands cover the Blue Mountain area. The Wallowa Mountains, cut by glaciers, provide spectacular scenery. The Snake River has carved the famous Hells Canyon on the Oregon-Idaho border. This great gorge lies between the Wallowa Mountains and Idaho's Seven Devils Mountains. Its average depth is about 5,500 feet (1,680 meters).

The Basin and Range Region covers part of southeastern Oregon and extends into California and other nearby states. In Oregon, the region consists of high basins broken by occasional steeply sloped mountains. The Cascade Range to the west cuts off moisture-bearing winds from the Pacific Ocean and makes much of the area a semidesert.

Coastline. Oregon's coastline extends 296 miles (476 kilometers) along the Pacific Ocean. Much of the shore

Specially created for *The World Book Encyclopedia* by Rand McNally and World Book editors

Grant Heilman

The towering Cascade Mountains include several peaks over 10,000 feet (3,000 meters) high. The Three Sisters rise in the foreground. Mount Jefferson and Mount Hood are in the distance.

is rugged, with steep cliffs rising up from the sea. But many bays and harbors have been formed where rivers from the coast ranges and Klamath Mountains flow into the sea. These bays and harbors include Tillamook, Yaquina, Alsea, Winchester, and Coos.

Rivers, waterfalls, and lakes. The mighty Columbia River flows westward to the Pacific Ocean, forming most of the border between Oregon and Washington. The Columbia drains more than half of Oregon. The Columbia and its branch, the Willamette River, form the largest system of navigable waterways in the state. The Snake River forms much of the Oregon-Idaho border. It joins the Columbia in Washington. The Snake and its branches drain the easternmost part of Oregon. The Deschutes River travels northward through central Oregon and empties into the Columbia. The John Day River rises in the Strawberry Mountains in eastern Oregon. It flows west and north to the Columbia and drains much of north-central Oregon.

Hundreds of streams in the Cascade Mountains rush down the slopes in rapids and waterfalls. Among the best known waterfalls are Benham, Pringle, Salt Creek, Steamboat, and the many falls along Silver Creek. About a dozen waterfalls, some of them over 200 feet (61 meters) high, tumble into the Columbia River Gorge. These waterfalls include Bridal Veil, Coopery, Elowah, Horsetail, Latourell, and Multnomah.

The Cascade Mountains region has many lakes. Crater Lake in the Cascades, 1,932 feet (589 meters) in depth, is the deepest lake in the United States. It lies in the *caldera* (crater) of an extinct volcano. Wallowa Lake in the Wallowa Mountains is famous for its sparkling clear water. Most of the lakes in southeastern Oregon are shallow and salty. Some evaporate during dry seasons and leave salt deposits in the lake beds. But a few, such as Harney and Malheur, are large year-round lakes. A number of small lakes near the Oregon coast were formed when deposits of soil and sand blocked the mouths of streams and kept the streams from emptying into the ocean.

Plant and animal life. Forests cover nearly half of Oregon. Softwood trees include cedars, firs, hemlocks, pines, and spruces. Hardwoods include alders, ashes, cottonwoods, junipers, madrones, maples, and willows. Many kinds of wild flowers grow in Oregon because the state has a variety of climates and elevations. Oregon is famous for its azaleas, laurels, and other flowering shrubs. The state flower, the Oregon grape, grows in most parts of the state.

Columbian black-tailed deer and Roosevelt elk live in Oregon's Cascade Mountains and coastal forests. Mule deer, Rocky Mountain elk, and Bighorn sheep are found east of the Cascades. Pronghorn antelope thrive in the southeast. A small number of mountain goats live in the Wallowa Mountains. Smaller animals found in Oregon include bobcats, beavers, coyotes, foxes, minks, muskrats, and river otters. Seals and sea lions live along the coast.

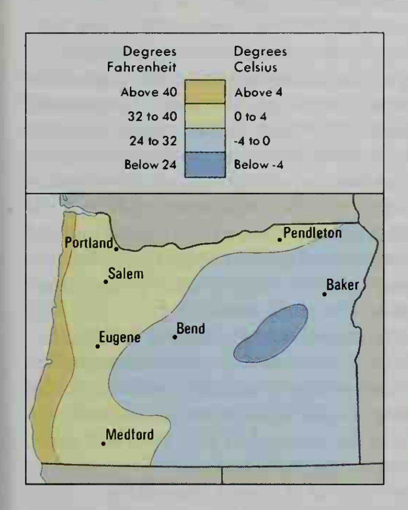
Every year, thousands of salmon leave the ocean and swim up Oregon's rivers to lay their eggs. They leap up low waterfalls and climb fish ladders to get around dams. Cod, halibut, herring, ling cod, sablefish, sole, and tuna live in Oregon's coastal waters.

The steelhead trout is perhaps the most prized of Oregon's many game fishes. Other fishes in the state's rivers and lakes include perch; striped bass; sturgeon; and cutthroat, brook, and rainbow trout.

Climate. Mild, moist winds from the Pacific Ocean give western Oregon an unusually mild climate for a state so far north. Coastal temperatures average 45° F. (7° C) in January and 60° F. (16° C) in July. The winds become cooler when they rise over the coast ranges. Much of their moisture condenses and falls as rain. In some coastal mountain areas, yearly *precipitation* (rain,

snow, and other moisture) exceeds 130 inches (330 centimeters).

In the Willamette Valley, east of the Coast Range, precipitation averages about 40 inches (100 centimeters) a year, almost all during the cool season. As the winds rise up the western slopes of the Cascade Mountains, more of their moisture falls. Precipitation in this area averages 50 to 75 inches (130 to 191 centimeters) a year.



The winds are usually dry by the time they have crossed the Cascades. Dry winds do not keep the climate mild, as moist winds do. For this reason, eastern Oregon has relatively cold winters and hot summers. In the southeast, temperatures average 27 °F (−3 °C) in January and 72 °F (22 °C) in July. Much of eastern Oregon receives only 6 to 12 inches (15 to 30 centimeters) of precipitation a year. Oregon's record low of −54 °F (−48 °C) occurred on Feb. 9, 1933, at Ukiah, and on Feb. 10, 1933, at Seneca. The highest temperature, 119 °F (48 °C), occurred at Prineville on July 29, 1898, and at Pendleton on Aug. 10, 1898.

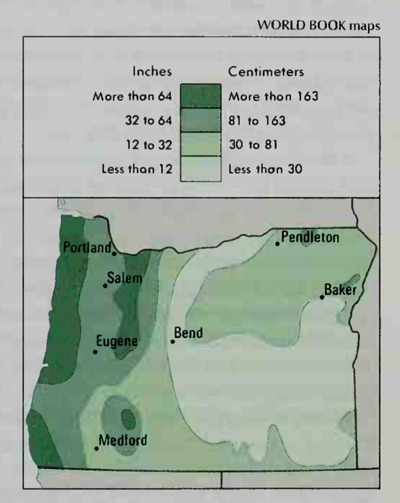
Average January temperatures

Moist, mild ocean winds give far western Oregon unusually mild winters for a state so far north.

Average July temperatures



The state has mild summers. The western and central sections are generally cooler than the rest of Oregon.

Average yearly precipitation

There are wide differences in precipitation throughout the state. The west gets heavy rains while the southeast is dry.

WORLD BOOK maps

Economy

Service industries, taken together, account for about two-thirds of Oregon's *gross state product*—the total value of all goods and services produced in a state in a year. However, manufacturing is the single most important industry in the state, accounting for about a fourth of the gross state product. The electronic products industry has grown to become the most important manufacturing activity in Oregon. Factories in the Portland area produce such high-technology products as computers, computer printers, and laboratory equipment. Wood processing, formerly the leading manufacturing activity, still plays a significant role. The economies of many Oregon cities rely almost entirely on this industry.

The Cascade Mountains divide Oregon into two major economic regions. Manufacturing and service industries are concentrated in the Willamette Valley in western Oregon. Western Oregon also produces large amounts of timber, milk, flower bulbs, seed crops, and vegetables. The dry lands east of the Cascades are most important for cattle, wheat, and potato production.

Millions of tourists visit Oregon. Tourism contributes over $5 billion annually to the state's economy.

Natural resources. Oregon's many natural resources include vital forest lands, small deposits of many minerals, and a plentiful water supply.

Forests. Oregon has almost a tenth of the nation's timber. Forests cover nearly half the state. Oregon has two forest regions: (1) the Douglas-fir region west of the Cascade Mountains, and (2) the ponderosa (western yellow) pine region east of the mountains.

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers Number of people	Percent of total
Manufacturing	25	264,000	13
Community, business, & personal services	17	591,800	29
Wholesale & retail trade	16	457,800	23
Finance, insurance, & real estate	15	144,700	7
Government	12	256,100	13
Transportation, communication, & utilities	7	89,500	4
Construction	5	118,100	6
Agriculture	3	105,400	5
Mining	†	3,200	†
Total	100	2,030,600	100

*GSP = gross state product, the total value of goods and services produced in a year.
†Less than one-half of 1 percent.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

The Douglas-fir, Oregon's state tree, provides the largest amount of timber. Ponderosa pine, western hemlock, western redcedar, Sitka spruce, and several kinds of true firs also grow in the Douglas-fir region. Some Douglas-fir trees grow in the ponderosa pine region, as do Engelmann spruce, western white pine, lodgepole pine, sugar pine, and true firs.

Minerals. Widespread deposits of limestone, sand, and gravel are Oregon's most important mined resources. Sand and gravel are found in almost all parts of the state. The most valuable limestone deposits are in northwestern and far eastern Oregon.

A small natural gas field lies beneath Columbia County in the northwestern part of the state. Diatomite, which is used to make filters, is found in east-central Oregon. The state also has deposits of clays, coal, gemstones, gold, nickel, silver, and talc.

Water is one of Oregon's most important resources. Melted snow and winter rain from the mountains feed Oregon's rivers and provide unusually pure water for industry and home use. The Columbia River and its tributaries provide water for power and irrigation.

Soils. Gray-brown soils cover the Coast Range and Klamath Mountains regions. The Willamette Lowland has deep, fertile soils. Shallow soils cover most of the eastern Cascade slopes, and the Basin and Range Region. The wheat belt of north-central Oregon has rich soils good for growing crops.

Service industries produce the largest portion of Oregon's gross state product. These services are concentrated in the metropolitan areas.

Oregon's leading service industry is community, business, and personal services. This industry group employs more people than any other economic activity in the state. Community, business, and personal services consists of a variety of businesses, including private health care, hotels and motels, law firms, engineering companies, and repair shops. Many of the hotels and motels are along the coast and in the Portland area.

Wholesale and retail trade is the second most important service industry in Oregon in terms of contributions to the gross state product. The Port of Portland handles much wholesale trade, including the import of foreign cars and the export of wheat and forest products. Nike, one of the world's major wholesale distributors of athletic shoes and other sportswear, is based in Beaverton. Major retail establishments include department stores and food stores.

Finance, insurance, and real estate ranks third among Oregon's service industries in terms of the gross state product. Real estate is important to the state's economy because of the large amounts of money involved in the buying and selling of homes and other property. The development of retirement villages and vacation resorts is an important part of real estate. Portland is the state's main financial center. U.S. Bancorp, one of the nation's major banking companies, has many offices in Oregon.

Government ranks next among the service industries. Government services include public schools and hospitals. The University of Oregon and Oregon State University employ many people in Eugene and Corvallis. The United States Forest Service, a federal government agency, also employs many people in the state. Oregon Health Sciences University in Portland is an important center of medical research. State government agencies are based in Salem, Oregon's capital.

Transportation, communication, and utilities rank fifth. Many shipping and trucking companies are based in Portland. Telephone companies are the major part of the communication sector. Pacificorp, the state's largest utility company, is based in Portland. This company is one of the nation's biggest providers of hydroelectric power. More information about transportation and communication appears later in this section.

Manufacturing. Products made in Oregon have a *value added by manufacture* of about $27 billion a year. This figure represents the increase in value of raw materials after they become finished products.

Electronic equipment is Oregon's leading product in terms of value added by manufacture. Many companies manufacture high-technology electronic products in the state. These products include oscilloscopes and computer monitors made by Tektronix, calculators and electronic printer components made by Hewlett-Packard, and microprocessors made by Intel Corporation.

Wood processing is the second most important manufacturing activity in the state. Oregon leads the states in lumber production. It is also a major producer of plywood, veneer, and particle board. Many parts of western Oregon have large wood-processing plants. As these plants have become more mechanized, employment in the wood products industry has declined.

Food processing ranks third among Oregon's manufacturing activities. Frozen fruits and vegetables are the leading products of this industry. Other foods produced in the state include baked goods, beverages, and canned goods.

Transportation products rank next. Important products from this sector include motor homes, ships and boats, and parts for motor vehicles and the aerospace industry.

Other goods produced in Oregon include machinery, paper products, printed materials, fabricated metal products, and primary metals. The Portland area is the

Economy of Oregon

This map shows the economic uses of land in Oregon and where the leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

- Mostly cropland
- Cropland mixed with grazing land and forest
- Mostly grazing land
- Forest land
- Mostly unproductive land

- Manufacturing center
- Mineral deposit

WORLD BOOK map

center of production for all of these goods. Oregon's factories produce machinery for the wood products and metalworking industries. St. Helens and West Linn have mills that make paper. Commercial print shops and newspaper publishers produce a majority of the printed materials. Fabricated metals industries produce tools, hardware, and other metal items. Primary metals industries include aluminum refineries, steel mills, and companies that make metal casts and extrusions.

Agriculture. Farmland covers about 30 percent of Oregon's land area. The state has about 40,000 farms.

Greenhouse and nursery products are the leading agricultural products in Oregon. Western Oregon is an important bulb-growing region. Farmers there grow daffodils, gladioli, irises, lilies, and tulips for bulbs.

Timber is the next most valuable agricultural product in Oregon. The most important timber trees are Douglas-fir and ponderosa pine. Douglas-fir trees grow mainly in the Cascade Mountains region and in smaller ranges west of the Cascades. Ponderosa pines grow primarily in the Blue Mountains of eastern Oregon. The state is a leading producer of Christmas trees.

Beef cattle and milk are also important agricultural products in Oregon. Most beef cattle are raised on ranges east of the Cascades. Western Oregon has many herds of dairy cattle.

Wheat is Oregon's most valuable food crop. Most wheat grows in the plateau region of north-central Oregon near Pendleton. Hay is Oregon's most important feed crop. Barley and oats are the state's other major grain crops.

Oregon ranks among the top states in vegetable production. Potatoes are the leading vegetable. Large potato crops are grown on irrigated land in the far eastern part of the state. Most of Oregon's other vegetables grow in the Willamette Valley, the state's most diverse agricultural region. These vegetables include green peas, onions, snap beans, and sweet corn. Other west-

Steve Terrill

A tulip farm near Monitor produces flower bulbs. Farmers in western Oregon also grow daffodils, gladioli, irises, and lilies for bulbs.

Steve Terrill

Loggers in a forest near Westport cut timber for Oregon's forest products industry. Wood processing is one of the state's leading manufacturing activities. Oregon ranks among the leading states in the manufacture of forest products.

ern Oregon crops include hops, which are used in making beer, and filberts (also called hazelnuts and cobnuts). The eastern part of the state produces large sugar beet crops.

Oregon is among the leading states in the production of berries, pears, plums, and sweet cherries. The Hood and Rogue river valleys are famous pear-growing regions. North-central Oregon leads the state in cherry production. Berries and plums are grown mainly in the northwestern part of the state. Apples are grown in the Hood River Valley.

Oregon farmers specialize in several crops that are not grown widely in many other states. For example, Oregon produces almost all the nation's seed for bentgrass, fescue, ryegrass, crimson clover, Kentucky and merion bluegrasses, and orchardgrass. These crops are grown mainly in Willamette Valley counties. Oregon is also a leader in the production of peppermint oil.

Douglas County, in southwestern Oregon, leads the state in sheep raising. Sheep also graze on the eastern ranges and the Willamette Valley grasslands. Willamette Valley farmers raise most of the state's chickens. Umatilla County is the leading hog producer.

Mining. Two mined products—(1) sand and gravel and (2) stone—provide about three-fourths of Oregon's mining income. These products, used mainly for road construction, are mined in several regions of the state. Oregon is a leading state in the production of pumice. Other products mined in Oregon include clays, diatomite, gold, and semiprecious gems.

Fishing industry. Oregon has an annual fish catch valued at about $70 million. Albacore tuna, crab, shrimp, and whiting are among the state's leading catches.

Electric power. Hydroelectric plants supply the vast majority of Oregon's electric power. Most of the state's hydroelectric power comes from dams that stand on the Columbia River between Oregon and Washington. They include Bonneville, John Day, McNary, and The Dalles. The rest of the state's hydroelectric power is generated at dams on rivers entirely within Oregon. These rivers include the Deschutes, Willamette, and Rogue. Oregon's large supply of hydroelectric power make its electric rates among the least expensive in the nation. Plants that burn coal or natural gas supply small amounts of the state's power.

Transportation. From 1841 to the coming of the railroads in the 1860's, thousands of people traveled the famous Oregon Trail to Oregon (see **Oregon Trail**). Today, Oregon has about 97,000 miles (156,000 kilometers) of roads. About 20 rail lines provide freight service. Passenger trains serve several Oregon cities.

Portland International Airport is one of the major airports in the western United States. Oregon's next busiest airports are in Eugene and Medford.

Portland is a major ocean port, though it is about 100 miles (160 kilometers) inland. Oceangoing ships follow a deepened channel up the Columbia and into the Willamette River to reach Portland's harbor. Oregon's other major ports are Coos Bay and Astoria.

Communication. Oregon's first newspaper, the *Oregon Spectator,* began publication at Oregon City in 1846. It is no longer published. *The Oregonian* was established in Portland in 1850 as the *Weekly Oregonian.* The *Oregon Statesman* (now the *Statesman Journal)* appeared in Oregon City in 1851 and later moved to Salem. These two papers are still published today. Other leading daily newspapers in Oregon include the *Mail Tribune* of Medford and *The Register-Guard* of Eugene. Oregon has about 120 newspapers, including about 20 daily newspapers. Oregon publishers also issue about 100 periodicals.

Oregon's first commercial radio station, KGW, opened in Portland in 1922. Its first television station, KPTV, began operating in Portland in 1952. Oregon has about 160 radio stations and 20 TV stations. Cable TV systems and Internet providers serve many communities statewide.

Constitution. The present state Constitution was adopted in 1857, two years before Oregon joined the Union. Constitutional amendments may be proposed by either house of the state legislature. A majority of the members of each house must approve the amendments. Voters must then approve the amendments in the next regular general election, unless the legislature orders a special election.

Amendments to the Constitution of Oregon may also be proposed and passed directly by the people, through their powers of *initiative and referendum* (see **Initiative and referendum**). The Constitution may also be revised by a constitutional convention. A convention may be called after a majority of legislators and voters give their approval.

Executive. Oregon voters elect the governor to a four-year term. The governor has the power to appoint members of many state boards and commissions. Other top state officials include the attorney general, commissioner of labor and industries, secretary of state, superintendent of public instruction, and treasurer. These officials are also elected to four-year terms.

Legislature is called the *Legislative Assembly*. It consists of a Senate of 30 members and a House of Representatives of 60 members. The state has 30 senatorial districts and 60 representative districts. Voters in each senatorial district elect one senator. Voters in each representative district elect one representative.

State senators serve four-year terms, and representatives serve two-year terms. The Assembly meets in regular session in odd-numbered years. Legislative sessions usually begin on the second Monday in January. There is no limit to a session's length.

Courts. The highest court in Oregon is the state Supreme Court. It has seven justices elected to six-year terms. The court elects one of its members to serve a six-year term as chief justice. The next highest state court is the court of appeals. It has 10 judges who are elected to six-year terms.

Oregon is divided into 19 judicial districts. Each judicial district has one or more circuit court judges. Voters elect the circuit court judges to six-year terms by *nonpartisan* (no-party) ballot.

A special tax court ranks with the circuit courts. Lower courts in Oregon include district, county, justice, and municipal courts.

Local government. Oregon gives its cities and towns *home rule*. This means they have the right to choose their own form of government. Most cities with more than 5,000 people have the council-manager form

The governors of Oregon

	Party	Term
John Whiteaker	Democratic	1859-1862
A. C. Gibbs	Republican	1862-1866
George L. Woods	Republican	1866-1870
La Fayette Grover	Democratic	1870-1877
Stephen F. Chadwick	Democratic	1877-1878
W. W. Thayer	Democratic	1878-1882

Bruce Berg

The Oregon House of Representatives meets in the State Capitol in Salem. Each of its 60 members is elected to a two-year term.

of government. Portland has a mayor and four commissioners. Most of Oregon's smaller cities have a mayor and a city council.

A 1958 amendment to the state Constitution extended home rule privileges to Oregon counties. However, only 8 of the state's 36 counties have taken action under this law. A three- or five-member board of commissioners governs most counties in Oregon. In most cases, the county commissioners are elected to four-year terms.

Revenue. Taxes account for about half of the state government's *general revenue* (income). Other sources of revenue include bond sales, charges for government services, and grants from the federal government. The most important source of tax revenue is a personal income tax. Other major sources of tax revenue are taxes on motor fuels, motor vehicle licenses, corporate income, and tobacco products. The state also receives revenue from a lottery. Oregon has no state sales tax.

Politics. The Republican Party controlled Oregon politics during most of the state's history. Many industrial workers who settled in Oregon cities after World War II caused changes in the state's politics. In the mid-1950's, registered Democrats began to outnumber registered Republicans.

The legislative districts have been changed periodically, beginning in the 1960's. These actions have given more representation to urban areas, where the Democrats have their greatest strength. Since the early 1970's, both Democratic and Republican candidates have won election to the highest state offices. For Oregon's voting record in presidential elections since 1860, see **Electoral College** (table).

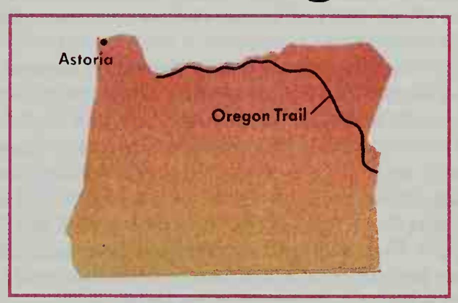
History

Indian days. When the first white people entered the Oregon region, many Indian tribes lived there. The Chinook lived along the lower Columbia River, where they fished for salmon. The Clackama, Kalapuya, Multnomah, and Tillamook tribes also made their homes in the northwest. The Bannock, Cayuse, Paiute, Umatilla, and a major band of the Nez Perce lived east of the Cascade Mountains. The Klamath and the Rogue lived near the present-day border with California.

Exploration and settlement. Spanish explorers sailing north from Mexico in 1543 were the first white people to see the Oregon coast. Sir Francis Drake of England may have seen Oregon's southern coast in 1579 while searching for a water route between the northern Pacific and Atlantic oceans.

In 1778, British explorer James Cook sailed to Yaquina Bay and named Cape Foulweather as he went north. In 1788, the first American ships arrived off the Oregon coast, including one led by Captain Robert Gray. In May 1792, Gray became the first to sail into the Columbia River, which he named for his ship. A few weeks later, Captain George Vancouver of Britain, who was exploring the Northwest coast, sent William Broughton, one of his lieutenants, into the Columbia. Broughton probably sailed as far as the Sandy River, east of present-day Portland, and named such landmarks as Mount Hood and Mount St. Helens. The explorers Meriwether Lewis and William Clark reached the mouth of the Columbia by land in 1805. The Lewis and Clark expedition, together with Gray's trip on the Columbia River, gave the United States a strong claim to the Oregon region.

In the early 1800's, the Oregon region stretched from Alaska, which was claimed by Russia, to California, which was claimed by Spain. It extended eastward from the Pacific Ocean to the Rocky Mountains. Russia, Spain, Britain, and the United States claimed parts of the region. Russia based its claims on Russian explorations along the northern Pacific Coast. In treaties with Britain and the United States in 1824 and 1825, Russia gave up its interests south of latitude 54° 40′. In 1819, by treaty, Spain gave up its claim north of latitude 42°, Oregon's present southern boundary. Britain and the United States could not agree on a boundary line. They signed a treaty in 1818 that permitted citizens of both countries to trade and settle in the region. The treaty was renewed in 1827.



John Jacob Astor, an American fur trader, began the white settlement of Oregon. His company, the Pacific Fur Company, set up a fur-trading post at Astoria in 1811. But the North West Company, a British fur company, gained possession of Astoria in 1813 during the War of 1812. In 1821, the company merged with the Hudson's Bay Company, another British trading firm. This firm founded Fort Vancouver (now Vancouver, Washington) in 1825. John McLoughlin guided the activities of the Hudson's Bay Company and ruled the region for about 20 years. He later became a U.S. citizen. McLoughlin played a leading part in settling the region. Today, he is known as the *father of Oregon.*

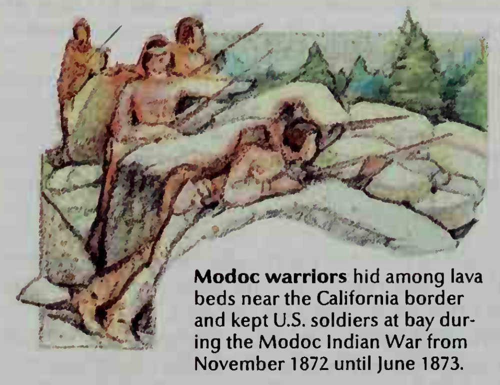
In 1834, Methodist missionaries established the first permanent American settlement in the Willamette Valley. The first large overland migration into Oregon came in 1843. That year, about 900 people traveled the Oregon Trail and settled in the Willamette Valley. Hundreds of American settlers arrived each year from then on. The increasing number of settlers put pressure on the U.S. government to settle the boundary dispute with Britain. In 1844, James K. Polk based his campaign for the presidency partly on the claim that land south of latitude 54° 40′ belonged to the United States (see **Fifty-Four Forty or Fight**). In 1846, President Polk signed a treaty with Britain. It fixed the 49th parallel as the chief dividing line between United States and British territory.

Indian wars. In 1847, Indians massacred Marcus Whitman and 13 others, near present-day Walla Walla, Washington (see **Whitman, Marcus**). This massacre led to the Cayuse War of 1847-1848. It also resulted in the execution in 1850 of five Cayuse Indians held responsible for the massacre. The discovery of gold in southwest Oregon during the early 1850's led to a series of conflicts between white miners and the Rogue Indians. The resulting Rogue River Indian War ended in 1856 with the removal of the Indians to a reservation on the central coast of Oregon.

One of the major Indian wars, the Modoc War, lasted from November 1872 to May 1873. The U.S. government

Historic Oregon

Captain Robert Gray visited the Oregon country in 1792. He sailed into the mouth of a great river that he named after his ship, the *Columbia.*



Settlers traveled west on the Oregon Trail from Independence, Mo., to the Willamette Valley during the 1840's. The Oregon Territory was created in 1848.

Astoria was founded by John Jacob Astor's Pacific Fur Company in 1811. The fur-trading post was the first white settlement in the Oregon region.

John McLoughlin, the director of the Hudson's Bay Company in the Oregon region from 1824 to 1846, helped many settlers. He is known as the *father of Oregon.*

Modoc warriors hid among lava beds near the California border and kept U.S. soldiers at bay during the Modoc Indian War from November 1872 until June 1873.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Oregon

1579 Sir Francis Drake possibly touched the Oregon coast.

1792 Robert Gray sailed into the Columbia River.

1805 Meriwether Lewis and William Clark reached the mouth of the Columbia.

1811 John Jacob Astor founded Astoria.

1819 A treaty between the United States and Spain fixed the present southern border of Oregon.

1843 The Willamette settlers at Champoeg organized a provisional government.

1846 A treaty made the 49th parallel the chief boundary between British and U.S. territory in the Oregon region.

1848 Oregon became a territory.

1850 Congress passed the Oregon Donation Land Law.

1859 Oregon became the 33rd state on February 14.

1902 Oregon adopted the initiative and referendum.

1912 The state adopted woman suffrage.

1937 Bonneville Dam was completed.

1950's McNary and The Dalles dams were built on the Columbia River.

1964 Heavy floods damaged western Oregon.

1982 Construction was completed on a second powerhouse at Bonneville Dam.

1991 Barbara Roberts became Oregon's first woman governor. She held office until 1995.

forced the Modoc Indians onto the Klamath Reservation. But the Modoc fled from the reservation and hid near the California border among lava beds, which provided a natural fortress. A small band of warriors kept more than a thousand U.S. soldiers at bay until the Indians finally surrendered.

The Nez Perce War occurred in 1877. That year, the government ordered several Nez Perce bands to move from their traditional lands in the beautiful Wallowa Valley and other areas to a reservation in Idaho. Some bands resisted. One group, led by Chief Joseph, tried to escape through Idaho and Montana. Joseph and over 400 Nez Perce finally surrendered near the Canadian border. The Paiute and Bannock Indians rose against Oregon settlers in 1878, but were quickly defeated. See **Indian wars** (In California and the Northwest).

Provisional and territorial governments. In 1843, settlers in the Willamette Valley met at Champoeg (near present-day Newberg) and organized a provisional government. The settlers adopted a set of laws which were based on the laws of Iowa.

Oregon became a territory in 1848, and Oregon City was proclaimed the territorial capital in early 1849. The legislature moved to Salem in 1851. Oregon's present boundaries were drawn in 1853, when Congress created the Washington Territory.

The Donation Land Law of 1850 spurred territorial growth and development. This law provided that any male American citizen over 18 who settled in Oregon before December 1850 could receive 320 acres (129 hectares) of land. His wife could also receive 320 acres of her own. To qualify for ownership, a man had to cultivate his claim for four years. From December 1850 to December 1855, a settler had to be at least 21 to receive land, and he got only 160 acres (65 hectares). A settler's wife could receive the same amount.

Progress as a state. Oregon joined the Union as the 33rd state on Feb. 14, 1859. Salem became the state capital. During the Civil War (1861-1865), state volunteers protected eastern Oregon against Indian attacks. The attacks continued for 15 years after the war. The population increased rapidly after the war as former soldiers sought opportunities in the West. The population grew from about 52,000 in 1860 to over 300,000 by 1890. Much of this increase occurred during the 1880's after the arrival of the transcontinental railroads.

The early 1900's. In 1902, Oregon adopted the *initiative and referendum,* procedures that permit voters to take a direct part in lawmaking (see **Initiative and referendum**). In 1908, it adopted the *recall,* a procedure for removing undesirable officials from office. The use of these direct-government procedures became known as the *Oregon system.* Many states have passed initiative, referendum, and recall laws based on this system.

In 1912, Oregon gave women the right to vote for the first time in the state's history. Passage of the law followed a long and difficult campaign for women's rights led by Abigail Jane Scott Duniway.

During the Great Depression of the 1930's, the federal government provided money to build Bonneville Dam on the Columbia River. The dam and nearby locks supplied electric power for industry and improved the river for navigation. Owyhee Dam, which was completed in 1932, provided irrigation water for vast areas of farmland in the Owyhee and Snake river valleys.

Oregon Historical Society

Bonneville Dam, built with federal funds, made the Columbia River navigable and supplies electric power for industry. This picture shows construction on the dam in the mid-1930's.

The mid-1900's. By 1940, Oregon's population had grown to more than a million. During World War II (1939-1945), many of the state's factories produced military equipment. Portland became a major port for shipment of supplies to the Soviet Union and to U.S. armed forces in the Pacific. The city's shipyards produced cargo vessels and warships. Thousands of people from other states came to work in Oregon defense plants, and many of them settled in the state after the war.

During the 1950's, McNary and The Dalles dams were built on the Columbia River and greatly increased Oregon's supply of low-cost electric power. In 1956, pipelines brought natural gas into the state. Both developments contributed greatly to Oregon's industrial growth. Many people began to move from rural to urban areas to take manufacturing jobs.

Important changes took place in the Oregon timber industry during the 1960's. In the past, sawdust, bark, and other logging by-products had been wasted. Now, Oregon companies began to use many of these materials to make hardboard, pulp, and other wood products. Forestry specialists discovered new uses for forest products and studied ways to conserve the state's timber reserves. The industry replanted an increasing number of trees to replace those that had been cut down.

Changes also occurred in Oregon agriculture. The state's farms became larger and more closely linked with food processing. Farmers used more and more machinery. Irrigation projects allowed farmers to grow fruits and vegetables on land that once had been too dry for any crops except grasses.

Low-cost hydroelectric power from dams on the Columbia and Willamette rivers helped Oregon's economy grow during the 1960's. Industries, including the manufacture of electrical equipment, machinery, and metals, grew in importance.

The worst floods in Oregon's history hit in 1964. They caused millions of dollars of damage, killed several people, and forced thousands from their homes.

The late 1900's. Completion of a number of dams on the Columbia and Snake rivers in the early 1970's provided deepwater transportation from the mouth of the Columbia to Lewiston, Idaho. These dams also increased the hydroelectric power capacity in Oregon. The power output of Bonneville Dam, the first federal dam constructed on the Columbia River, was more than doubled in 1982 when construction of a second powerhouse was completed.

In the early 1980's, Oregon experienced its worst economic crisis since the Great Depression. A widespread decline in housing and construction led to hard times in the lumber, wood processing, and construction industries. Many Oregon lumber mills closed, and many jobs were lost in the wood and construction industries. Low prices for farm products, including wheat and dairy and livestock products, contributed to the crisis.

Improvements in Oregon's economy began in the mid-1980's and continued in the 1990's. Some of the lumber mills that had closed reopened. The electronics industry became important, although employment in trade and other service industries grew more rapidly than jobs in manufacturing. Expansion of the fruit, grass seed, nursery, nut, and wine industries also improved economic conditions.

In 1991, Barbara Roberts became Oregon's first woman governor. She served until 1995.

Oregon, University of, is a state-assisted coeducational school in Eugene, Oregon. The university has a college of arts and sciences; professional schools of architecture and allied arts, business administration, education, human development and performance, journalism, law, and music; and a graduate school. It also has interdisciplinary programs in the natural sciences, international affairs, and environmental affairs. Programs of study lead to bachelor's, master's, and doctor's degrees. The university has museums of art and of natural history. The University of Oregon was chartered in 1872 and opened to students in 1876.

Critically reviewed by the University of Oregon

Oregon grape is the state flower of Oregon. This wild plant, also called the *Oregon holly grape,* grows from western Oregon through Washington into British Columbia. Despite its names, the Oregon grape is neither a grape nor a holly. It grows to 2 feet (61 centimeters) tall and does not climb as the wild grape does. The leaves look like those of the holly, and the wood is yellow. Clusters of yellow flowers open in early summer. The

berries ripen in the fall. They look like grapes or blueberries and are often used for jelly. See also **Barberry**; Oregon (picture: State flower). Fred T. Davies, Jr.

Scientific classification. The Oregon grape is in the barberry family, Berberidaceae. Its scientific name is *Mahonia nervosa.*

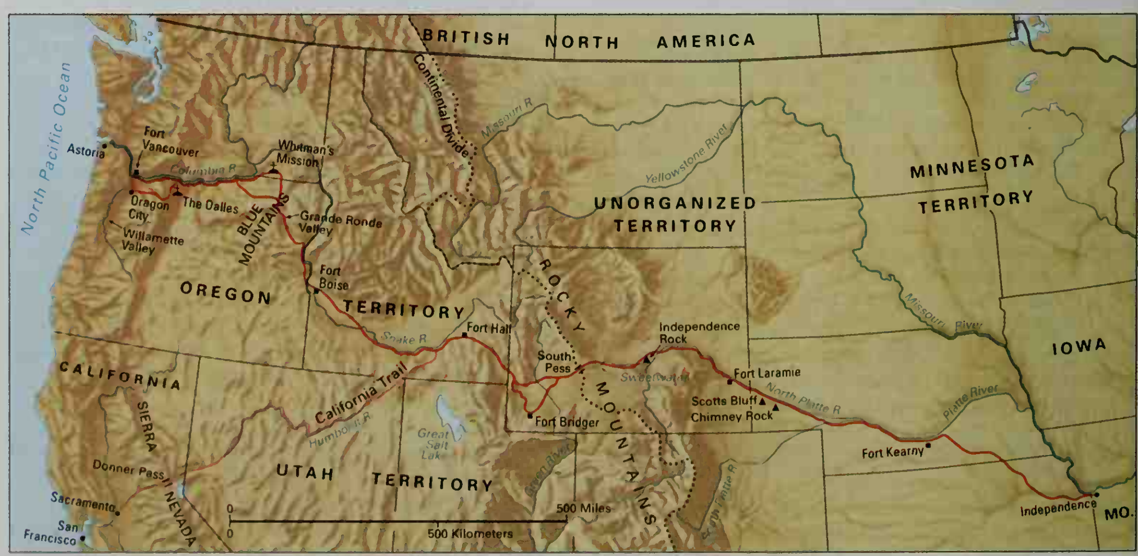
Oregon State University is a state-supported, coeducational school in Corvallis, Oregon. It includes colleges of agricultural sciences, business, engineering, forestry, health and human performance, home economics, liberal arts, oceanography, pharmacy, science, and veterinary medicine. It grants bachelor's, master's, and doctor's degrees. The university operates an extension service and agricultural experiment stations. It also has research vessels and a marine science center in Newport, Oregon. The school was founded in 1868.

Critically reviewed by Oregon State University

Oregon Territory was created after the settlement in 1846 of a boundary dispute between the United States and the United Kingdom. It included the present states of Idaho, Oregon, and Washington and part of Montana and Wyoming. Before 1846, the Oregon Country, occupied jointly by the United States and the United Kingdom, included the area south of Alaska, north of California, and west of the Rocky Mountains. The 1846 settlement gave the United States the land south of the 49th parallel, except for Vancouver Island. The Oregon Country became a territory in 1848. Oregon was admitted to the Union on Feb. 14, 1859. Jerome O. Steffen

Oregon Trail was the longest of the great overland routes used in the westward expansion of the United States. It wound 2,000 miles (3,200 kilometers) through prairies and deserts and across mountains from Independence, Missouri, to the Pacific Northwest. Even today, travelers can see the deeply rutted road cut by wagon wheels along sections of the trail.

Families traveling to the Oregon region usually began their journey at Independence, near the Missouri River. They followed a trail that ran northwest to Fort Kearny, Nebraska. Then they traveled up the Platte River and its north branch to Fort Laramie, Wyoming. From this point, they continued along the North Platte to its Sweetwater branch, and crossed through South Pass in the Rocky Mountains to the Green River Valley at Fort Bridger, Wyoming. The route turned northwest to Fort Hall in the Snake River area, and on to Fort Boise, Idaho. Settlers crossed the Grande Ronde Valley and the Blue Mountains to Marcus Whitman's mission at Walla Walla, Washington. Then they went down the Columbia River to Fort Vancouver and the Willamette Valley of Oregon.



Travel on the Oregon Trail was a severe test of strength and endurance. The journey in a covered wagon took six months. Settlers often had to cross flooded rivers. Indians attacked the wagon trains, and cholera and other diseases were common. Food, water, and wood were always scarce, and the travelers often encountered contaminated water holes.

Explorers and fur traders first traced the course of the Oregon Trail. In 1805, Meriwether Lewis and William Clark traveled on a western section of the route in the region of the Snake and Columbia rivers. Traders returning from Astoria also used the trail. Benjamin Bonneville is credited with taking the first wagons through South Pass in the 1830's. Nathaniel J. Wyeth also led companies over the trail. John C. Frémont surveyed a portion of the route in 1842 for the United States Army.

Settlers began following the trail to Oregon in 1841. The first large group, about 900, used the trail in the "Great Migration" of 1843. In that year, a provisional government was organized. The Oregon Country's northern boundary was set in 1846, and the Territory of Oregon was set up in 1848. W. Turrentine Jackson

WORLD BOOK map

The Oregon Trail was the chief route to the Northwest in the mid-1800's. Thousands of pioneers traveled along the trail from Independence, Missouri, to the Pacific Northwest. Other pioneers, attracted by gold in California, turned off near Fort Hall and followed the California Trail.

O'Reilly, Leonora (1870-1927), was an American labor leader and reformer. She became well known as a lecturer and union organizer. O'Reilly strongly supported vocational training for girls.

O'Reilly was born in New York City and went to work in a shirt collar factory at the age of 11. In 1897, she helped organize a local garment workers' union. From 1902 until 1909, O'Reilly taught at the Manhattan Trade School for Girls, where she developed a strong belief in vocational education.

In 1903, O'Reilly helped establish the National Women's Trade Union League. This group promoted laws to protect the rights of women factory workers and aided the growth of women's labor unions. In 1909, O'Reilly helped lead a strike in New York City by the International Ladies' Garment Workers' Union. Thousands of workers won wage increases after the five-month strike.

O'Reilly helped found the National Association for the Advancement of Colored People (NAACP) in 1909. She also was active in the Woman Suffrage Party and the Socialist Party. Charles Shively

Orellana, *OH ray LYAH nah,* **Francisco de** (1511?-1546), a Spanish explorer, headed the first group of Europeans to navigate the entire length of the Amazon River in South America. In March 1541, he joined a Spanish expedition traveling eastward from Quito in what is now Ecuador. The expedition was led by Gonzalo Pizarro, a half brother of the Spanish explorer and conqueror Francisco Pizarro. The Spaniards soon began to starve and become sick. In December 1541, Orellana and about 55 other men set out by boat on a tributary of the Amazon River in search of food, but they never returned. Instead, they sailed to the Atlantic Ocean, which they reached in August 1542. Some historians consider Orellana a traitor for abandoning Pizarro. In 1544, Orellana was named governor of the territory he had explored. See **Amazon River** (History). Helen Delpar

Orestes. See Electra; Iphigenia.

Orff, Carl (1895-1982), was a German composer and music educator. His major works were for the stage. They combine instrumental music, singing, and gesture and dance into a unified spectacle. Orff's music emphasizes simple, folklike melodies and harmonies that are sometimes colored with dissonance. He used instruments percussively to create a powerful rhythmic drive. Orff used Oriental and medieval scales and texts in several languages, sometimes simultaneously.

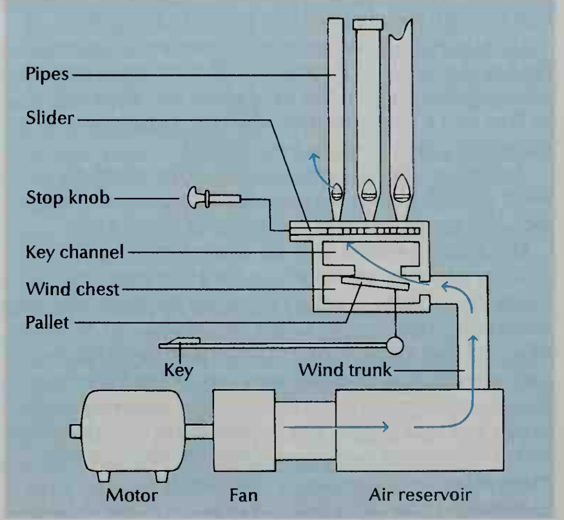
Orff's best known compositions are three pieces he called *Trionfi (triumphs).* The first, and most popular, *Carmina Burana* (*Songs of Beuron,* 1937), consists of songs set to medieval texts. He used poems by the Roman poet Catullus as texts in *Catulli Carmina* (*Songs of Catullus,* 1943). In *Trionfo di Afrodite* (*The Triumph of Aphrodite,* 1953), Orff adapted texts by Catullus and the ancient Greek writers Sappho and Euripides.

Orff was born in Munich. In 1924, he cofounded a school of gymnastics, music, and dance in Munich. His work at the school reflected his interest in musical education for children. Orff summed up his theories in an important five-volume book called *Music for Children* (1930-1934, revised 1950-1954). Daniel T. Politoske

Organ. See Human body.

Organ is a keyboard musical instrument. There are two chief kinds of organs, *pipe organs* and *electronic organs.* Most pipe organs are found in churches, concert halls, and theaters. The history of the pipe organ can be traced back more than 2,000 years. Many masterpieces of music have been composed for it.

The electronic organ was invented in the mid-1900's. Most performers consider the pipe organ superior to the electronic organ. However, electronic organs are popular instruments in the home, and many churches also have them. The electronic organ ranks behind only the piano and the guitar as the most widely played instrument in the United States.



Both the pipe organ and the electronic organ have one or more keyboards that resemble a piano keyboard. However, the instruments produce sounds differently. A piano makes sounds by causing steel strings to vibrate. A pipe organ creates sounds by forcing air through metal or wooden tubes called *pipes.* An electronic organ produces sounds by means of electricity.

A pipe organ is the largest and most powerful of all musical instruments. Many pipe organs are so large that they must be built as part of the building where they are to be used. A large pipe organ can produce effects of grandeur that even a symphony orchestra cannot duplicate. It also can play delicate and refined music.

Pipe organs. A small pipe organ has only a few hundred pipes, but a large organ has more than 5,000 pipes. Most pipes are made of lead or of lead mixed with tin. Some are made of other metals or wood.

An organist creates music by combining the sounds of different *ranks* (rows) of individual pipes. Each pipe in a rank is tuned to a single pitch and produces only one musical tone. Some ranks are pitched one or two octaves higher or lower than others.

How a pipe organ works

WORLD BOOK diagram by Art Grebetz

This diagram shows how wind flows through a pipe organ. An electric motor provides power for most modern organs. It operates a fan that forces wind into an air reservoir. The wind moves through a wind trunk into a wind chest. When a key is pressed, za pallet opens and wind enters the key channel. From there a slider, controlled by a stop knob, allows wind to flow into the pipes. As the wind passes through a pipe, it produces a note.

Most organs have two types of pipes—*flue pipes* and *reed pipes.* A flue pipe works like a simple whistle. Air enters from a hole in the bottom of the pipe and causes a column of air inside the pipe to vibrate. The vibration creates the sound. A reed pipe contains a thin brass reed that vibrates as air passes around it.

About 80 percent of the pipes in an organ are shaped like cylinders. But no two pipes of an organ look or sound exactly alike. The shape and size of the pipe determines the sound it makes. The longest pipes, which produce the lowest notes, may be more than 30 feet (9 meters) long and 1 foot (30 centimeters) in diameter. But most pipes measure less than 4 feet (1.2 meters) long. The smallest pipes, which produce the highest notes, are only 7 inches (18 centimeters) long and less than $\frac{1}{4}$ inch (6 millimeters) in diameter.

Most pipe organs have one, two, or three keyboards. A few have as many as six. The additional keyboards enable the organist to create a wide variety of musical effects. The keyboards played with the hands are called *manuals.* Large organs may have up to five manuals called, in order of importance, the *great organ; swell organ; positive,* or *choir, organ; solo organ;* and *echo organ.* Most organs also have a *pedalboard,* a keyboard played with the feet. Each keyboard—manuals and pedalboard—operates a number of ranks. Every key controls several pipes. All the ranks operated by a keyboard are arranged on a *wind chest,* a box that receives an even flow of *wind* (air) from a reservoir. An electrically powered fan fills the reservoir with wind.

A thin strip of plastic or wood called a *slider* lies under each rank of pipes on a wind chest. A slider has holes in it that match the number and size of the holes in the rank of pipes above it. A slider regulates the passage of wind into the pipes. Sliders are controlled by *stop knobs,* commonly called *stops,* near the manuals. By pulling a stop, the organist moves the slider into position beneath the pipes so that wind can enter them.

To let wind into certain pipes, the organist presses the key that controls those pipes. This action opens a valve called a *pallet* in the wind chest and allows wind to flow into a compartment called the *key channel.* Wind enters the pipes from the key channel.

A cabinet called a *case* encloses all the pipes on a wind chest. It blends the sounds of the pipes and projects this combination of sound out of the organ.

Electronic organs have no pipes. Devices called *oscillators* generate an electric current that produces the tones. The organ's sound is amplified electronically. An electronic organ cannot create the variety and richness of sound that a pipe organ can. But it costs less and requires less space. The electronic organ has become a popular instrument in the home. It also is widely used in jazz and rock music. The *synthesizer* is a modern keyboard instrument capable of imitating the sounds of many other instruments. See **Synthesizer.**

History. In the 200's B.C., Ctesibius of Alexandria, a Greek engineer, built an organ that was called a *hydraulis,* or *hydraulus.* This organ used water power to force air into the pipes. Organs that used a bellows first appeared in Byzantium (now Istanbul, Turkey) during the A.D. 100's and 200's. The major features of the modern organ were developed from the 200's to the 1500's. The keyboard was developed by the end of the 1400's.

From the 1500's to the mid-1700's, many composers wrote organ masterpieces. The greatest of these composers was Johann Sebastian Bach of Germany. Other leading organ composers included François Couperin of France and Girolamo Frescobaldi of Italy. During this period, organists accompanied singers in operas and in oratorios. Large organs were played in churches. Small organs were popular at home and at public events.

By the late 1700's, small organs had lost their popularity. Many composers believed an orchestra or a piano could provide a wider range of musical effects. By 1900, interest in the organ had declined among composers and performers. The instrument was played regularly only in churches as part of religious services.

A revival of interest in the organ began during the early 1900's. The German humanitarian Albert Schweitzer, an accomplished organist, began this revival. He gave concerts in many European cities and stimulated interest in the instrument. In 1934, Laurens Hammond, an American inventor, patented the first commercially practical electronic organ. Dale C. Carr

Organ donation is the process through which human organs are obtained for transplant surgery. Most organs used in transplant operations come from young, otherwise healthy patients who suffer *brain death* (a permanent end of brain function), often following a fatal head injury. Organs commonly transplanted from one person to another include the heart, kidney, liver, and lung.

Advances in organ transplant surgery and powerful drugs to prevent organ rejection have made transplants an established medical treatment for many diseases and injuries. Organ donation can save lives and restore health, and most major religions permit such donations. The supply of human organs falls far short of the demand, however. As a result, medical professionals must make difficult ethical decisions to obtain human organs and assign them to people in need of transplants.

In most countries, doctors must obtain permission to remove organs from the dead to use for transplant. In the United States and the United Kingdom, people can use donor cards or mark a space on their driver's license to give permission to donate their organs after death. In practice, however, many hospitals consult the family even if the patient has signed an organ donor card. In Australia, donor permission is required, but final approval must come from family. In some other countries, including Austria and Belgium, doctors may remove organs for transplant after death unless there is written evidence that the person does not want to be a donor. This system, called *presumed consent,* increases the supply of human organs available for transplant. But under such a system, some people who would not want to donate their organs might become donors.

Medical professionals are investigating ways to increase the supply of human organs for transplant, including increasing live donation and compensation for organ donors. More than one-third of transplanted kidneys in the United States come from live donors, because a person can donate one kidney and remain

healthy. Live liver donation, where a lobe of the donor's liver is transplanted and grows into a fully functioning organ, is also becoming more common. Most living organ donors are close relatives of the recipient, but about 20 percent of live organ donations involve unrelated people.

In the United States, the National Organ Transplant Act of 1984 prohibits the exchange of organs for any kind of payment. However, lawmakers are considering legislation that allows compensation to donors to encourage more live organ donations. Arlene J. Klotzko

Organic chemistry is the study of compounds that contain carbon atoms. Carbon atoms are unusual because they can form chemical bonds in many different ways, both with other carbon atoms and with other chemical elements. As a result, many kinds of carbon-containing compounds are possible. Scientists have identified several million organic compounds.

A large number of simple organic compounds are obtained from plant and animal sources. For example, petroleum and natural gas contain many hydrocarbons from the remains of organisms that lived millions of years ago. Ethanol, a kind of alcohol, is formed by the fermentation of fruits, grains, and vegetables. Other organic compounds in living matter include amino acids, sugars, and nucleic acids. Inorganic compounds, which generally do not contain carbon, occur chiefly in rocks and in minerals.

Scientists once believed that carbon-containing compounds could be obtained only from living sources. However, in 1828, the German chemist Friedrich Wöhler prepared the organic compound urea in his laboratory. Since then, scientists have found many ways of making organic compounds from both organic and inorganic materials, and many important new compounds have been prepared in the laboratory. These compounds include medicines, insecticides, and chains of molecules called *polymers* (see **Polymer**). Robert C. Gadwood

Organization for Economic Cooperation and Development is an association of 30 nations in Europe, North America, and the Pacific area. The organization, called the OECD, works to promote the economic and social welfare of its members, and coordinates their efforts to aid developing countries. The OECD was established in 1961 to succeed the Organization for European Economic Cooperation (OEEC). Seventeen European nations formed the OEEC in 1948 as a result of the Marshall Plan. Under the Marshall Plan, the United States helped Europe achieve economic recovery after World War II (1939-1945). The OECD's headquarters are located in Paris. See also **International Energy Agency.**

Critically reviewed by the Organization for Economic Cooperation and Development

Members of the OECD

Countries that became members of the OECD in 1961 do not have dates after their names. Other nations are listed with their years of admission.

Australia (1971)	Hungary (1996)	Norway
Austria	Iceland	Poland (1996)
Belgium	Ireland	Portugal
Canada	Italy	Slovakia (2000)
Czech Republic (1995)	Japan (1964)	Spain
Denmark	Korea, South (1996)	Sweden
Finland (1969)	Luxembourg	Switzerland
France	Mexico (1994)	Turkey
Germany	Netherlands	United Kingdom
Greece	New Zealand (1973)	United States

Organization for Security and Cooperation in Europe is an international association of more than 50 Eastern and Western countries that work to increase their security. The organization is sometimes called the OSCE. Until 1995, it was called the Conference on Security and Cooperation in Europe (CSCE).

The OSCE's members are Russia and all the other nations of Europe, plus the United States, Canada, and the central Asian countries that were once part of the Soviet Union. Members include all countries of the North Atlantic Treaty Organization (NATO) as well as the lands that once belonged to the Warsaw Pact. NATO is a non-Communist defense alliance, and the Warsaw Pact was a Communist one. The two alliances were intense rivals during the Cold War, a period of hostility that developed between the Communist and non-Communist nations after World War II ended in 1945. The Warsaw Pact, led by the Soviet Union, was dissolved in 1991.

The first of many CSCE conferences met in 1975 in Helsinki, Finland. That conference produced the Helsinki Accords. In the accords, Western countries finally recognized Eastern European boundaries that had been set up after World War II. The accords also stimulated the formation of human rights groups that later helped overthrow many Communist governments in Eastern Europe and the Soviet Union. In 1990, a CSCE conference in Paris declared an end to the Cold War. The Paris conference also established a CSCE secretariat in Prague, in what is now the Czech Republic; a conflict-resolution center in Vienna, Austria; and in Warsaw, Poland, an office to monitor elections in European countries.

The Soviet Union belonged to the CSCE until 1991, when the country broke up into a number of independent states. After the breakup, Russia assumed the Soviet seat, and all the other states that had been part of the Soviet Union eventually joined the CSCE.

In 1992, the CSCE acquired the authority to send peacekeeping forces to its member nations. It also agreed to oversee the negotiation of arms-control agreements between its Eastern and Western members.

Joseph Preston Baratta

Organization of African Unity (OAU) was an association of African states. It existed from 1963 until 2002, when it was replaced by the African Union (see **African Union**). The OAU played a large role in helping end colonial and white minority rule throughout Africa. It also worked to strengthen cultural, economic, military, and scientific ties among African peoples.

The OAU was founded in 1963 in Addis Ababa, Ethiopia, with 32 members. Its membership grew to include 52 countries and a government-in-exile. The OAU settled several boundary disputes between African states. It helped support national independence movements in countries such as Mozambique and Angola, as well as movements to end white minority control of Rhodesia (now Zimbabwe) and South Africa. It supported ambitious programs for economic development and cooper-

ation throughout Africa. The OAU also worked to increase Africa's influence in world affairs.

Despite its accomplishments, the OAU experienced many problems. For example, Morocco and other countries disputed the decision to admit the Saharawi Arab Democratic Republic (SADR) as an OAU member in 1982. The SADR is a government-in-exile that was formed by people seeking independence for Western Sahara, a territory claimed by Morocco. When the SADR took its seat in 1984, Morocco withdrew from the OAU. The organization's other problems included the failure of many countries to pay dues on time and difficulties in coping with armed conflicts between and within countries. In addition, larger countries often pursued their own interests rather than the interests of the OAU.

In 2000, OAU leaders signed an act creating an African Union, with a structure similar to that of the European Union (see **European Union**). The African Union officially replaced the OAU in 2002. The union's purpose is to continue the political and economic integration of Africa that was begun by the OAU. Mammo Muchie

See also **African Union**.

Organization of American States (OAS) is an association of 35 American countries. It seeks to provide for collective self-defense, regional cooperation, and the peaceful settlement of controversies. The OAS charter sets forth the group's guiding principles. These principles include a belief in the value of international law, social justice, economic cooperation, and the equality of all people. The OAS charter also states that an act of aggression against one American nation is regarded as an act of aggression against all the nations in the OAS.

The OAS functions through several bodies. Major policies are formed at annual sessions of the General Assembly. All member nations can attend, and each has one vote. Special Meetings of Consultation of Ministers of Foreign Affairs deal with urgent problems, especially those relating to defense or the maintenance of peace in the Americas. The Permanent Council, with headquarters in Washington, D.C., is the executive body of the OAS. Each member nation is represented. For convenience, diplomatic representatives in Washington serve as council members. The council supervises the General Secretariat, makes plans for General Assembly sessions, and oversees OAS administration. The secretary-general, the chief administrator of the OAS, is elected to a five-year term by the General Assembly. Specialized conferences promote inter-American cooperation.

The Organization of American States had its early beginning at the First International Conference of American States, which met in Washington, D.C., in 1889 and 1890. The delegates established the International Union of American Republics, with the Commercial Bureau of the American Republics as its central office. This bureau was renamed the Pan American Union in 1910. The Pan American Union became the permanent body of the OAS when it was organized in 1948 at the ninth Pan-American Conference, held in Bogotá, Colombia. The organization's original charter became effective in December 1951. An amended charter took effect in February 1970, and the Pan American Union was renamed the General Secretariat of the OAS.

Early in 1962, the Organization of American States voted to exclude Cuba's Communist government from active membership. But Cuba itself remains an OAS member even though its government cannot participate in any of the organization's activities.

Members of the OAS

Countries are listed with the years they became OAS members.

Antigua and Barbuda (1981)	Dominican Republic (1949)	Peru (1952)
Argentina (1956)	Ecuador (1950)	St. Kitts and Nevis (1984)
Bahamas (1982)	El Salvador (1950)	St. Lucia (1979)
Barbados (1967)	Grenada (1975)	St. Vincent and the Grenadines (1981)
Belize (1991)	Guatemala (1955)	Suriname (1977)
Bolivia (1950)	Guyana (1991)	Trinidad and Tobago (1967)
Brazil (1950)	Haiti (1950)	United States (1951)
Canada (1990)	Honduras (1950)	Uruguay (1955)
Chile (1953)	Jamaica (1969)	Venezuela (1951)
Colombia (1951)	Mexico (1948)	
Costa Rica (1948)	Nicaragua (1950)	
Cuba (1952)	Panama (1951)	
Dominica (1979)	Paraguay (1950)	

In 1965, a revolt in the Dominican Republic led the OAS to set up its first military force. Troops from six Latin American countries and the United States took part. The troops and OAS committees worked to restore order in the Dominican Republic. In 1969, the OAS acted quickly to end a five-day invasion of Honduras by troops from El Salvador.

During the late 1970's, the organization's main concern became human rights. The Inter-American Human Rights Commission—a specialized OAS agency—interviewed political exiles and conducted on-site investigations of human-rights violations. The commission also issued reports about electoral fraud, illegal imprisonment, and torture and other acts of brutality.

The influence of the OAS began to decline during the early 1980's because of increased involvement by other international agencies in Latin American affairs. These agencies included the International Monetary Fund and the World Bank. George W. Grayson

Organization of the Petroleum Exporting Countries (OPEC) is an association of 11 nations that depend heavily on oil exports for their incomes. Its members work together to try to increase their revenue from the sale of oil on the world market. OPEC members produce about 40 percent of the world's oil and possess about 75 percent of the world's recoverable oil reserves. The members of OPEC are Algeria, Indonesia, Iran, Iraq, Kuwait, Libya, Nigeria, Qatar, Saudi Arabia, the United Arab Emirates, and Venezuela.

OPEC was founded in 1960 by Iran, Iraq, Kuwait, Saudi Arabia, and Venezuela. At that time, the petroleum industry in these countries was controlled by United States and European oil companies. These firms paid the host governments income taxes and *royalties* (shares of their profits) based on the *posted price* the companies charged for crude oil on the world market. In 1959 and 1960, oil production greatly exceeded world demand. The surplus that was thereby created prompted several of the major companies to cut the posted price and thus their payments to host governments. OPEC was founded in response to this price cut.

OPEC had little influence on oil prices during the 1960's, when production expanded to keep pace with

demand. In the 1970's, however, world demand for oil began to outgrow what was available from non-OPEC sources. In 1973, OPEC stopped consulting with oil companies and decided to raise oil prices in keeping with the rate of *inflation* (the rise of all prices).

Armed conflict also contributed to rising oil prices. During the Arab-Israeli War of 1973, some Arab members of OPEC stopped or reduced oil exports to countries supporting Israel. As a result, oil prices in those countries, including the United States and other Western industrial nations, rose sharply. During the late 1970's, the Iranian revolution caused a shortage that helped OPEC increase oil prices again.

OPEC was less successful at achieving its goals in the 1980's, when the world oil supply again exceeded demand. In 1983, OPEC cut the price of its oil for the first time. During the middle and late 1980's, OPEC set production limits for its members several times. But many members ignored the limits, thereby holding prices down. Brief price increases resulted from Iraq's invasion of Kuwait in 1990, but since that time, oil prices have remained fairly stable. Bob Williams

Orient is another name for the Asian countries and islands, or the East. See also **Far East; Asia**.

Oriental exclusion acts, a series of actions and acts approved by the United States government, restricted and prohibited Asians from entering the United States.

Chinese first came to the United States in large numbers after the discovery of gold in California in 1848. They were initially well received but met hostility as they moved into urban areas. Between 1864 and 1869, Chinese laborers were brought to the United States to help build the Central Pacific Railroad. In 1868, China and the United States signed the Burlingame Treaty to protect this immigration.

During the 1870's, however, the immigration of Chinese coincided with an economic depression, and the Chinese were made the scapegoats. Americans accused them of unfair competition in business, of lowering wages, and of immoral and unsanitary habits. In some instances, they were victims of mob violence. Despite the treaty of 1868, Congress passed the Chinese Exclusion Act of 1882. This law and an extension of it that was passed in 1892 were intended to be only temporary, but Congress made exclusion permanent in 1902.

After the Chinese were barred, Japanese immigrants began coming to the United States in increasing numbers during the late 1800's. Many of them settled on the West Coast and became farmers. Their innovative farming methods, thrift, and low living standards made them a competitive force and aroused the anger of white farmers. California petitioned Congress to extend the Chinese exclusion law to the Japanese. In 1908, a "gentlemen's agreement" between the United States and Japan provided a temporary solution. Japan agreed to stop emigration of its workers to the United States, and the United States agreed to halt discriminatory immigration laws against the Japanese (see **Gentlemen's agreement**). The Immigration Act of 1924 prohibited the entry of all Asian laborers.

During World War II (1939-1945), Congress repealed the laws against the Chinese, permitting a limited number to enter the United States each year and be eligible for citizenship. The Immigration and Nationality Act of 1952 extended the same privileges to other immigrants, including the Japanese. The national quota system was abolished in 1965. Frank J. Coppa

Origami, *AWR uh GAH mee,* is the art of folding paper into decorative objects. The term is the Japanese word for *folded paper*. There are about 100 traditional origami figures. Most depict such natural forms as birds, flowers, and fish. An abstract, ceremonial form of origami, called a *noshi,* is a pleated paper ornament attached to gifts. Most origami is folded from an uncut square of paper. The most common sizes of square are 15 centimeters and 25 centimeters (6 and 10 inches). The preferred paper is thin Japanese paper called *washi*. Foil-backed wrapping paper and heavy art paper are also used.

WORLD BOOK photo by Dan Miller

Origami is the Japanese art of folding paper into decorative objects. Most figures can be made without cutting or pasting.

Origami, like paper, originated in China. But the art flourished in Japan. Since the 1940's, it has reached new levels of complexity and realism. Robert J. Lang

Orinoco River, *OHR uh NOH koh,* is the longest river in Venezuela. It is 1,284 miles (2,066 kilometers) long. The Orinoco has two known sources, both in the Parima highlands in Venezuela, near the border of Brazil. The river flows northwest to Colombia and forms the boundary between Colombia and Venezuela. Then it swings east across Venezuela. About 110 miles (177 kilometers) before it reaches the seacoast, it divides into many channels. For location, see **Venezuela** (terrain map).

Small oceangoing vessels can sail 260 miles (418 kilometers) upstream from the mouth of the Orinoco. Ships can use the river for about 500 miles (800 kilometers) above the Maipures and Atures rapids. Ciudad Bolívar is the center of the Orinoco river trade. Steamships run

between Ciudad Bolívar and the island of Trinidad most of the year. Major branches of the Orinoco are the Apure, Caroní, and Meta rivers. Including its branches, the Orinoco has a navigable length of 4,300 miles (6,920 kilometers). Gregory Knapp

Oriole, *AWR ee ohl.* In America, orioles form a subdivision of the blackbird family. In Europe, the name oriole is given to a family of orange and black birds related to the crows. Most of the American orioles live in or near the tropics. In Jamaica, they are known as *banana birds.*

WORLD BOOK illustration by Trevor Boyer, Linden Artists Ltd.

The orchard oriole is a common American species of oriole. The male, *left,* has darker coloring than the female, *right.*

Three common species of orioles spend the summer in southern Canada and the United States—the *Baltimore oriole, Bullock's oriole,* and the *orchard oriole.*

Orioles have beautifully colored feathers and loud, musical voices. They weave hanging nests and help farmers by eating insects. But in some areas, these birds may eat grapes. Some orioles are also called *troupials.*

Donald F. Bruning

Scientific classification. American orioles belong to the icterid family, Icteridae. The scientific name of the Baltimore oriole is *Icterus galbula.* Bullock's oriole is *I. bullockii,* and the orchard oriole is *I. spurius.*

See also **Baltimore oriole; Bird** (pictures: Birds of forests and woodlands; Birds' eggs).

Orion, *aw RY uhn* or *oh RY uhn,* was a handsome and energetic hunter in Greek mythology. He was a giant who could walk through the sea and on its surface.

Orion had a troubled love life. His wife was sent to Hades after she boasted that she was more beautiful than the goddess Hera (see **Hades**). Because Orion seduced his fiancée, Merope, her father, King Oenopion, blinded him. Helios, the sun god, restored Orion's sight.

According to one myth, Artemis, the goddess of hunting, killed Orion because he tried to rape her. Another myth says that Artemis considered marrying Orion, but her jealous brother Apollo tricked her into hitting Orion with an arrow while he was swimming. In her sorrow at his death, Artemis placed Orion in the sky as a constellation. Another myth tells that Gaea, the earth, sent a scorpion to sting Orion to death. Nancy Felson

Orion, *aw RY uhn* or *oh RY uhn,* the Hunter, is a brilliant constellation that includes two of the brightest stars in the sky. Orion is often pictured with his back turned toward us. In this view, the bright red star, Betelgeuse, marks his left shoulder. A blue-white star called Rigel marks his right foot. Two fainter stars, Bellatrix and Saiph, mark Orion's right shoulder and left foot. Orion is easily identified by a row of three stars forming his belt. A sword, made of faint stars, dangles from the belt.

Two *nebulae* (clouds of gas and dust) are in Orion. The Great Nebula, in the middle of Orion's sword, is visible as a misty spot under a dark sky. The Horsehead Nebula in Orion's belt is difficult to see. David H. Levy

See also **Betelgeuse; Nebula** (picture); **Star** (picture: The constellation Orion).

Orizaba, *AWR uh ZAH buh* or *AW ree SAH vah,* **Pico de,** is the highest mountain in Mexico and the third highest in North America. Only Mount McKinley and Mount Logan are higher. Pico de Orizaba rises 18,410 feet (5,611 meters) above sea level. Its Aztec name, Citlaltépetl, *SEE tlah TAY peht uhl,* means "mountain of the star." The mountain stands about 30 miles (48 kilometers) north of the city of Orizaba, Mexico. It is a volcano, part of Mexico's Neo-Volcanic Chain, that last erupted in the late 1600's. John J. Winberry

See also **Mountain** (diagram: Major mountains).

Orkney Islands are a group of islands that form part of Scotland. They are separated from the north coast of Scotland by the Pentland Firth, a channel about 7 miles (11 kilometers) wide (see **Scotland** [political map]). About 65 islands and some rocky isles make up the Orkney Islands, which have a total land area of about 377 square miles (976 square kilometers). The islands have about 19,000 people. Kirkwall and Stromness are the only towns. They lie on Mainland, the largest island. Nearly all the people are of Scandinavian or Scottish ancestry.

Rich soil and a mild climate help make agriculture the leading industry in the Orkney Islands. The chief products include cattle, cheese, eggs, and barley. Fishing is also an important economic activity. In addition, the islands have a major oil terminal that receives oil piped from wells in the North Sea.

Archaeological evidence indicates that people lived in the Orkney Islands about 5,000 years ago. Vikings from Norway ruled the islands from the A.D. 800's to the 1400's. Most of the islands' place names are of Viking origin. Scotland (now part of the United Kingdom) acquired the Orkney Islands from Norway in 1469, when Scotland's king, James III, married Princess Margaret of Norway and Denmark. The islands served as an important base for the British Navy during World War I (1914-1918) and World War II (1939-1945). H. R. Jones

Orlando, *awr LAN doh,* Florida (pop. 185,951; met. area pop. 1,644,561), is a popular winter resort and tourist center. Orlando's warm climate has helped make it one of the fastest-growing cities in the United States. Walt Disney World Resort opened about 15 miles (24 kilometers) southwest of the city in 1971. This famous entertainment center has contributed greatly to Orlando's rapid growth. Many people, including large numbers of retired citizens, have settled in Orlando because of the mild climate. Orlando's temperature averages 60 °F (16 °C) in January and 83 °F (28 °C) in July.

Orlando, the county seat of Orange County, lies in central Florida (see **Florida** [political map]). Its museums include the Orlando Science Center, which features the

John Young Planetarium; and the Orange County Historical Museum. The University of Central Florida is in Orlando. The city is also the home of the Orlando Magic of the National Basketball Association.

Orlando's chief industry is tourism, and Walt Disney World Resort is its chief employer. Other major employers include Lockheed Martin, an aerospace firm; a hospital; and a chain of supermarkets.

Seminole Indians lived in what is now Orlando before European settlers first arrived in 1837. In 1850, the settlement was named Jernigan for Aaron Jernigan, an Orange County trader. It became known as Orlando in 1857. This name probably honors Orlando Reeves, a soldier who died in a battle with the Indians.

Orlando's first major period of growth followed demands of early citrus fruit growers for better transportation for their crops. A railroad reached the city in 1881, and more planters started citrus groves during the 1890's. In the early 1900's, a real estate boom helped increase the population of Orlando and many other Florida communities. Orlando's population grew from 9,282 in 1920 to 52,367 in 1950.

The development of Walt Disney World Resort led to many construction projects in Orlando. They included apartment buildings, banks, hotels, motels, restaurants, and shopping areas. In 1972, Orlando completed a new Municipal Justice Building. A Civic Theater opened in 1973. In 1982, Walt Disney Productions opened EPCOT Center, a permanent world's fair, at Walt Disney World Resort. Another attraction there is the Disney-MGM Studios Theme Park, which opened in 1989. Animal Kingdom, which opened in 1998, displays hundreds of animals in re-creations of a jungle, savanna, and other habitats. Universal Studios Florida—a motion-picture and television studio and theme park—opened in Orlando in 1990. Orlando has a mayor-council form of government.

Judy L. Grimsley

Orlando, *awr LAN doh,* **Vittorio Emanuele,** *veet TAW ryoh EH mah noo EE leh* (1860-1952), served as prime minister of Italy from 1917 to 1919. He took office just after the Italian Army suffered a terrible defeat at Caporetto (now in Slovenia) in World War I. His efforts to restore civilian morale and army discipline helped keep Italy in the war, on the side of the Allies, until the Allied victory in 1918. After the war, he led the Italian delegation at the Paris Peace Conference in 1919. He temporarily left the conference in protest after the Allies refused to meet Italy's claims to former Austrian territories. His opponents in Parliament later forced him to resign as prime minister.

Orlando supported Benito Mussolini when Mussolini became prime minister of Italy in 1922. But Orlando denounced him in 1925 when Mussolini began openly to create a dictatorship. In 1946, when Italy's monarchy was abolished, Orlando helped establish the Italian republic.

Orlando was born on May 19, 1860, in Palermo. A law professor, he began his political career in the Italian Chamber of Deputies in 1897. He died on Dec. 1, 1952. Susan A. Ashley

Orléans, *AWR lee uhnz* or *AWR lay AHN* (pop. 116,559; met. area pop. 263,292), is an important commercial center in north-central France. The city lies along the Loire River. For location, see **France** (political map).

Orléans is in the Loire Valley, a region that is famous for its many estates and *chateaux* (castles). The city has a number of medieval buildings—including the Gothic Cathedral of St. Croix and the University of Orléans. Orléans grows most of the commercially raised roses in France. Its many other products include automobiles, candies, clothing, computers, electric appliances, farm machinery, liqueurs, and pharmaceuticals.

Roman soldiers established a colony at the site of what is now Orléans in 52 B.C. In 1429, Joan of Arc led the French Army in saving the city from English invasion (see **Joan of Arc, Saint**). Mark Kesselman

Orléans, Battle of. See **Hundred Years' War.**

Ormandy, *AWR muhn dee,* **Eugene** (1899-1985), became one of the world's best-known orchestra conductors as director of the Philadelphia Orchestra. From 1936 to 1938, Ormandy shared leadership of the orchestra with Leopold Stokowski. Ormandy was the orchestra's sole music director from 1938 to 1980. His specialties were Romantic and Neoromantic music in which he emphasized fine string playing and rich orchestral tones. Under his leadership, the orchestra toured many countries and made many recordings.

Eugene Ormandy Blau was born on Nov. 18, 1899, in Budapest, Hungary. He studied the violin with Jenö Hubay, a noted Hungarian violinist. In 1921, Ormandy went to the United States to make a concert tour. Instead, he became a violinist in the orchestra of the Capitol Theater in New York City. Soon he began to conduct, and he became principal conductor of the Minneapolis Symphony Orchestra in 1931. He held this position until moving to Philadelphia. Ormandy became a U.S. citizen in 1927. He died on March 12, 1985. Martin Bernheimer

Ornithischian. See **Dinosaur** (Kinds of dinosaurs).

Ornithology, *AWR nuh THAHL uh jee,* is the scientific study of birds. It includes the description, history, and classification of birds; and their distribution, numbers, activities, ecological importance, and economic value to people. The activities of birds that ornithologists study include mating, nesting, rearing of young, feeding, flight, navigation, migration, and communication. Photography often is used to document the activities of birds, and recordings are made of their songs.

People have valued birds throughout history because of their beauty, their interesting habits, and their importance as a source of food and clothing. Many people belong to bird clubs, and a large number of amateurs participate in ortnithological research. The American Ornithologists' Union, a nonprofit educational organization, was established in 1883. Its headquarters are at the National Museum of Natural History, Smithsonian Institution, in Washington, D.C. Richard E. Bonney, Jr.

Ornithomimus, *AWR nihth uh MY muhs,* was a dinosaur that resembled a modern ostrich. Its name, which means *bird mimic,* refers to the animal's birdlike appearance.

Ornithomimus measured about 10 to 13 feet (3 to 4 meters) in length and stood about 6 to 8 feet (1.8 to 2.4 meters) tall. It had a lightly built body with an elongated neck and tail; short arms; and long, strong hind legs. One of the fastest dinosaurs, *Ornithomimus* may have run as swiftly as an ostrich—30 to 40 miles (48 to 64 kilometers) per hour. It used its speed and keen eyesight to avoid predators. Its tail helped it balance during quick turns.

Ornithomimus had a toothless, beaklike mouth and probably ate eggs, insects, small animals, and fruit. The dinosaur used its long, claw-tipped fingers to uncover food on the ground or to dig for prey. It may also have stolen eggs from the nests of other dinosaurs.

Ornithomimus lived about 76 million to 65 million years ago, during the Late Cretaceous Period. Scientists have found its remains in western North America and central Asia. David B. Weishampel

Ornithopod. See **Dinosaur** (Kinds of dinosaurs).

Ornithopter, *AWR nuh THAHP tuhr,* is a machine designed to fly by flapping its wings like a bird. People have dreamed of such a vehicle since ancient times. Some small-scale models have flown. But all attempts to build ornithopters that carry people have failed because materials that are light enough and strong enough have not been developed.

Ornithopters are classified in two ways. The first type uses various forms of wings fastened to a person's body. The second type uses a cockpit to house the pilot. The wings are attached and operated from the cockpit. The English philosopher Roger Bacon suggested the idea of the ornithopter about 1250. Roger E. Bilstein

Oroville Dam, *OHR uh vihl,* is the highest dam in the United States. It rises 754 feet (230 meters) and extends 6,800 feet (2,073 meters) across the Feather River, near Oroville, California. The Oroville Dam is the chief dam of the State Water Project, which supplies irrigation water to central and southern California.

The dam is an earth-fill dam (see **Dam** [Embankment dams]). About 80 million cubic yards (61 million cubic meters) of earth materials were used in its construction. It was completed in 1968. The materials came from waste piles at nearby gold-mining operations.

The Oroville Dam forms a reservoir called Lake Oroville, which contains about 3 $\frac{1}{2}$ million acre-feet (4.3 billion cubic meters) of water. Water from Lake Oroville is used to irrigate farmland as far as 650 miles (1,050 kilometers) away in southern California. A hydroelectric power plant connected to the dam also uses the water. The dam also helps control floods. Allen Soast

Orozco, *oh ROHS koh,* **José Clemente,** *hoh SAY klay MAYN tay* (1883-1949), a Mexican painter, became known for murals that use themes from Mexico's history. His style emphasizes human figures who are portrayed with strong lines, dramatic angles, and brownish colors.

Orozco was born on Nov. 23, 1883, in Zapotlán. He spent his early career drawing political and satirical cartoons. In the early 1920's, Orozco and other Mexican artists began painting frescoes on walls in public buildings (see **Fresco**). Unlike the work of fellow muralists Diego Rivera and David Siqueiros, Orozco's frescoes seldom contain political messages. Instead, his paintings express his reaction to the struggles of common people everywhere.

Detail of a fresco (1934); courtesy of the Trustees of Dartmouth College

An Orozco mural shows the god Quetzalcóatl rising above Aztec temples to arouse the Indians to improve their culture. The Aztec believed the god brought knowledge and civilization.

In the 1930's, Orozco turned to a more abstract style. Examples of this style include the murals called *Epic of New World Culture* (1932-1934) in the Dartmouth College library in Hanover, New Hampshire, and murals in public buildings in Guadalajara and Mexico City. He died on Sept. 7, 1949. Judith Berg Sobré

Orphanage. See **Children's home.**

Orpheus, *AWR fee uhs* or *OHR fyoos,* was a musician in Greek and Roman mythology. The music of his voice and lyre was so beautiful that animals, trees, and stones followed him, and rivers stopped flowing to listen. His mother was the muse Calliope, and his father was either the mortal Oeagrus or the god Apollo.

Orpheus joined the Argonauts in their quest to capture the Golden Fleece. Later, he married Eurydice. After Eurydice died, he went to the underworld to bring her back. His music charmed Hades and Persephone, the rulers of the underworld, and they granted Eurydice permission to leave. But they warned Orpheus not to look back at her on the way up to the earth. He glanced back too soon and she disappeared. Orpheus angered some women of Thrace because he took no interest in them or in their worship of the god Dionysus, and they tore him to pieces. Justin M. Glenn

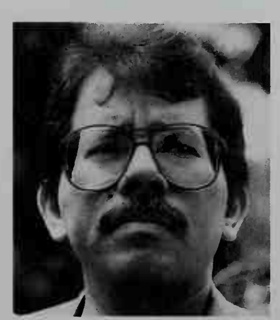
Orr, Bobby (1948-), was one of the greatest defensemen in professional hockey history. He revolutionized the position with his graceful skating and extraordinary ability to carry the puck up the ice without weakening his team's defense. Orr's 139 points in the 1970-1971 season remains a record for National Hockey League (NHL) defensemen. Orr is the only defenseman to have

led the NHL in scoring, doing this in the 1969-1970 and 1974-1975 seasons. He won the Hart Memorial Trophy as Most Valuable Player in the NHL three seasons, from 1969-1970 through 1971-1972. He captured the James Norris Memorial Trophy as the league's best defenseman a record eight consecutive seasons, from 1967-1968 through 1974-1975.

United Press Int.
Bobby Orr

Robert Gordon Orr was born on March 20, 1948, in Parry Sound, Ontario. He played for the Boston Bruins from 1966 to 1976. Orr signed with the Chicago Black Hawks in 1976. He retired in 1978 because of knee problems. Larry Wigge



Orrisroot, *AWR ihs ROOT,* is the dried, sweet-smelling *rhizome* (underground stem) of certain irises. Orrisroot yields a waxy material containing a fragrant oil that is used to give perfumes a scent like that of violets. The oil is obtained by dissolving the waxy material in a fat or other organic substance. That substance is then removed leaving the oil.

Because of its high price, the oil has largely been replaced by synthetic substitutes. But small amounts are still used in some expensive perfumes. Orrisroot comes from irises cultivated in Italy, France, India, and Morocco. James E. Simon

See also **Iris**.

Ortega, *awr TAY gah,* **Daniel** (1945-), was head of Nicaragua's government from 1979 until 1990. In 1979, he was named the leader of a revolutionary government when his party, the Sandinista National Liberation Front, overthrew the government of Anastasio Somoza Debayle. Ortega was elected president of Nicaragua in 1984. His term as president ended in 1990, when he was defeated in a presidential election by Violeta Barrios de Chamorro, the leader of a coalition that opposed Sandinista rule. Ortega ran for president of Nicaragua again in 1996 and 2001, but he was defeated both times by candidates from the Liberal Constitutionalist Party.

Under Ortega, Nicaragua's government improved health care in rural areas, built many new schools, and reduced illiteracy. It also took control of many businesses, increased press censorship, and restricted the civil rights of its political opponents. Critics of Ortega, including the United States government, charged that he had set up a Communist dictatorship. In 1981, Nicaraguans who opposed Ortega's government—called *contras*—began a guerrilla war against it. In 1988, Ortega helped negotiate a cease-fire between his government and the contras.

© Jack McKigney, Picture Group
Daniel Ortega

Ortega's leadership of Nicaragua was greatly influenced by the country's relationship with the United States. The United States had been Nicaragua's chief trading partner until the Sandinista party came to power. The United States opposed Ortega's leadership. It sharply reduced trade with Nicaragua and provided funds to the contras. Ortega struggled to improve an economy crippled by the U.S. trade cuts, by the war against the contras, and by high government spending for health and education programs.

Ortega was born on Nov. 11, 1945, in the town of La Libertad. His full name is Daniel José Ortega Saavedra. During the 1960's, Ortega became a guerrilla leader of the Sandinista opposition to the Somoza government. He was imprisoned by the government from 1967 to 1974. After receiving military training in Cuba, he helped lead the overthrow of the Somoza government.

Neale J. Pearson

Ortega y Gasset, *awr TAY guh ee gah SEHT,* **José** (1883-1955), was a Spanish philosopher and essayist. He wrote *Meditations on Quixote* (1914), which anticipated themes that existentialist philosophers made popular more than 10 years later. Ortega emphasized the idea that we are "condemned to be free," and therefore all individuals must determine their own place in history. See **Existentialism**.

Ortega cherished aristocratic values. He believed that without spiritual leadership from the top, society would be drawn down to the level of its lowest members. For Ortega, this problem was especially serious because of the decline of self-confidence that he saw in Europe, and the rise of merely technical modes of thought and organization in the 1900's. He explored these ideas in his best-known book, *The Revolt of the Masses* (1930). In *The Dehumanization of Art* (1925), Ortega discussed the tendency of modern art to rid itself of human content.

Ortega was born on May 9, 1883, in Madrid. He was strongly influenced by the ideas of the German philosopher Immanuel Kant while he was studying in Germany. Ortega was professor of philosophy at Madrid University from 1910 to 1936. Because of the Spanish Civil War, he lived in exile from 1936 to 1945, when he returned to Spain. He died on Oct. 18, 1955. Karl Ameriks

Orthodontics, *AWR thuh DAHN tihks,* is the branch of dentistry that prevents and corrects irregular positions of the teeth. In addition to causing poor personal appearance, irregularly positioned teeth are difficult to clean. Thus, they are more likely to decay and promote gum diseases (see **Teeth** [Periodontal diseases]). Irregularly positioned teeth also can cause chewing and speech problems and can damage the jaw.

Irregularities in the position of teeth are called *malocclusions.* Malocclusions usually arise during childhood as the teeth grow. They most commonly occur when the teeth are too large for the available jaw space. Under such conditions, the teeth become crowded and turned out of position. In some cases, one of the jawbones is larger than the other, creating either an overbite or an underbite.

Malocclusions can sometimes be prevented by the early removal of certain *deciduous teeth* (baby teeth). This process, called *serial extraction* or *guidance eruption,* relieves crowding that occurs as new teeth break through the gums. If the teeth are already out of posi-

tion, orthodontists cement metal or plastic braces to the front of each tooth and connect the braces with wires. By gradually tightening the wires, they move the teeth into proper position. In some cases, a tooth is extracted so that other teeth can be moved into its place. Orthodontic treatment is sometimes combined with surgery on the jawbones to correct malocclusions.

Orthodontic treatment is typically begun when patients are 10 to 16 years old and lasts about two years. Many adults also undergo orthodontic treatment, but treatment time is generally longer. John P. Wortel

See also Dentistry (Orthodontics [picture]); Teeth (Malocclusion).

Orthodox, Eastern. See Eastern Orthodox Churches.

Orthopedics, *AWR thuh PEE dihks,* is a branch of medicine that deals with disorders of the bones and muscles and their associated tissues. The word is also spelled *orthopaedics.* Doctors who practice orthopedics are called *orthopedists* or *orthopedic surgeons.* They treat a broad range of medical problems, including fractures, injuries to tendons and ligaments, and deformities of the limbs and spine.

Orthopedists provide care for patients who range from the newborn to the elderly. Some orthopedic disorders are present at birth. Others occur during childhood due to problems of growth or in later life as a result of aging. Still others result from injury or illness. People injured in automobile accidents and athletic or recreational activities account for a large number of the patients treated by orthopedists.

In treating orthopedic disorders, orthopedists prescribe drugs, surgery, or physical therapy. For example, an orthopedist may perform surgery to correct a fracture or deformity. After the surgery, the orthopedist may apply a cast or brace and prescribe physical therapy to aid healing. An orthopedist also may perform surgery to replace an injured or arthritic joint with an artificial joint made of plastic, metal, or other materials. Joints most commonly replaced include the hip, the knee, and joints in the hands and feet. William J. Kane

Orwell, George, was the pen name of Eric Arthur Blair (1903-1950), a British novelist and social critic. Orwell became famous with his novel *1984,* published in 1949. The book is a frightening portrait of a totalitarian society that punishes love, destroys privacy, and distorts truth. The novel includes the well-known statement "Big Brother Is Watching You." The grim tone of *1984* distinguishes it from Orwell's *Animal Farm* (1945), a fable satirizing Communism. In *Animal Farm,* Orwell wrote the familiar saying "All animals are equal, but some animals are more equal than others."

AP Wide World
George Orwell

Orwell was a unique combination of middle-class intellectual and working-class reformer. A strong autobiographical element runs through most of Orwell's writing, giving both his novels and essays a sense of immediacy and conviction. Orwell's experiences living in poverty color *Down and Out in Paris and London* (1933), *A Clergyman's Daughter* (1935), and *The Road to Wigan Pier* (1937). The novels attack social injustice and range from the miseries and hypocrisies of the poor from middle-class backgrounds to the near-starvation of the slum-dweller. *Homage to Catalonia* (1938) is a nonfiction work based on Orwell's brief career as a soldier. In it, he describes his disillusionment with the Loyalists during the Spanish Civil War.

Orwell was born on June 25, 1903, in Bengal, India, the son of a British civil servant. He attended Eton from 1917 to 1921 and served with the Indian Imperial Police in Burma (now Myanmar) from 1922 to 1927. He lived in poverty in England and Europe until the mid-1930's.

Osage Indians, *OH sayj,* once gathered food and hunted buffalo throughout a vast region of what are now Arkansas, Kansas, Missouri, and Oklahoma. The tribe also had permanent camps along the Osage River, which was named for them. The Osage lost most of their land to the United States government as a result of treaties made from 1808 to 1870. In 1872, the tribe moved to a reservation in Oklahoma and took up farming.

Oil was discovered on the Osage reservation in the late 1800's, and it produced income that made the tribe extremely wealthy. Many Osage then intermarried with whites and adopted white lifestyles. Today, however, the Osage are trying to preserve some aspects of their culture, including their language and religious ceremonies. Some Osage still live in Oklahoma, but many others live elsewhere. Helen Marie Redbird-Smith

Osage orange, *OH sayj,* is a small- to medium-sized tree planted across the United States for hedges, ornamental purposes, and shade. It originally was found in Texas, Oklahoma, and Arkansas. The name refers to the Osage Indians of that region, and to the tree's greenish-yellow fruit, which looks like an orange but is inedible. The Osage orange is sometimes called *bodark, bois d'arc, bowwood,* or *hedge apple.*

WORLD BOOK illustration by Chris Skilton

The Osage orange has greenish-yellow fruit that resembles an orange. The tree has a short trunk and crooked branches and long, pointed leaves. Its yellow wood is hard and durable.

The tree has a short trunk and crooked branches. Its long, pointed leaves are a shiny, dark green. It has thorny twigs and a milky, bitter sap. Pioneers planted Osage orange trees as a "living fence" around their farms before barbed wire came into use.

The yellow wood of the Osage orange is hard, strong, and durable. The Indians preferred it for their bows and war clubs. It makes good fence posts and was used for wagon wheels. A yellow dye can be made by boiling chips of the wood in water. Norman L. Christensen, Jr.

Scientific classification. The Osage orange tree belongs to the mulberry family, Moraceae. It is *Maclura pomifera.*

Osaka, *oh SAH kuh* (pop. 2,598,589), is the third largest city in Japan. Only Tokyo and Yokohama have more people. Osaka, an important industrial and commercial center, lies on Osaka Bay on the southern coast of Honshu Island (see **Japan** [political map]).

Osaka covers about 80 square miles (206 square kilometers). It is sometimes called the "Venice of Japan" because of its many canals and rivers. Since the 1960's, some of these waterways have been filled and highways built over them. Downtown Osaka lies on the delta of the Yodo River. Office buildings, stores, hotels, restaurants, and entertainment centers fill this section of the city. Many shopping centers have been built underground because of a shortage of land.

Osaka has many museums, theaters, and religious shrines. Osaka Castle, built in 1584, houses a museum with historical exhibits. Bunraku Theater presents puppet shows, and Kabuki Theater offers stage performances. Osaka has 13 universities, including government-supported Osaka University. In 1970, Osaka was the site of Expo '70, the first world's fair to be held in Asia.

In the past, most Osakans lived in small wooden houses. Today, many Osaka residents live in large apartment buildings. The city's population increased by more than a million during the 1950's, and this rapid growth led to shortages of land and housing. Many Osakans have moved to the suburbs to escape the city's crowded conditions, high prices, and pollution.

World Photo Service from Madeline Grimaldi

Osaka, Japan's third largest city, is an important commercial and cultural center. Numerous canals and rivers run through the city, which lies on the southern coast of Honshu Island.

Osaka is famous for its good food, especially seafood. Local specialties include eel; shrimp; turtle; and *kaminabe,* a fish stew cooked in a paper pot.

Osaka produces approximately 25 percent of all the products manufactured in Japan, including 40 percent of Japan's exports. Osaka exports clothing, electrical appliances, and fabrics. The city is also a financial and trade center.

Osaka has serious traffic problems in spite of efforts to improve public transportation. Buses, a subway system, and commuter trains serve the city. High-speed trains travel between Osaka and Tokyo, a distance of about 250 miles (400 kilometers). Osaka has two airports, Kansai International Airport and Osaka Airport. Kansai International is one of the busiest airports in Asia.

Osaka was settled in ancient times. It later became Japan's major port and commercial center. Toyotomi Hideyoshi, the ruler of Japan from 1585 to 1598, encouraged merchants to move to Osaka. The government opened Osaka's port to foreign trade in 1868.

Allied bombing raids destroyed much of Osaka during World War II (1939-1945). The people rebuilt their city following the war. Osaka's population growth created a need for more housing, sewers, highways, and subways. Many of these improvements were completed during the city's preparations for Expo '70.

Kenneth B. Pyle

Osborn, Henry Fairfield (1857-1935), was an American *paleontologist* (expert on prehistoric life). He was an authority on fossil vertebrate animals and evolution. His best-known work consisted of his studies of ancient reptiles and mammals. Osborn wrote about rhinoceroses; elephants and their relatives; and *titanotheres,* large mammals that once roamed the American West. Osborn's book *From the Greeks to Darwin* (1894) discussed evolution.

Osborn served as president of the American Museum of Natural History in New York City from 1908 to 1933. Under his administration, it became one of the world's largest museums. Osborn was born on Aug. 8, 1857, in Fairfield, Connecticut. Carolyn Merchant

Osborne, John (1929-1994), a British dramatist, became famous with his first important play, *Look Back in Anger* (1956). The drama deals with Jimmy Porter, an educated but poor young man. Porter lashes out at everyone around him in anger and frustration because the world no longer offers any ideals or causes he can believe in. The play was a vivid contrast to the sort of polite upper-middle-class stories and characters presented in most British plays of the time. Osborne continued the story of Jimmy Porter's life in *Dejavu* (1992).

Osborne's other early plays also criticized society. *The Entertainer* (1957) uses a run-down old comedian to symbolize the decline of the British Empire. *Luther* (1961) presents a modern interpretation of Reformation religious leader Martin Luther as a troubled rebel. *Inadmissible Evidence* (1964) portrays the breakdown of a successful lawyer as he realizes how empty his life is.

As Osborne grew older, his plays became more conservative. He defended the way of life he had once criticized, and he attacked younger social critics. He also wrote an autobiography, *A Better Class of Person* (1981). John James Osborne was born on Dec. 12, 1929, in London. He died on Dec. 24, 1994. Gerald M. Berkowitz

Osborne, Thomas Mott (1859-1926), was an American prison reformer. In 1913, as chairman of the New York State Commission for Prison Reform, he spent a week in prison, secretly, so he could understand and help prisoners. He served as warden of Sing Sing (New York) Prison from 1914 to 1916 and of Portsmouth (New Hampshire) Naval Prison from 1917 to 1920. Osborne organized the Mutual Welfare League to help prisoners rebuild their lives. He wrote *Within Prison Walls* (1914) and *Society and Prisons* (1916). Osborne was born on Sept. 23, 1859, in Auburn, New York, and died there on Oct. 20, 1926. Louis Filler

Oscan, *AHS kuhn,* was a language used by one of the earliest known peoples of Italy. It was part of the Indo-European family and was distantly related to Latin.

Oscar. See Motion picture (Festivals and awards).

Osceola, *AHS ee OH luh* (1804?-1838), led the Seminole Indians in Florida during the Second Seminole War (1835-1842). He fought attempts by the United States Army to move the tribe west of the Mississippi River to the Indian Territory.

Osceola was born in a Creek Indian village near the Tallapoosa River in what is now eastern Alabama. The name *Osceola,* or *Asi-Yaholo,* comes from *asi,* a drink containing caffeine; and *Yaholo,* a cry shouted by the men who served asi during tribal ceremonies. After the Creek War (1813-1814), Osceola and many Creeks retreated to Florida and joined the Seminole.

During the 1820's, Osceola became known as a successful hunter and war leader. His warriors defeated United States troops in several battles early in the Second Seminole War. In 1837, Osceola met with U.S. troops under a flag of truce to discuss peace. But General Thomas Jesup ordered the troops to capture and imprison him. Osceola died soon afterward—on Jan. 30, 1838—in the Fort Moultrie prison near Charleston, South Carolina.

Detail of a painting (1838) by George Catlin; National Portrait Gallery, Smithsonian Institution

Osceola

Many Americans were outraged by Jesup's trickery, and the Army's reputation fell sharply. Osceola won widespread respect. Several towns and counties were named for him. Michael D. Green

Oscillograph. See Oscilloscope.

Oscilloscope, *uh SIHL uh skohp,* is an electronic instrument that displays changing electrical signals. The signals appear as wavy lines or in other patterns on a fluorescent screen.

Oscilloscopes are used in such fields as industry, medicine, and scientific research. Electronics engineers use the instruments to test computers, radios, and other electronic equipment. Physicians use them to study electrical impulses from the brain or heart. Light, mechanical motion, and sound can be studied with oscilloscopes. Devices called *transducers* change these forms of energy into electrical signals.

The screen of an oscilloscope is the front of a *cathode-ray tube,* a special type of vacuum tube. Inside the tube, a device called an *electron gun* projects a beam of electrons onto the fluorescent screen. Any sideways or

© Peter Aprahamian, SPL/SS from Photo Researchers

An oscilloscope shows electrical or sound waves or other vibrations as patterns on a fluorescent screen.

up-and-down movement of this beam leaves a glowing line on the screen. A circuit called the *time base* causes the beam to move repeatedly from left to right. At the same time, the signal to be studied is fed into the oscilloscope and causes the beam to move up and down. This movement corresponds to *oscillations* (vibrations) in the signal. The beam moves up and down while moving from left to right. As a result, the beam traces a pattern on the screen that represents the oscillating signal.

A *digital oscilloscope* can "remember" the signal and so can recall and repeatedly display a brief event, such as the seismic wave of an earthquake. The oscilloscope measures the signal and stores it in a computerlike memory as a sequence of 1's and 0's. The measurements usually can be recalled at a faster or slower rate than they were recorded. For example, a seismic wave that lasted half a minute can be played back in as little as a fraction of a second.

An oscillograph is a type of oscilloscope that can record electrical signals. Certain types of oscillographs change electrical signals into mechanical movements that are recorded on paper or photographic film. For example, some oscillographs use a lightweight pen called a *stylus* to draw a wavy line on a moving paper chart. Richard W. Henry

OSHA. See Occupational Safety and Health Administration.

Oshawa, *AHSH uh wuh* (pop. 139,051; met. area pop. 296,298), is an important Canadian industrial city in Ontario. It is sometimes called *Canada's Motor City.* The city is the home of General Motors of Canada, the nation's largest manufacturer of motor vehicles. Oshawa lies on Lake Ontario in southeastern Ontario. For location, see **Ontario** (political map).

The Oshawa area was first settled in 1794, when Benjamin Wilson, a Vermont farmer, and his family moved there. In 1842, the community was named *Oshawa,* an American Indian word meaning *crossing between the waters.* The community was given this name because it lay between Lake Ontario and Lake Scugog.

In 1907, R. S. McLaughlin established the McLaughlin Motor Car Company in Oshawa. This firm produced McLaughlin-Buick automobiles. The Chevrolet Motor Car Company of Canada was established in Oshawa in 1915. The two firms united in 1918 to form General Motors of Canada. Oshawa received a city charter in 1924.

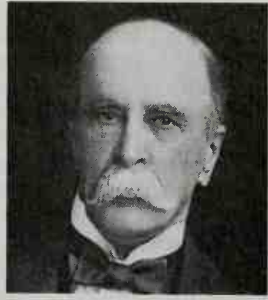
General Motors of Canada is Oshawa's chief employer. Other major employers include automobile parts manufacturers, the provincial headquarters of the Ontario Ministry of Revenue, the city's hospital, and regional school boards. Oshawa has a mayor-council form of government. James Palmateer

Osier, *OH zhuhr,* is the name of certain shrubs and small trees in the willow family. They grow best along streams. These willows have tough, slender stems that can be used for making baskets and furniture. The *common osier,* also called *basket willow,* and the *purple osier* are willows that have been brought to the United States from other parts of the world. They are cultivated for their flexible stems. In the Northeast, they have escaped from cultivation and grow wild. One dogwood is called *red-osier dogwood* because its bark resembles that of some willows. See also **Willow.**

Scientific classification. Osiers belong to the willow family, Salicaceae. The common osier is *Salix viminalis.* The purple osier is *S. purpurea.* The red-osier dogwood is in the dogwood family, Cornaceae. It is *Cornus stolonifera.*

Richard C. Schlesinger

Osiris, *oh SY rihs,* was an Egyptian fertility god who became the chief god of the underworld. He is generally shown as a bearded human mummy with green or black flesh. He holds a shepherd's crook and a whip and wears a conical white crown with ostrich feathers.



As son of the earth god Geb, Osiris was regarded as a source of the earth's fertility. Egyptians sometimes compared him to the Nile River. As a popular Egyptian deity, Osiris was often identified with other deities. At Busiris in the delta region, he absorbed the characteristics of an earlier god-king. At the burial ground at Abydos, he replaced a god of the dead.

In Egyptian royal theology, the king was a living Horus, who was the son of Osiris. After the king died, he became Osiris. After Egyptian funeral practices became more democratic, every Egyptian expected to become an Osiris after death. Osiris was the central figure in Egypt's most popular myth. For an account of this myth, see **Mythology** (Egyptian mythology). Orval Wintermute

Osler, *OHS luhr,* **Sir William** (1849-1919), was a Canadian physician and one of the greatest medical educators. His brilliant teaching and informal and genial personality greatly influenced many of his students. Through his students, Osler influenced medicine in English-speaking countries throughout the world.

One of Osler's most notable contributions to medicine was the organization of a clinic at the Johns Hopkins Hospital in Baltimore, Md. It became the model for modern medical education in the United States. Osler strongly favored using "the patient for a text," and he perfected the method of teaching that encourages students to become actively involved in patient care and learn the art of medicine at the bedside.

Culver

Sir William Osler

Osler discovered the presence in the bloodstream of what later were called *disks,* or *blood platelets* (see **Blood** [Platelets]). Among his many scientific papers are important studies of the heart and research on typhoid fever, pneumonia, malaria, infant mortality, and other medical and public health problems. He also helped found the Association of American Physicians in 1886 and the National Tuberculosis Association (now the American Lung Association) in 1904.

His writings. Osler published *Principles and Practice of Medicine* in 1892. For many years, it was a standard textbook in the United States. In 1897, a member of John D. Rockefeller's philanthropic staff read the book and was inspired by the potential of medical research, especially in microbiology. This incident led to the founding of the Rockefeller Institute for Medical Research in 1901. Osler's humanistic essays were collected in *Aequanimitas* (1904) and *An Alabama Student* (1908).

SCALA/Art Resource

Osiris was one of the principal ancient Egyptian gods. He ruled the underworld and is often portrayed as a mummy seated on a throne wearing the crown of Upper Egypt.

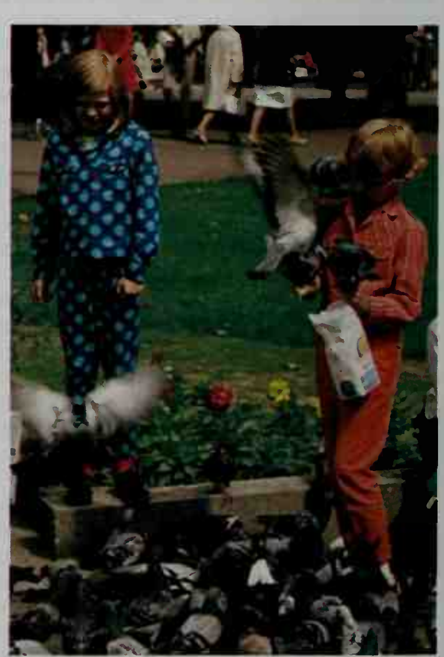
His life. Osler was born on July 12, 1849, in Bondhead, Ont., Canada. He graduated from McGill University in 1872. He served at McGill from 1875 to 1884 as a lecturer in physiology and as professor of medicine. In 1884, he became clinical professor of medicine at the University of Pennsylvania. He was appointed professor of medicine at the new Johns Hopkins University four years later. At the same time, he was made physician-in-chief to the new hospital there. Osler went to Oxford University in 1905 as regius professor of medicine, one of the most prestigious medical positions in Great Britain. He became a baronet in 1911. He helped organize the British medical profession during World War I to meet the war emergency. Dale C. Smith

Oslo (pop. 457,818) is the capital and largest city of Norway. It is also the nation's chief economic, industrial, and cultural center, and one of its leading seaports. Oslo lies on the southeast coast at the head of the great Oslo Fiord. The city is about 80 miles (130 kilometers) north of the Skagerrak, an arm of the North Sea (see **Norway** [map]). From 1624 until 1925, Oslo was called Christiania in honor of King Christian IV, who planned the rebuilding of the city after a fire destroyed it.

The Oslo metropolitan area covers about 175 square miles (454 square kilometers). But over two-thirds of the metropolitan area consists of forests and lakes. These features make the city a favorite recreation center.

The Royal Palace and the Parliament Building stand along Karl Johans Gate, the main street in the central section of Oslo. City Hall, the medieval Akershus Castle, and the city's commercial district are south of Karl Johans Gate. Most of Oslo's people live in apartment buildings. The majority of Oslo's single-family homes are located in outlying areas of the city.

Oslo has Norway's oldest and largest university, an Evangelical Lutheran cathedral, and many museums. The Viking Ships Museum displays ships used by the Vikings about a thousand years ago. The Fram and Kon-Tiki museums house the *Fram,* a famous polar exploration ship; and the *Kon-Tiki,* the raft of anthropologist and adventurer Thor Heyerdahl (see **Heyerdahl, Thor**). Other museums include the Norwegian Folk Museum, Norwegian Maritime Museum, Historical Museum, and Edvard Munch Museum. About 150 works by Gustav Vigeland, one of Norway's greatest sculptors, are in Oslo's Frogner Park.



Manufacturing employs about 25 per cent of Oslo's workers. Major industries include shipbuilding and the production of chemicals, machinery, metals, paper, textiles, and wood products. Banking, communications, electronics, food processing, shipping, and tourism also play important roles in the city's economy. Oslo is the hub of the Norwegian national railroad system. An international airport lies just outside the city.

Oslo was founded by King Harold Hårdråde about 1050. In 1299, Akershus Castle was built on a rocky peninsula overlooking the fiord. Fire destroyed Oslo in 1624, but the people rebuilt the city northeast of the castle. Norway was united with Denmark from 1380 to 1814, and with Sweden from 1814 to 1905. In 1905, it became independent, with Oslo as the capital. By the mid-1800's, the city had grown into a major administrative, economic, and military center. The development of shipping and industry, plus the forest and agricultural resources of southeastern Norway, soon helped give Oslo the dominant role in the nation's economy that it still has today. M. Donald Hancock

Dale Brown, DPI

Adeline Haaga, Tom Stack & Assoc.

Oslo is the capital and largest city of Norway. It also ranks as the country's leading seaport. Passenger ships, cargo vessels, and fishing boats dock at Oslo's busy harbor, *above left.* Many parks and gardens, such as the one shown above at the right, add to the scenic beauty of the city.

Osman I, *AHZ muhn, AHS muhn,* or *ahs MAHN* (1258?-1326?), was the founder of the Ottoman Empire, which was named after him. Osman became known as a skillful military leader and a just ruler.

Osman, who is sometimes called *Othman* or *Uthman,* was probably born near Bursa, in northwestern Anatolia (now Turkey). His father was the leader of a group of nomadic Turks who were originally from Central Asia. According to some historical traditions, this group settled in Anatolia in the 1200's. At first, they served as soldiers for the Seljuks, who ruled much of the region. After he succeeded his father as leader in the 1280's, Osman established a small independent state in the Sakarya Valley in northwestern Anatolia.

Osman gradually expanded Ottoman territory by conquering small neighboring states or forming alliances with them. In 1301, he defeated an army of the nearby Byzantine Empire in the Battle of Baphaeon. About 1324, Osman turned over leadership of the Ottomans to his son Orhan. Virginia H. Aksan

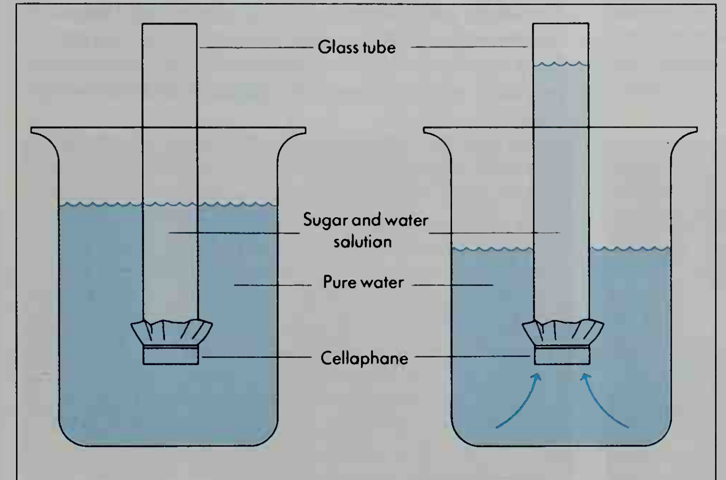
Osmium, *AHZ mee uhm,* is a hard metallic element. It is one of the densest elements, with a density of 22.57 grams per cubic centimeter. Its atomic number is 76, and its atomic weight is 190.23. Its chemical symbol is Os. Smithson Tennant, a British chemist, discovered osmium in 1804. Osmium is rare and expensive and is found in the same ores as platinum. Osmium occurs in Alaska, Borneo, South Africa, and in meteorites.

Refined osmium is a fine, black powder or a hard, blue-gray mass. Osmium has a boiling point of 5012±100 °C and a melting point of 3033±30 °C. When heated in air, osmium forms *osmium tetroxide* (OsO_4), which vaporizes at about 100 °C. This compound can damage the eyes, skin, and lungs. It is used in certain scientific processes. Osmium alloys, which resist corrosion, are used to tip penpoints and are used in mechanical parts. Emily Jane Rose

Osmosis, *ahz MOH sihs,* is the movement of liquid from one solution through a special membrane into a more concentrated solution. The process is essential for the survival of living things. For example, plants absorb most of their water by osmosis. In animals, osmosis helps regulate the flow of water and nutrients between body fluids and cells. Industries reverse osmosis for such purposes as water purification and food preservation.

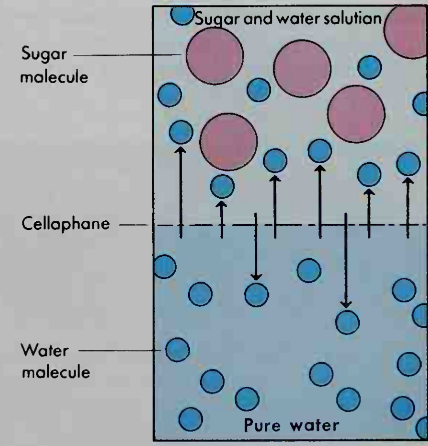
A liquid solution consists of a dissolved substance called a *solute,* and a liquid called a *solvent.* During osmosis, some of the solvent from one solution moves through microscopic holes in a membrane into another solution. The membrane is *semipermeable*—that is, it allows solvent molecules to pass through its holes, but it blocks solute molecules. The solute molecules are larger than the holes in the membrane.

In osmosis, more solvent moves into the solution with the greater concentration of solute molecules. This occurs mostly because, in the weaker solution, there are fewer solute molecules blocking the movement of the solvent.



Solvent from the weaker solution continues to dilute the more concentrated solution until the concentrations are equal. At this point, the amount of solvent entering each solution equals the amount leaving each solution.

However, the flow of solvent will stop before the concentrations become equal if a certain pressure is exerted on the more concentrated solution. This pressure is called the *osmotic pressure.*



Experiment. Osmosis can be demonstrated by performing the following experiment. First, fasten a piece of cellophane over the bottom of a glass tube. Next, pour a solution of sugar and water into the tube. Then place the tube into a container of pure water so the levels of the water and the sugar solution are equal. After several hours, the liquid in the tube rises because of osmosis.

In this experiment, the cellophane is the semipermeable membrane. It allows water molecules to pass through but blocks sugar molecules. The sugar molecules are too large. In the tube, the sugar molecules interfere with the water molecules and prevent some wa-

An osmosis experiment

The process of osmosis can be demonstrated in the experiment shown above. Water enters the glass tube through the cellophane, which serves as a semipermeable membrane. As the water mixes with the sugar solution, the solution rises.

WORLD BOOK diagrams

Molecules of water pass through the cellophane, as shown in the above diagram, but the larger sugar molecules do not. The level of the sugar solution rises because more water molecules move into the solution than out of it.

ter from moving through the membrane. As a result, more water moves into the tube than out of it.

As water moves into the tube, the sugar solution rises, thereby increasing the pressure in the tube. The solution continues to rise until the pressure that it exerts equals that of the pure water.

Reverse osmosis. Chemists use a process called *reverse osmosis* to purify water and perform other functions. In normal osmosis, water flows from fresh water into seawater when they are separated by an appropriate semipermeable membrane. But, by applying pressure to the seawater, chemists can reverse the movement of the water and produce fresh water from seawater. Some shipwreck victims have used survival kits that convert seawater into drinking water by osmosis (see **Water** [diagram: Reverse osmosis]). John B. Butt

Osprey, *AHS pree* or *AH spray,* also called *fish hawk,* is a fish-eating bird. Ospreys feed by making spectacular plunges into water from heights of 50 to 100 feet (15 to 30 meters). They hit the water feet first with a great splash and seize a fish with their long, slender claws. These birds live throughout the world along rivers, lakes, seacoasts, and bays. Ospreys in northern regions migrate to warm areas for the winter.

The osprey is about 2 feet (60 centimeters) long, with a wingspread of nearly 6 feet (1.8 meters). It is dark brown above and has some white on its head. It is white below with a few streaks of dark brown.

WORLD BOOK illustration by Trevor Boyer, Linden Artists Ltd.

The osprey is a brown-and-white bird of prey. It lives near bodies of water and feeds on fish swimming near the surface.

Ospreys nest in trees, jagged rocks, or low bushes, or on the ground. Ospreys build the largest nests of any North American birds. Some measure up to 6 feet (1.8 meters) high. Nest-building materials include seaweed, sticks, bones, or driftwood. In North America, during April or May, ospreys usually lay three eggs. Incubation of the eggs lasts about 37 days.

Insecticides, such as DDT, and human disturbance of the bird's habitat reduced the number of ospreys in several locations. However, conservation measures on the United States mainland helped to increase the osprey population. Thomas G. Balgooyen

Scientific classification. The osprey belongs to the family Accipitridae. Its scientific name is *Pandion haliaetus.*

Ossining Correctional Facility. See Sing Sing.

Ostend, *ah STEHND* (pop. 69,067), is a Belgian city on the North Sea, about 77 miles (124 kilometers) northwest of Brussels (see **Belgium** [political map]). Ostend lies in the Dutch-speaking region of Belgium. Its name in Dutch is *Oostende.* It is an important Belgian port. Ostend conducts an export-import business with many countries. The city serves as the harbor for cross-channel boats from Dover, England. Ostend fishing crews catch cod and herring. Oysters are cultivated offshore. Ostend is a fashionable summer resort. Visitors enjoy its sea walk and listen to concerts in a building called the Kursaal.

Dutch, Spanish, and French troops have fought many battles for Ostend because of its value as a port. In 1865, its fortifications were destroyed by the Belgian government, and Ostend became important for shipping. Ostend was damaged in World War I (1914-1918) and again in World War II (1939-1945). Aristide R. Zolberg

Ostend Manifesto, *ah STEHND,* was a controversial document drafted in 1854 as part of a plan by the United States to acquire the colony of Cuba from Spain. It stated that the United States might be justified in seizing Cuba for reasons of national security if Spain refused to sell the island.

During the mid-1800's, several United States leaders wanted to annex Cuba as a new slave state. In 1854, William L. Marcy, secretary of state under President Franklin Pierce, asked three United States diplomats to make recommendations for the acquisition of Cuba. They were Minister to Spain Pierre Soulé, Minister to France John Y. Mason, and Minister to Britain James Buchanan. They met at Ostend, Belgium, in October 1854.

Newspapers obtained copies of the ministers' dispatch. They called it the Ostend Manifesto and published it in 1855. The implied threat to seize Cuba added to the uproar started in 1854 by the Kansas-Nebraska Act, which made slavery possible in two new United States territories. Pierce took no further action to gain Cuba. But the Ostend Manifesto added to the growing conflict over slavery between the North and the South.

Osteomyelitis, *AHS tee oh MY uh LY tihs,* is an inflammation of bone and *bone marrow,* the jellylike material in the core of bones. Osteomyelitis is caused by infection, usually from a bacterium called *Staphylococcus aureus.* Infection of bone marrow may occur if a person has a compound fracture. In such a fracture, bone marrow may be exposed to air containing bacteria. In other cases, the blood carries bacteria from a boil, from infected tonsils, or from infection somewhere else in the body to the bone marrow. Symptoms of acute osteomyelitis include fever, chills, pain over the infected bone, and nausea. Doctors usually treat the infection with antibiotics. Madison B. Cole, Jr.

Osteopathic medicine, *AHS tee uh PATH ihk,* is a system of medical care based on the belief that all body systems are interrelated. Disease in one part of the body

affects other parts of the body and, therefore, the whole person must be considered in providing treatment. Osteopathic medicine emphasizes the importance of the body's *musculoskeletal system.* This system consists of the muscles and bones and their connecting tendons and ligaments.

Osteopathic medicine involves all aspects of medicine and includes various medical specialties. Osteopathic physicians use all the medical, surgical, immunological, pharmacological, psychological, and hygienic procedures of modern medicine.

The musculoskeletal system makes up 60 percent of the body's weight. Because this system is so extensive, osteopathic medicine maintains that it has especially important interrelationships with other body systems. The musculoskeletal system may be affected by many internal illnesses and, in turn, may speed or worsen the process of disease in other body systems, including the circulatory system and the nervous system. Osteopathic physicians are trained to use osteopathic manipulation of the musculoskeletal system as a diagnostic and treatment tool, when it is appropriate. Such *osteopathic manipulative treatment* (OMT) is a distinctly osteopathic approach to the problems of health and disease.

History. The founder of osteopathic medicine was Andrew Taylor Still, an American medical practitioner. Still announced the basic principles of the osteopathic system in 1874. In 1892, he organized the first osteopathic college, which was established at Kirksville, Missouri.

The first law regulating osteopathic medicine was passed in Vermont in 1896. There are now such laws in all the states, and in some of the provinces of Canada. In every state, graduates of osteopathic medical schools are eligible to be licensed as physicians and surgeons.

Careers in osteopathic medicine. To become an osteopathic physician, a person must complete four years of preprofessional training in an accredited college or university and four years of professional education in an approved osteopathic medical college. The graduate receives a Doctor of Osteopathy (D.O.) degree. There are 15 approved colleges of osteopathic medicine in the United States. After graduating, osteopathic physicians gain additional training by spending a year as an intern in an approved osteopathic hospital. The United States has about 180 osteopathic hospitals, about 130 of which offer intern training programs.

Osteopathic physicians may become certified specialists in any of a number of medical fields. Certification programs require two to five years of additional training after internship. More than 28,000 osteopathic physicians practice in the United States. Most of them are members of the American Osteopathic Association, which has its headquarters in Chicago.

The association publishes two professional periodicals, *Journal of the American Osteopathic Association* and *D.O.* It also publishes the *American Osteopathic Association Yearbook and Directory of Osteopathic Specialists.* Critically reviewed by the American Osteopathic Association

Osteoporosis, AHS *tee oh puh ROH sihs,* is a condition in which bones become abnormally fragile. It is a major cause of pain and disability in older adults. People with osteoporosis have an increased risk of breaking bones throughout their bodies, especially in their wrists, spine, and hips. Breaks may result from minor falls or injuries that would not harm normal bones. Severely affected bones—especially in the spine—may collapse just from the pressure of holding up the body's own weight.

Causes. Osteoporosis occurs as a result of bone loss through a lifelong process called *remodeling* or *bone turnover.* Remodeling is the chief means by which bones repair themselves. In remodeling, certain bone cells remove worn tissue and other cells form new bone. But the amount of new bone falls short of the amount lost by a tiny fraction. As a result, bone density gradually declines after reaching a peak in early adulthood, when a person finishes growing. In osteoporosis, bone density drops below the level needed to keep bones strong and prevent them from breaking.

Many factors can trigger osteoporosis. Some people form less bone than average, due to heredity or inadequate diet. These people may develop osteoporosis as normal bone loss occurs with age. Other people begin with normal bones but have greater than usual bone loss as they grow older. Factors that can cause excessive bone loss include injury, prolonged lack of exercise, and certain hormonal, inflammatory, and digestive disorders.

© SPL from Custom Medical

Healthy bone is strong because the tissue making up its microscopic honeycomblike structures is smooth and dense.

© P. Motta/SPL from Photo Researchers

Bone affected by osteoporosis is weakened by loss of bone tissue, leaving pits in its microscopic honeycomblike structure.

One common form of osteoporosis affects women who have passed *menopause,* the time when menstruation stops. Around menopause, production of the hormone estrogen decreases greatly. Lack of estrogen increases the rate of remodeling, which in turn speeds up the gradual bone loss that accompanies the process.

Prevention and treatment. People need to consume enough calcium and vitamin D to form and maintain healthy bones. Doctors recommend that everyone—especially women—eat three or more calcium-rich servings of dairy products each day. People who cannot eat dairy products can take calcium supplements. Regular exercise also helps keep bones strong.

Certain tests use X rays or sound waves to measure bone density. For people with low bone density, several treatments in addition to diet and exercise help limit further bone loss. Some women who have passed menopause can take medication called *hormone replacement therapy* to supply the body with estrogen or estrogen-like compounds. Scientists have also developed nonhormone drugs that help preserve bone in men and in women who cannot take hormones. Robert Marcus

See also **Bone**; **Hormone replacement therapy**; **Menopause**; **Nutrition** (Minerals).

Osteosclerosis, *AHS tee oh sklih ROH sihs,* means hardening, thickening, and increased density of bone. It may involve part of a bone, a whole bone, or the whole skeleton. The most common form, called *marble bones* or *osteopetrosis,* is a rare inherited disease that occurs in children. In this disease, the bones become excessively dense and thick. This increased thickness fills in the space containing the bone marrow, the tissue that makes red blood cells. As a result, the child develops severe anemia. Bones affected by osteosclerosis become brittle and fracture more easily than do normal bones. Osteosclerosis may develop in part of a bone as a result of an infection or tumor. Madison B. Cole, Jr.

Ostracoderm. See **Fish** (The first fish).

Ostrava, *AW strah vah* (pop. 331,448), is one of the largest cities in the Czech Republic. It lies in the northeastern part of the country (see **Czech Republic** [map]).

Ostrava is the center of the country's largest industrial area. The city is known for its great iron and steel works and its manufacture of metal products. The region also has chemical plants, coal mines, and oil refineries. Other products of Ostrava include food products, furniture, house-building materials, and wearing apparel.

Vojtech Mastny

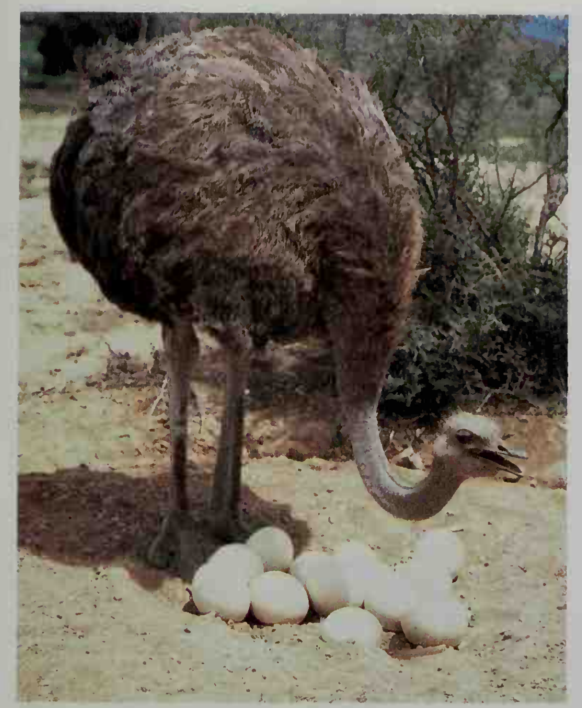
Ostrich is the largest living bird. It may stand nearly 8 feet (2.4 meters) tall and weigh as much as 345 pounds (156 kilograms). Ostriches live on the plains and deserts of Africa. The extinct moas of New Zealand, which were 10 feet (3 meters) tall, were the only birds taller than ostriches. The extinct elephant birds of Madagascar, which weighed about 1,000 pounds (450 kilograms), were the only heavier birds. See **Elephant bird**; **Moa**.

The ostrich is the only bird that has two toes on each foot. The rhea, which is also called the *South American ostrich,* is three-toed and is not a true ostrich. See **Rhea**.

The male ostrich has black feathers on its bulky body, with large white feathers, called *plumes,* on its wings and tail. All the feathers on a female ostrich are dull brown. The ostrich's long, thin legs, upper neck, and small head have almost no feathers. The bare skin ranges in color from pink to blue. Thick black eyelashes surround its eyes, which are almost 2 inches (5 centimeters) in diameter.

The male ostrich has an unusual voice. It gives a deep roar like that of a lion, but with a strange hissing sound. The ostrich cannot fly, but it is known for its speed on the ground. Its long legs can take 15-foot (4.6-meter) steps at speeds up to 40 miles (64 kilometers) per hour.

The ostrich's speed and sharp eyesight help it escape from its enemies, mainly lions, cheetahs, and people. When the ostrich is exhausted and cannot run any farther, or if it must defend its nest, it kicks with its powerful legs. Its long toes, the largest of which is 7 inches (18 centimeters) long, have thick nails that serve as weapons when the bird is cornered. The belief that the ostrich hides its head in the sand when frightened is not true, but stems from the bird's habit of rearranging the eggs in its nest with its bill. From a distance, this appears to cause the ostrich's head to disappear into the sand.



How the ostrich lives. The ostrich usually eats plants, but it will eat lizards and turtles if it can find them. It also eats much sand and gravel to help grind food for digestion. Ostriches drink water when they find it. But they can live for long periods without drinking if the plants they eat are green and moist.

Ostriches are *polygamous*—that is, the male has more than one mate. Each *cock* (male) digs a shallow nest in sand, and from three to five *hens* (females) lay their eggs in the nest. Each hen lays as many as 10 eggs. Each egg is almost round, nearly 6 inches (15 centimeters) in diameter, and weighs about 3 pounds (1.4 kilograms). The

E. R. Degginger

The ostrich is the world's largest bird. Adults stand nearly 8 feet (2.4 meters) tall and may weigh up to 345 pounds (156 kilograms). The male, *shown here,* has black and white feathers.

A female ostrich stands guard over a nest of eggs. Three to five females lay their eggs in the same nest.

eggs are a dull yellow and have large pores and a thick shell.

The male sits on the eggs at night. But during the day the dominant hen—which is usually the oldest hen—helps keep them warm. The eggs hatch in about six weeks. When an ostrich is a month old, it can run as fast as an adult. Ostriches can live to about 70 years of age. Few other birds live so long.

Ostrich farming. Hundreds of years ago, great flocks of ostriches roamed over Africa and western Asia. Arabs in western Asia hunted ostriches for sport, and Africans took their eggs for food or killed the birds for their feathers.

© Anthony Bannister, NHPA

A baby ostrich has spotted down that blends with the ground and helps protect the bird from its enemies.

In the late 1800's and early 1900's, ostrich plumes became popular as decorations on hats and clothing. Large numbers of ostriches were killed for their plumes, and the birds disappeared from Asia and from much of Africa. Ostrich plumes were in great demand and were so expensive that it became highly profitable to raise ostriches in captivity. Plumes could be taken twice a year from live birds kept on ostrich farms. Ostrich farms were established in Africa, Australia, southern Europe, and the United States. But between 1914 and 1918, fashions changed and the market for ostrich plumes dropped sharply.

Today most ostrich farms are in South Africa and Israel, but a few can be found in the United States. Ostriches are now raised primarily for their skin, which provides fine quality leather to make gloves, shoes, and bags. Ostrich eggs and meat are considered great delicacies in some parts of the world. In addition, ostriches are popular zoo animals because of their unusual appearance and usually mild disposition.

Scientific classification. The ostrich is in the ostrich family, Struthionidae. Its scientific name is *Struthio camelus.*

Ostwald, *OHST vahlt,* **Wilhelm,** *VIHL hehlm* (1853-1932), a German chemist, writer, and teacher, won the 1909 Nobel Prize for chemistry. He received the award mainly for his studies in surface phenomena and speeds of chemical reactions. Ostwald wrote one of the early books on electrochemistry. His research on the oxidation of ammonia helped Germany make explosives during World War I (1914-1918). Ostwald was born in Riga, Latvia. Arthur I. Miller

Ostwald process. See Nitric acid.

Oswald, Lee Harvey (1939-1963), was accused of assassinating President John F. Kennedy on Nov. 22, 1963, in Dallas, Tex. Two days later, while millions of television viewers looked on, Oswald was killed. He was shot to death by Dallas night-club owner Jack Ruby, while being transferred from the city jail to the county jail in Dallas. Ruby pushed through a ring of police officers to shoot Oswald down.

No one saw Oswald shoot the President. The high-powered Italian rifle said to have killed the President was traced to Oswald through a Chicago mail-order firm. Oswald worked in the Texas School Book Depository, the building from which the fatal shots were fired. A worker recalled seeing Oswald carry a long narrow package into the building the morning of the assassination. Police captured Oswald, who was armed with a revolver, in a Dallas motion picture theater about 90 minutes after the assassination.

Oswald was also charged with killing police officer J. D. Tippit. Tippit was shot to death in Dallas shortly after the President was killed. But Oswald denied killing either Tippit or the President. A presidential commission headed by Chief Justice Earl Warren investigated the case. After a 10-month investigation, the commission reported in September 1964, that Oswald, acting alone, had killed Kennedy and Tippit. However, a congressional committee later reexamined the evidence and

concluded that Kennedy "was probably assassinated as a result of a conspiracy."

A Dallas jury convicted Ruby of Oswald's murder in 1964. The conviction was reversed in 1966 on the grounds that the trial judge had allowed illegal testimony. A new trial was ordered, but Ruby died in 1967 before the new trial started.

Oswald was born in New Orleans. Investigators said his school and military records showed emotional difficulty. Oswald dropped out of high school at 17 and joined the U.S. Marine Corps. He was discharged in September 1959 and went to the Soviet Union a month later. He tried to become a Soviet citizen but was turned down. He returned to the United States in 1962 with his Soviet-born wife, Marina.

A few people believed that Oswald never returned to the United States. They maintained that a Soviet agent assumed Oswald's identity and killed Kennedy. But in 1981, Oswald's grave was opened, and medical experts identified the body as Oswald's. Carol L. Thompson

Oswego, New York (pop. 17,954), is the easternmost port on the Great Lakes. It lies at the point where the Oswego River empties into Lake Ontario (see **New York** [political map]). The name *Oswego* comes from an Iroquois Indian word meaning *pouring out place.* The city's factories produce rolled aluminum, fabricated steel products, paper products, pumps, and wire. Oswego's Nine Mile Point nuclear power plant generates electricity for several Northeastern states. The city is also home to the State University of New York College at Oswego.

Oswego stands on the site of a British and Dutch fur-trading post founded about 1722. The British controlled Oswego until 1796 and again during the War of 1812. Oswego became a village in 1828 and a city in 1848. With the opening of the Saint Lawrence Seaway in 1959, Oswego became a major world port. It has a mayor-council form of government. John Kenneth White

Otis, Elisha Graves (1811-1861), was an American inventor who built the first elevator with an automatic safety device. The device prevented the elevator from falling if the rope that held the elevator broke. Otis demonstrated his elevator in 1854 in New York City by having the rope cut after he had ascended in the elevator. But his invention did not come into wide use until the rise of the skyscraper in the late 1800's.

Otis was born in Halifax, Vermont. From 1830 to 1851, he held various jobs that developed his mechanical ability. By 1851, he was master mechanic at a firm that made bedsteads. The firm sent Otis to Yonkers, New York, in 1852 to supervise the installation of machinery in a new factory. That year, Otis invented the safety elevator while building an elevator for the factory. Michael M. Sokal

See also **Elevator** (picture).

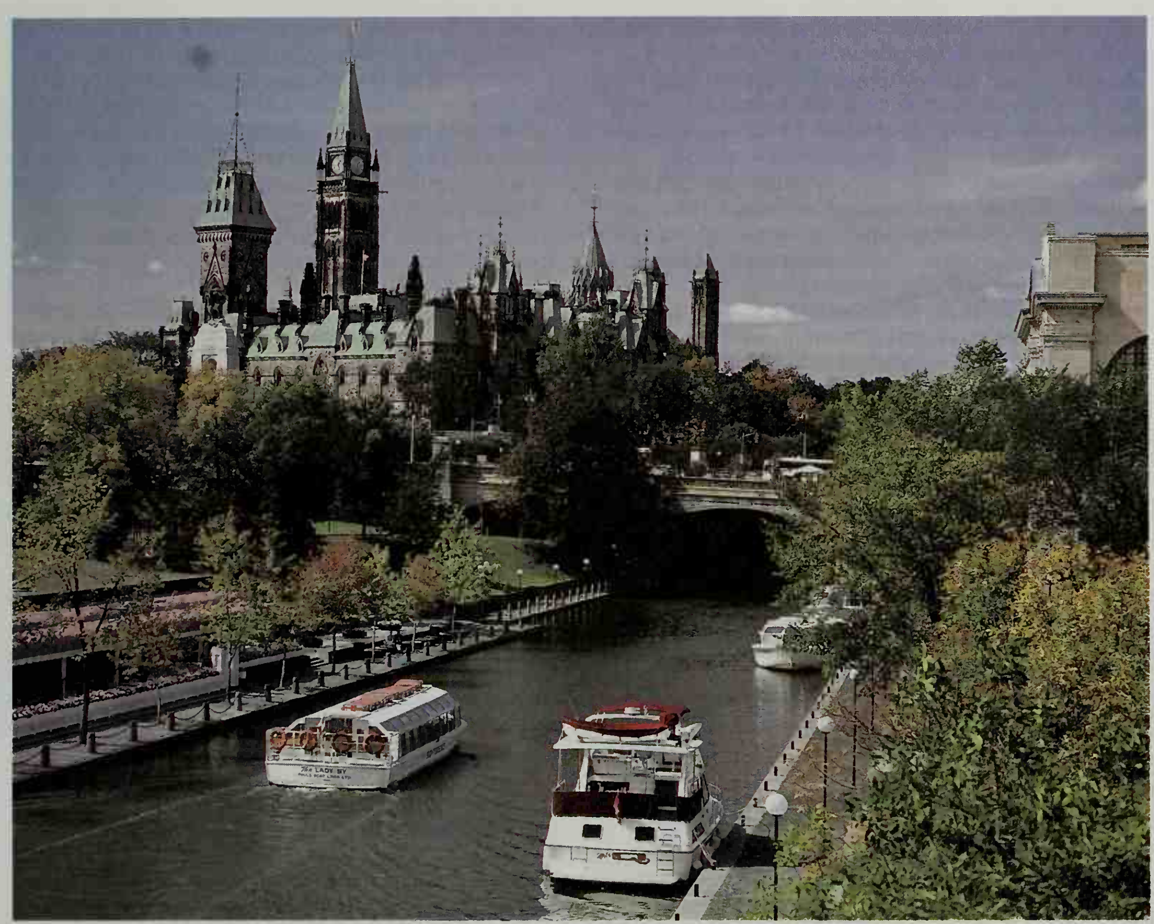
Otis, James (1725-1783), was an American patriot and agitator against the United Kingdom. In 1756, he became the British king's *advocate general* (representative) on the vice-admiralty court at Boston. This court dealt with cases involving the sea and shipping. In 1760, Otis resigned his post in protest over the issuing of new *writs of assistance,* general search warrants that did not name the place to be searched. British authorities wanted to use the writs to catch colonists who smuggled goods into the colonies to avoid paying British trade taxes. Otis argued that the writs violated the British constitution and the laws of nature.

Granger Collection

James Otis was one of the most forceful leaders in the American colonies' struggle for independence from the British.

In 1761, Otis became one of Boston's four representatives in the Massachusetts legislature. There he proposed a meeting of representatives of all the colonies. His suggestion eventually led to the Stamp Act Congress of 1765, in which delegates from nine colonies gathered to consider joint action against the British.

In 1769, Otis was attacked by British revenue officers who resented his criticism of them. A head wound he received during the attack eventually caused him to lose his mind. He was killed by lightning.



Otis was born in West Barnstable, Massachusetts. His sister Mercy Otis Warren was a writer who also became active in the American independence movement. Robert A. Becker

Otoscope is an instrument that doctors use to examine the eardrum. The otoscope consists of a magnifying lens and a light that is powered by a battery. The light illuminates the eardrum and the lens magnifies it about six times. The otoscope makes it possible for the doctor to see changes in the eardrum resulting from infections and diseases. Frank E. Musiek

WORLD BOOK photo by Dan Miller

An otoscope makes it possible for a physician to examine the eardrum of a patient.

Ottawa, the capital of Canada, lies along the Ottawa River. The Rideau Canal joins the river near the slopes of Parliament Hill. The green-roofed Parliament buildings stand atop the hill.

Ottawa, *AHT uh wuh,* Ontario, is the capital of Canada. It lies on gently rolling hills along the south bank of the Ottawa River, about 110 miles (175 kilometers) west of Montreal. Attractive parks, stately government buildings, and scenic drives add beauty to the city. Ottawa faces the city of Gatineau, Quebec, across the Ottawa River.

Parliament Hill, the site of Canada's Parliament buildings, borders the Ottawa River and offers a dramatic view of the heart of Ottawa. It has wooded slopes and beautiful lawns. The Peace Tower, a memorial to Canada's war dead, dominates the hill. The memorial rises 292 feet (89 meters).

In 1826, British troops founded the first settlement in the area that is now Ottawa. The soldiers had come to build the Rideau Canal, which links the Ottawa River and Lake Ontario. The town that sprang up around the construction site became known as Bytown. In 1855, the townspeople changed its name to *Ottawa,* adapted from the Indian word *Outaouak.* The Outaouak were Algonquin Indians that settled and traded furs in the area.

Ottawa was a small lumbering town when Queen Victoria chose it in 1857 to be the capital of the United Province of Canada. The Dominion of Canada was established in 1867, with Ottawa as its capital. The city's layout has been greatly changed through the years in keeping with Ottawa's standing as a national capital.

Metropolitan Ottawa

The city of Ottawa covers 1,073 square miles (2,779 square kilometers), more than 90 percent of which is rural area. The Rideau River flows through Ottawa from the south. It plunges 37 feet (11 meters) over a cliff into the Ottawa River at the northeastern end of the city, forming the Rideau Falls. The Rideau Canal cuts through the city on its way from the Ottawa River to Lake Ontario (see **Rideau Canal**).

Parliament Hill borders the Ottawa River just west

Facts in brief

Population: 774,072. *Metropolitan area population*—1,063,664.
Area: 1,073 mi² (2,779 km²). *Metropolitan area*—2,053 mi² (5,318 km²).
Climate: *Average temperature*—January, 20 °F (−6.4 °C); July, 69 °F (21 °C). *Average annual precipitation* (rainfall, melted snow, and other forms of moisture)—34.24 in (86.97 cm). For the monthly weather in Ottawa, see **Ontario** (Climate).
Government: Mayor-council. *Terms*—3 years for the mayor and 21 council members.
Founded: 1826. Incorporated as a city in 1855.

of the canal. The graceful spires and green roofs of the three Parliament buildings rise above a bluff near the river. The Peace Tower, topped by a lighted clock, stands out above the buildings. The Peace Tower houses a carillon of 53 bells that weigh a total of 60 tons (54 metric tons).

The areas immediately to the west and east of the Rideau Canal are the oldest parts of Ottawa. The city's chief shopping districts center around the Sparks Street Mall to the west of the canal and Byward Market and Rideau Street to the east.

Ottawa includes the urban and rural areas that, until Jan. 1, 2001, had been part of the region of Ottawa-Carleton and the municipalities of Cumberland, Gloucester, Goulbourn, Kanata, Nepean, Osgoode, Rideau, Rockcliffe Park, Vanier, and West Carleton. The Ottawa metropolitan region also includes the Outaouais, an area in western Quebec directly across the Ottawa River from Ottawa. The main city in the Outaouais is Gatineau. It consists of five former Quebec municipalities—Aylmer, Buckingham, Gatineau, Hull, and Masson-Angers—that merged on Jan. 1, 2002.

A visitor's guide

Millions of tourists visit the Ottawa-Gatineau area yearly. They come to see Parliament in action and to view such attractions as the Peace Tower and the eight locks of the Rideau Canal. Ottawa's annual festivals and fairs, its many museums, and the Casino du Lac-Leamy also attract many visitors to the area.

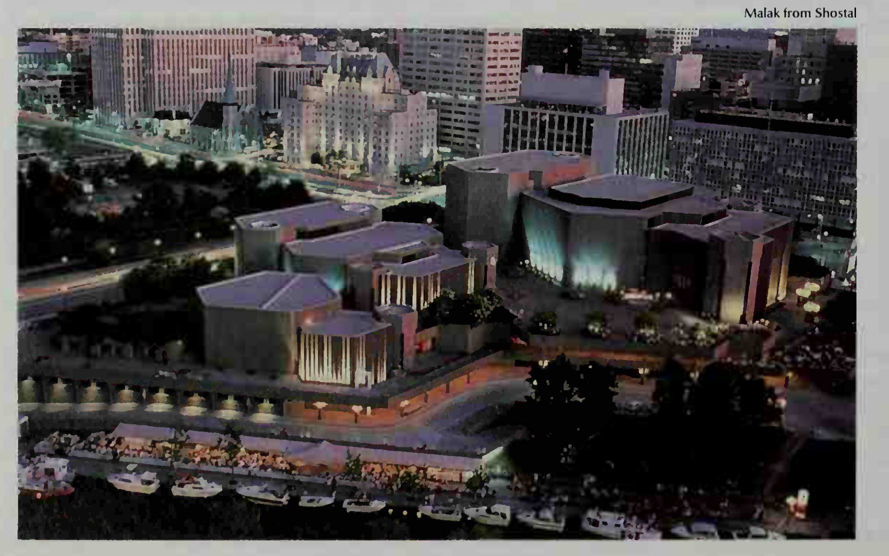
Following are brief descriptions of some interesting places and cultural attractions in Ottawa.

The Parliament buildings rank as Ottawa's most popular tourist attraction. These three buildings—the Centre Block, the East Block, and the West Block—form three sides of a 35-acre (14-hectare) square.

The Prince of Wales, who later became King Edward VII of the United Kingdom, laid the first stone of the Centre Block in 1860. The three buildings were completed in 1865. Fire destroyed most of the Centre Block in 1916, and only the eight-sided Library of Parliament remained. After being rebuilt along the lines of the earlier structure, the Centre Block reopened in 1920.

The Centre Block includes the House of Commons, the Senate chamber, the Peace Tower, and offices of members of Parliament. Canada's prime minister has an office in the East Block. The West Block contains offices for some members of Parliament and other government officials. During July and August, the Governor General's Foot Guards and the Canadian Grenadier Guards perform a daily changing-the-guard ceremony in front of the Peace Tower.

Other government buildings include the Royal Canadian Mint, where visitors may watch coins being made. The National Library and Public Archives building exhibits historical documents. The Canadian Supreme Court building also attracts many visitors.



Rideau Hall, also called Government House, is the official residence of the Canadian governor general. It stands near the mouth of the Rideau River. Thomas McKay, a lumberman, built it in 1838. The Canadian government bought this gray limestone building in 1868 for Viscount Monck, the first governor general. The home of the prime minister is nearby.

The National War Memorial, at Confederation Square, honors the Canadians who died in action during World Wars I and II. It consists of bronze figures of servicemen and servicewomen marching through a granite arch.

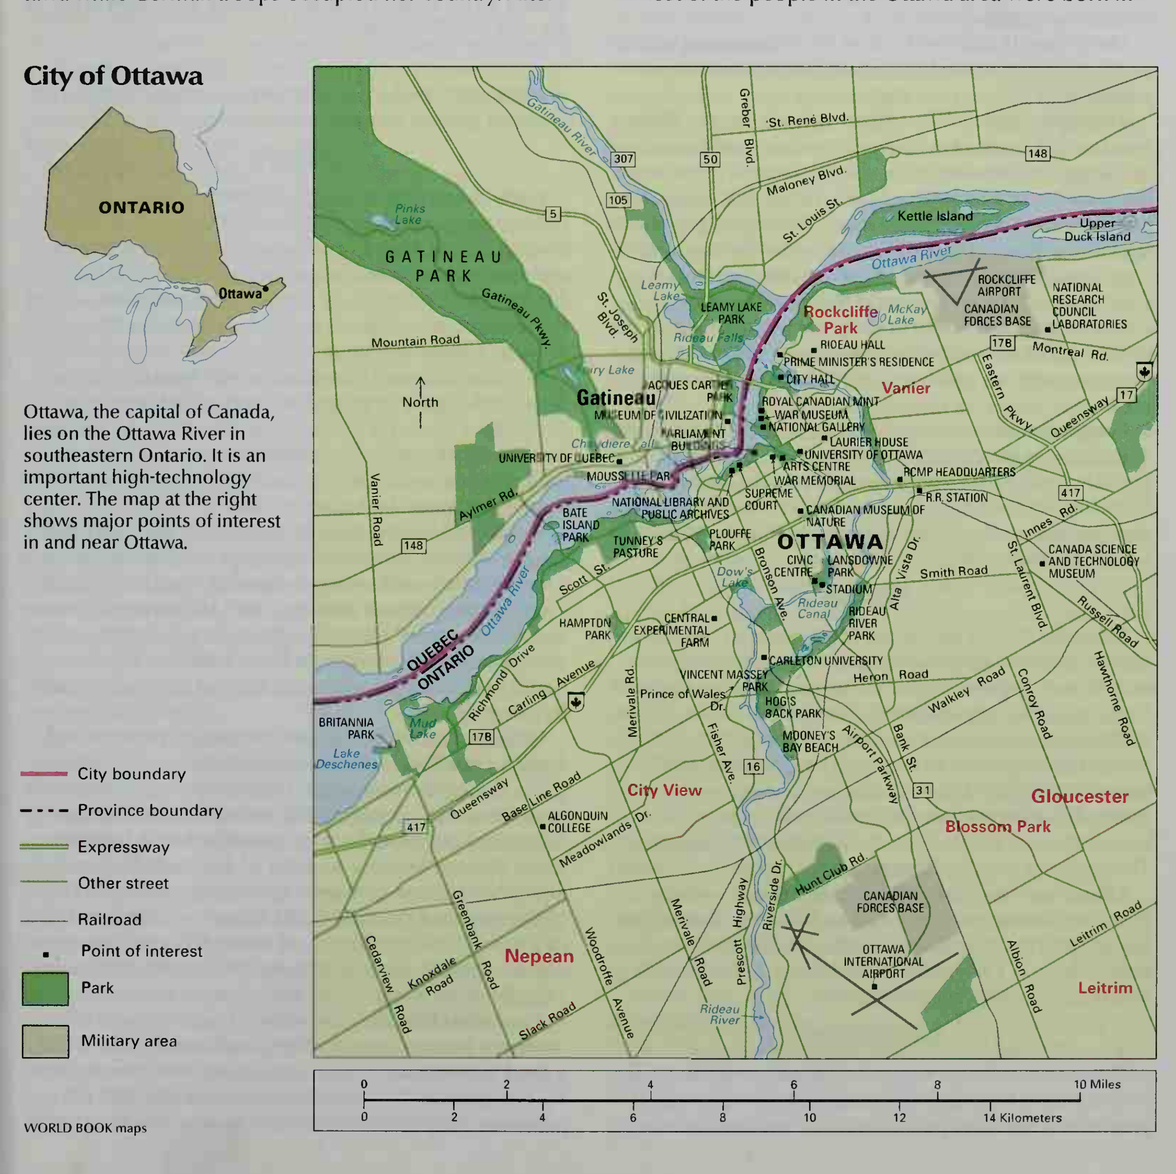
The National Arts Centre, in the heart of Ottawa, opened in 1969. This structure houses a 2,300-seat opera and concert hall, a theater with 800 seats, and a smaller theater with 300 seats. The National Arts Centre Orchestra performs in the concert hall.

Museums. The National Gallery of Canada has Canadian and European paintings and sculpture. In addition, it regularly hosts special exhibitions of international artists. The Canadian Museum of Nature features minerals, animals, and fossils. The Canada Science and Technology Museum has Canadian aircraft. Laurier House, the former residence of Canadian Prime Ministers Sir Wilfrid Laurier and W. L. Mackenzie King, has been pre-

Malak from Shostal

The National Arts Centre stands in a landscaped area in the heart of downtown Ottawa. The facility houses a 2,300-seat opera and concert hall and two smaller theaters.

served as a historical museum. The Canadian War Museum houses the most extensive military collection in Canada. At the Canadian Museum of Civilization, exhibits trace Canada's development from the Vikings to the present and illustrate the cultures of Inuit (formerly called Eskimos) and Indians. This museum is located in nearby Gatineau, Quebec.



Parks and recreation. The Ottawa region has more than 7,980 acres (3,230 hectares) of parks and playgrounds. The Ottawa Senators of the National Hockey League play in the Corel Centre in the community of Kanata. The Central Experimental Farm and the Dow's Lake area include many attractive gardens.

Annual events in Ottawa include the 10-day Canadian Tulip Festival in May. More than 3 million tulip bulbs bloom in parks, along roadways, and on the grounds of public buildings. Former Queen Juliana of the Netherlands sent the bulbs as a gift to Ottawa. During World War II (1939-1945), Juliana, then a princess, lived in Ottawa while German troops occupied her country. After returning home, she sent Ottawa 100,000 tulip bulbs in gratitude for the city's hospitality and for Canada's role in freeing her country. Juliana sent Ottawa 15,000 tulip bulbs for the festival annually until her abdication in 1980. Since 1980, the government of the Netherlands has continued to send the tulip bulbs for the annual festival.

Ottawa holds a winter festival called Winterlude over three weekends in February. The festival features snow sculptures and ice carvings and such sports as broomball, ice skating, and dog-sled racing. The Franco-Ontarian Festival, held in the city every June, celebrates the French-Canadian culture of Ontario. Its features include art exhibits and folk dancing. Every August, the Central Canada Exhibition at Lansdowne Park offers agricultural, industrial, and scientific exhibits. The city's jazz, blues, and folk festivals, which are held in the summer, are also popular.

People

Most of the people in the Ottawa area were born in

Ottawa, the capital of Canada, lies on the Ottawa River in southeastern Ontario. It is an important high-technology center. The map at the right shows major points of interest in and near Ottawa.

Canada. Most of the rest immigrated from Asia, Western Europe, or the United States.

A majority of the people in the Ottawa area have some British or French ancestry. About three-fifths of the residents of Ottawa speak English as their first language. French is the first language of approximately one-sixth of the population.

Economy

Industry and commerce. The Canadian government ranks as Ottawa's largest employer. More than 72,000 of the Ottawa area's residents work for the Canadian government.

The Ottawa area is also a high-technology center and is sometimes called Canada's Advanced Technology Capital. More than 800 high-technology companies employ more than 48,000 people in the Ottawa area. These companies specialize in advanced research and development in a number of fields, including computer software, environmental technology, space science, and telecommunications.

More than 18,000 residents of the Ottawa area work in health care and related industries. Tourism is also an important part of the area's economy.

Transportation. Many major airlines use the Ottawa MacDonald-Cartier International Airport, and passenger and freight trains also serve the city. Ottawa has a fine highway system, including scenic drives that run parallel to the Rideau Canal on both sides. The highway system extends across the Ottawa River into the Gatineau Hills. Two city-owned bus companies provide local service. Four vehicle bridges connect Ottawa with Gatineau.

The Ottawa River links the city with Montreal, and the Rideau Canal connects it with Kingston, Ontario. But water transportation plays only a small part in Ottawa's economy.

Communication. Ottawa has three daily newspapers. The *Ottawa Citizen* and the *Ottawa Sun* are printed in English, and *Le Droit* is printed in French. Four local television stations broadcast in Ottawa, three in English and one in French. Of the 16 radio stations in Ottawa, 14 broadcast in English and 2 in French.

Education

Schools. Ottawa has about 280 elementary and secondary schools, almost evenly divided between public and Roman Catholic institutions. The city is the home of Carleton University and the University of Ottawa. About 18,000 students attend Carleton, and more than 25,000 attend the University of Ottawa. The University of Ottawa, founded in 1848 as the College of Bytown, offers most of its courses in both English and French. St. Paul University and the Dominican College of Philosophy and Theology are also in Ottawa.

Libraries. The Ottawa Public Library has several branches throughout the city. In addition to books, the library carries many films and other audio and visual aids. Ottawa is also home to the Library of Parliament and the National Library of Canada.

Government

Ottawa has a mayor-council form of government. The voters elect a mayor and 21 council members to three-year terms. Taxes on property, sales, and businesses provide most of the government's revenue. Ottawa also receives federal and provincial grants.

Malak from Shostal

Sparks Street Mall, in downtown Ottawa, is the heart of one of the city's chief shopping districts.

History

Early days. Centuries ago, Algonquin and Iroquoian Indians traveled down the Ottawa River on hunting and trading trips. They went ashore at what is now Ottawa and carried their canoes around the Chaudière Falls. In 1613, the French explorer Samuel de Champlain passed through the area. French fur traders used the Ottawa River as a route to the west.

In 1800, Philemon Wright, a farmer from Massachusetts, took over a large tract of land on the north side of the Ottawa River. He built a sawmill and began a lumber business that grew into a thriving industry. Ira Honeywell, the first settler on the south bank, began to farm on the Ottawa side of the river in 1811.

Bytown. After the War of 1812, the British feared another war with the United States. As a result, they sought a way to send gunboats and supplies from Montreal to Lake Ontario without passing near U.S. territory. To carry out this project, the British sent the Royal Engineers under Lieutenant Colonel John By to build the Rideau Canal. A community known as Bytown grew up around By's headquarters.

Frequent conflicts between Irish canal workers and French-Canadian lumbermen made Bytown a stormy place during its early years. The lumber trade on the Ottawa River had begun in 1806, when Wright took the first raft of processed timber down to the St. Lawrence River. Bytown became a center of this trade. Sawmills and other lumber industries sprang up and, by 1837, the population had reached 2,400. Bytown was incorporated as a town in 1850. It became a city in 1855, and the people changed its name to Ottawa. The community had a population of about 10,000 that year.

Capital of Canada. Upper and Lower Canada (the southern parts of present-day Ontario and Quebec) joined in 1840 and formed the United Province of Canada. For the next 17 years, the legislature debated the question of a permanent capital. Meanwhile, Kingston,

Montreal, Quebec, and Toronto each served as capital. Canada referred the decision to Queen Victoria in 1857, and she chose Ottawa because of its beauty and location. Ottawa lay on the boundary of what had been Upper and Lower Canada. Yet the city was far enough from the United States to protect it from attack.

In 1867, Ottawa became the capital of the newly formed Dominion of Canada. Its population had then reached 18,000. The city grew in a disorganized fashion, with numerous railroads crisscrossing through the center of town to accommodate the lumber trade. In 1896, Prime Minister Wilfrid Laurier called for a beautification program to make Ottawa the "Washington of the North." Three years later, the Ottawa Improvement Commission was formed to carry out this project.

The 1900's. In 1900, a great fire destroyed many houses, leaving a large number of Ottawa's 60,000 people homeless. But by 1912, the city had been rebuilt and its population had reached 90,000.

The Federal District Commission replaced the Ottawa Improvement Commission in 1927. Ten years later, Prime Minister W. L. Mackenzie King appointed Jacques Gréber, the Paris city planner, to replan Ottawa. But World War II broke out in 1939 and interrupted the project and Gréber returned to France. Ottawa became the center of Canada's war effort.

After the war, Gréber went back to Canada. In 1951, Parliament accepted his plan to beautify Ottawa. The Gréber Plan brought about significant changes. Ottawa removed 32 miles (51 kilometers) of unattractive railroad tracks and relocated the railroad station to the east edge of the city. It set aside land for a belt of parks around the capital. The commission also developed 88,000-acre (35,600-hectare) Gatineau Park just north of Ottawa. Instead of grouping all government offices in one area, the plan called for new government buildings on the outskirts of the city.

The National Capital Commission replaced the Federal District Commission in 1959. The new commission has the responsibility of acquiring land for beautification purposes. It set up a national capital region of 1,800 square miles (4,660 square kilometers)—one 900-square-mile (2,330-square-kilometer) area in Ontario and another in Quebec. In the 1960's and 1970's, the commission created beaches and parkways within the capital region. At the same time, the area's rapidly growing computer software and electronics industries built research facilities and factories.

In 1962, Ottawa established the Commercial and Industrial Development Corporation—now the Economic Development Corporation—to promote economic growth in the capital. This government corporation created 12 industrial parks in Ottawa during the late 1960's and early 1970's.

In 1973, the city repealed a law that had limited the height of buildings in the downtown area. As a result, larger buildings began to be constructed in Ottawa. City leaders predicted that the additional apartment dwellers and office workers in the new buildings—along with commuters from the growing suburbs—would strain Ottawa's transportation system. The provincial government announced a plan to avoid this problem by helping the city government build a new bus system. Much of the system is reserved for buses only. The plan called for Ontario to pay 75 percent of the cost of the project. Construction of the system began in 1981, and new parts are continually added.

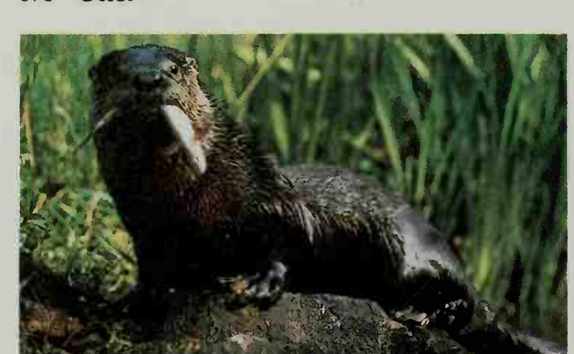
In 1999, the Ontario legislature passed a law to create a new, enlarged city of Ottawa. The new city came into being on Jan. 1, 2001. It includes the urban and rural areas that had been part of the region of Ottawa-Carleton and the municipalities of Cumberland, Gloucester, Goulbourn, Kanata, Nepean, Osgoode, Ottawa, Rideau, Rockcliffe Park, Vanier, and West Carleton. Alje H. Kamminga

Ottawa, University of, or Université d' Ottawa, is a coeducational school in Ottawa, Canada. It is supported by the province of Ontario. It was operated by the Roman Catholic Oblates of Mary Immaculate until 1965, when control was transferred to an independent board of governors. The university's administration, instruction, and research are conducted in French and English. The university has *faculties* (colleges) of administration, arts, education, engineering, health sciences, law, medicine, science, and social sciences. In addition, the university also has a school of graduate studies, which offers 79 programs.

The University of Ottawa was founded as the College of Bytown in 1848. It received a civil charter in 1866 and a papal charter in 1889. In 1965, its faculties of theology and canon law were grouped to form Saint Paul University, which is federated with the University of Ottawa.

Critically reviewed by the University of Ottawa

Ottawa River is the chief branch of the St. Lawrence River and one of the most important streams of Canada. Great quantities of lumber float down the Ottawa from forests in the north.



The river begins in Quebec, about 160 miles (257 kilometers) north of the city of Ottawa. For location, see **Quebec** (terrain map). It flows west to the Quebec-Ontario border, and forms the border as it flows southeast. The city of Ottawa, Canada's capital, stands along the river. The river ends its 696-mile (1,120-kilometer) course north of Montreal, where it empties into the St. Lawrence River.

Rapids and falls along the river make it unnavigable for large ships. But the rapids and falls develop 1.5 million kilowatts of electric power a year. Chaudière Falls, north of the city of Ottawa, is the largest waterfall on the river.

Dams and slides for large logs have been built on the Ottawa to aid the lumber industry. Canals built along the river once aided shipping. But they are now used only for pleasure boats. The Rideau Canal system connects the Ottawa River with Lake Ontario. The river was an early canoe route to the interior of Canada. The French explorer Samuel de Champlain explored the river during the early 1600's. Roger Nadeau

Otter is a member of the weasel family. Otters live close to water and spend much time in it. They are expert swimmers and divers and can stay underwater for three or four minutes. The animal moves awkwardly on land.

Otters live on all the continents except Australia and Antarctica. Most otters weigh from 10 to 30 pounds (4.5 to 14 kilograms) and grow from 3 to $4\frac{1}{2}$ feet (0.9 to 1.4 meters) long, including the tail. The *giant otter* of South America may measure up to 7 feet (2 meters) long. Otters live along rivers, streams, lakes, and coastal waters,

Hans Reinhard, Bruce Coleman Ltd.

The North American otter lives in burrows along the banks of rivers and feeds primarily on fish and crayfish. The animal is a swift and graceful swimmer but moves awkwardly on land.

or in marshes. This article is about otters that live in fresh waters. For information about *sea otters,* which live in the Pacific Ocean, see the article on **Sea otter**.

Body. An otter has a small flattened head; a long, thick neck; and a thick tail that narrows to a point. Special muscles enable the animal to close its ears and nostrils tightly to keep water out. Elastic webbing grows between the otter's toes. In most species, the webbing is extensive enough to help the animals swim swiftly.

Otters, like beavers and muskrats, have long coarse *guard hairs* that cover and protect the short, thick underfur. This underfur traps air and keeps the otter's skin dry. In some species, a layer of fat under the skin insulates the otter from the cold. An otter's fur varies in color from brownish-gray to dark brown when dry, and appears darker when wet.

Otters often use their paws to handle objects. They hold and play skillfully with such things as stones and small shellfish. Some African and Asian species that have only a little webbing between their toes can use the toes like fingers. Such *clawless* and *small-clawed otters* handle food in much the same way as raccoons. These otters feed on shellfish that live in shallow water. All otters have claws. Even the so-called clawless otter has short claws on the three middle toes of its hind feet.

The life of an otter. Otters eat crayfish, crabs, and fish. Although otters can sometimes catch such swift-swimming fish as trout, they generally capture slower fish. They also eat clams, frogs, insects, snails, snakes, and, occasionally, waterfowl. Otters are active the year around. Where people hunt them, they move about more at night than during the day. They hunt mostly alone, but sometimes they hunt in family groups.

Otters spend much time playing. They wrestle and romp and slide down steep muddy slopes in summer and down icy riverbanks in winter. Otters use a variety of sounds to communicate among themselves. All species have a warning growl. In addition, otters use various kinds of chirps, chuckles, screams, and squeals to express their feelings to other otters.

Most otters make their homes in burrows in riverbanks or under rocky ledges, or in abandoned dens of other animals. Most female otters give birth to two or three young at a time. The babies, called *cubs* or *pups,* are born blind. The young do not swim until they are several months old. People hunt otters for their valuable and beautiful fur. Certain species, especially the giant otter, are in danger of becoming extinct.

Scientific classification. Otters belong to the weasel family, Mustelidae. The North American otter is *Lutra canadensis.* The giant otter is *Pteronura brasiliensis.* The clawless and small-clawed otters form genus *Aonyx.* The clawless otter is classified *A. capensis.* The small-clawed otter is classified *A. cinerea.*

Joseph A. Davis

Otter hound is a breed of dog that was developed in Britain for the sport of hunting otters. It has a thick, rough coat, with an oily undercoat that enables it to stay in cold water for long periods. Its feet are slightly webbed, which helps make the dog a good swimmer. A male otter hound stands about 24 to 27 inches (61 to 69 centimeters) high at the shoulder, and weighs from 75 to 115 pounds (34 to 52 kilograms). Females stand about 22 to 26 inches (56 to 66 centimeters) high and weigh 65 to 100 pounds (29 to 45 kilograms). The otter hound's color ranges from grizzled blue and white to sand, with black and tan markings.

The breed probably originated during the 1300's. Its ancestry is unclear, but many breeders believe the otter hound was developed from the Vendee hound of France. Others believe it originally came from the bloodhound. Critically reviewed by the American Kennel Club

Joyce R. Wilson

The otter hound is a hardy dog and a good swimmer.

Otto I (1815-1867), was the first king of Greece after the Greeks won their independence from the Ottoman Empire (now Turkey) in 1830. France, Britain, and Russia—who had helped Greece win independence—named Otto king in 1832, and he ruled from 1832 to 1862. Otto was an unpopular ruler. He failed to move toward the realization of the "Great Idea," which sought to liberate all Greeks still under Ottoman rule in such territories as Crete, Thessaly, and Macedonia.

Otto and the Greeks were prepared to join the Russians against the Ottoman Turks during the Crimean War (1853-1856). Britain and France sent troops to Greece to prevent it. The Greeks blamed Otto for this failure and deposed him in 1862. During his reign, Otto rebuilt Athens, established the first Greek university, and refounded Sparta. Otto I was born in Salzburg, Austria, as Otto Friedrich Ludwig, a prince of Bavaria (now part of Germany). John A. Koumoulides

See also **Greece** (Otto I).

Otto I, the Great (912-973), a German king, was the first emperor of what became known as the Holy Roman Empire. He followed his father, Henry I, as king of Germany in 936. Otto's father had actually ruled only his own duchy of Saxony, but Otto tried to rule all Germany.

In 951, Otto crossed the Alps and declared himself the king of Italy. He was forced to return to Germany when the other German princes began a series of revolts. At the same time, the Slavs in Poland and Bohemia revolted, and the Magyars, or Hungarians, invaded Germany. Otto crushed the Magyars in the battle of the Lech River in 955. The Poles and Bohemians were forced to accept his rule. Otto was able to replace most of the rebellious German princes with members of his own family. The young king of Arles, or Burgundy, also had to accept German rule. Otto then turned his attention toward Italy. He married the widow of an earlier Italian king and defeated a rival for the throne. In 961, Otto crossed the Alps to put down an uprising in Rome. For this service, Pope John XII crowned him emperor of what was later known as the Holy Roman Empire. Otto was born in Quedlinburg. Jonathan W. Zophy

See also **Holy Roman Empire**.

Otto II (955-983), a German king, was the second emperor of what became known as the Holy Roman Empire. He succeeded his father, Otto I, also called Otto the Great, in 973. Otto II's claim to the throne was challenged by his powerful cousin Henry the Wrangler, Duke of Bavaria. But by 978, Otto had defeated Henry and had named an ally to replace Henry as duke.

Otto II defended his borders against Slavs to the east, Danes to the north, and the French to the west. Beginning in 980, Otto II tried to extend his power into southern Italy. Muslims also were seeking control of the region at that time, and they defeated Otto near Crotone in 982. Danes and Slavs in the northern part of the empire then revolted and regained lands that they had lost to Otto I.

Otto II was born in Saxony. Along with his mother, Adelaide, and his wife, the Byzantine princess Theophano, he promoted the arts and church reform. After Otto II's death, Adelaide and Theophano ruled on behalf of his infant son, Otto III. Jonathan W. Zophy

Ottoman Empire was the most powerful empire in the world during the 1500's and 1600's. At its height, it controlled what is now Turkey and parts of northern Africa, southwestern Asia, and southeastern Europe. The empire began about 1300 and lasted until 1922. The Ottomans were nomadic Turkish tribes that migrated to the Middle East from central Asia. The term *Ottoman* comes from *Osman,* also called *Othman* or *Uthman,* the founder and first *sultan* (ruler) of the empire.

Before the arrival of the Ottomans, the Byzantine Empire had occupied parts of Asia Minor (now Turkey) and southeastern Europe for almost 1,000 years. That empire ended in 1453, when the Ottomans conquered the Byzantine capital of Constantinople (now Istanbul). They made the city their capital. By the mid-1500's, the Ottomans ruled Asia Minor, the Balkans, and parts of northern Africa and present-day Iran, Saudi Arabia, and Syria. The Ottomans were Muslims, and they spread their religion, Islam, throughout the empire.

The Ottoman Empire slowly declined only after 1700, when it was faced with the emerging powers of Europe. When World War I began in 1914, the Ottoman Empire consisted of only Asia Minor, parts of southwestern Asia, and part of the Balkans. The Ottomans were defeated in the war, and the empire came to an end in 1922.

Ways of life

People of the Ottoman Empire, in addition to Turks, included many Arabs, Armenians, Greeks, and Slavs. The official language was Ottoman Turkish. The empire had two classes of people. The ruling class paid no taxes and included the imperial family, owners of large estates, and military and religious leaders. The rest of the people were peasants and craftworkers who did pay taxes. The sultan was responsible for protecting them against invasion and abuse by his ruling class. The profession and status of most individuals could be determined by the color and style of clothing and the size of the turban or other headdress they wore.

Almost all the women of the Ottoman Empire lived restricted lives. Islamic law permitted a man to have as many as four wives at a time. Muslim women lived most of their lives in seclusion, usually in a separate section of a household. This section was called a *harem* (see **Harem**). Some women gained power within their harem and had great influence over their husbands and sons. Muslim women also were required to wear veils in public. Many similar restrictions affected non-Muslim women as well.

Most Muslims strictly followed the rules of Islam as set down in their holy book, the Quran (see **Islam** [Teachings and practices]). However, the Ottomans allowed all religious groups to practice their own faiths. Christians and Jews made up the largest non-Muslim groups. Each religious group, including the Muslims, formed a *millet* (nation), whose leader represented its members before the government.

Cultural life. Neighborhood *mosques* (Muslim houses of worship) served as both religious and social centers for Muslims. Other millets had their own religious ceremonies and social events. The Ottomans adopted many styles of Byzantine and Persian art and literature. Major Ottoman contributions came in the fields of architecture, carpet weaving, and tile making.

Ottoman education emphasized religious studies. Beginning in the 1300's, boys attended schools in mosques. The best students went on to high schools called *medreses.* Girls began to go to elementary school in the mid-1800's. *Secular* (nonreligious) education at the high school and university levels began about the same time.

Economy. Most of the people of the Ottoman Empire worked as farmers. Grain was grown in fertile areas of Egypt, Syria, and lands surrounding the Black Sea. Craftworkers and merchants practiced their trade in the cities and towns.

The Ottoman Empire gained great wealth through trade. Some of the busiest trade routes between Asia and Europe ran through the empire. Merchandise offered in the markets of Ottoman cities included Chinese porcelains, European woolens, Persian silks, and spices from Asia.

Government. The Ottoman sultans made all important governmental decisions for the empire. The sultans appointed officials to collect taxes and to keep peace

within the empire. The powers of the sultans were limited. For example, the rulers needed the support of the army to maintain their position. New laws were also subject to the approval of the empire's chief religious judge, the *grand mufti,* before they could take effect.

Until the 1630's, the oldest or favorite son succeeded to the throne upon the death of a sultan. After the 1630's, it became common for the successor to be the oldest surviving male member of the family. Some sultans removed threats to their throne by murdering potential rivals or confining princes to the royal palace.

History

The beginning of the empire. The Turkish tribes led by Osman began to expand their small territory in the northwest corner of Anatolia (now Turkey) during the late 1200's. In 1326, the tribes captured the city of Bursa, which had been part of the Byzantine Empire. In the late 1300's, the Ottomans formed a group of highly trained soldiers called *Janissaries* (see **Janissaries**).

Expansion and decline. By the mid-1400's, the Ottomans had conquered the entire Byzantine Empire except for the city of Constantinople. Ottoman troops, led by Sultan Mehmet II, captured Constantinople in 1453.

Under Mehmet II, or Mehmed II, the Ottomans also conquered much of southeastern Europe and territory near the Black Sea. They took over Syria in 1516 and Egypt in 1517. The empire reached its peak of power and wealth under Sultan Süleyman I, who ruled from 1520 to 1566. His armies conquered Hungary, northern Africa, and territory on the east coast of the Red Sea down to what is now Yemen.

In 1571, naval forces from Spain, Venice, and the Papal States of Italy almost destroyed the Ottoman fleet in the Battle of Lepanto. But the navy was rebuilt, and the empire continued to grow. In 1683, Austrian and Polish troops turned back an Ottoman attack on Vienna, Austria. This defeat ended the empire's territorial expansion.

During the next 200 years, many nations won independence from Ottoman rule. Government corruption, oppressive taxation, inflation, and weak sultans also contributed to the decline of the empire.

The empire ends. In 1908, a group of Ottoman military officers called the Young Turks forced Sultan Abdülhamit II to restore the empire's constitution, which guaranteed an elected parliamentary government. The constitution had been adopted under Abdülhamit in 1876, but he suspended it the next year following a Russian invasion.

After World War I ended in 1918, troops of several Allied nations, including the United Kingdom and Greece, occupied the Ottoman Empire. The empire's forces had supported Germany in the war. A Turkish military hero named Mustafa Kemal (later called Kemal Atatürk) led a nationalist movement that ended the occupation of Turkey in 1922. The Turkish government abolished the Ottoman Empire that year and created the Republic of Turkey in 1923. Virginia H. Aksan

Ouachita River, *WAHSH ih TAW,* begins in the Ouachita Mountains of western Arkansas and flows east and then south into Louisiana. Sometimes called the *Washita,* it is about 605 miles (974 kilometers) long. The Ouachita joins the Tensas River to form the Black River about 25 miles (40 kilometers) west of Natchez, Louisiana. Small barges can sail about 350 miles (563 kilometers) up the river to Camden, Arkansas. During some high water seasons, barges can go about 70 miles (110 kilometers) farther, to Arkadelphia (see **Arkansas** [physical map]; **Louisiana** [physical map]). John G. Hehr

Ouagadougou, *WAH guh DOO goo* (pop. 442,223), is the capital and largest city of Burkina Faso. For the location of Ouagadougou, see **Burkina Faso** (political map). The city has a modern central district and numerous *mosques* (Islamic houses of worship). The palace of the Moro Naba, the traditional leader of the country's Mossi people, is also in the city. Ouagadougou has an airport, a university, and a museum of African art. Its industries include food processing, the bottling of beverages, and the production of building supplies and textiles.

Ouagadougou was probably founded in the 1100's. In the mid-1400's, it became the Moro Naba's capital. French forces captured the city in 1896. It grew little until 1954, when a railroad connected it with Bobo Dioulasso and Côte d'Ivoire. Since then, many people have

The Ottoman Empire started as a small state around Bursa in Anatolia (now Turkey). By the late 1400's, the empire had expanded into eastern Europe.

During the 1600's, it was the world's largest empire. It had its capital in Istanbul and covered parts of Eastern Europe, the Middle East, and North Africa.

WORLD BOOK maps

The empire declined in the 1700's and 1800's and collapsed during World War I (1914-1918). Turkey was formed in 1923 from the remaining territory.

moved to the city in search of work. Samuel Decalo

Ouija board, *WEE juh* or *WEE jee,* is a device used to supposedly ask questions of the spirits of the dead and receive answers from them. People who believe seriously in the Ouija board use it at gatherings called *séances.* Other people use the Ouija board for fun as a game.

A Ouija board has various symbols printed on its surface. These symbols include the letters of the alphabet, the numbers from 1 to 9 and 0, and the words *yes* and *no.* A smaller, three-legged board serves as a pointer.

Two or more people hold a Ouija board on their laps and press their fingers lightly on the pointer. One of them asks a question. The pointer supposedly answers by indicating a word or a number or by spelling out words. According to people who believe in the Ouija board, spirits guide the pointer. Others think the fingers of the questioner influence the pointer. The Ouija board was invented about 1890 by William Fuld of Baltimore. Its name comes from the French word *oui* and the German word *ja,* both of which mean *yes.* Alan Dundes

Ounce. See Snow leopard.

Ounce is a unit of weight or volume used primarily in the United States. As a unit of weight, it is used to measure *mass* (the amount of matter in an object) or force. In commercial and everyday use, the term *weight* is understood to mean mass, and the ounce is used as a unit of mass. In science and technology, *weight* refers to the gravitational force on an object, and so the ounce is also used as a measure of that force.

In the *avoirdupois* system of weights, there are 16 ounces in a pound. As a unit of force, the avoirdupois ounce equals 0.278 newton in the metric system; as a unit of mass, 28.350 grams in the metric system. This ounce also equals 437.5 grains of mass. The *troy weight* system, used throughout the world to measure the mass of precious metals, has a heavier ounce. The troy ounce equals 31.103 grams, or 480 grains. In the troy weight system, there are 12 ounces in a pound.

As a measure of liquid volume, one *fluid ounce* equals 29.574 milliliters. There are 32 fluid ounces in a liquid quart. Michael Dine

Outback is a term that refers to the rural interior of Australia and its unique characteristics. Some people use the term *outback* to describe all thinly populated areas away from Australia's coastal cities. Others apply the term to only those areas with low rainfall. The land and climate in much of the outback are harsh and variable. Many people associate life in the outback with a sense of adventure, individualism, and isolation.

Millions of years of weathering and erosion have flattened the outback's landscapes and reduced the quality of the soil. Most mountains in the region stand less than 3,900 feet (1,200 meters) tall. Large deserts with plant-covered sand dunes stretch across much of the outback. Since the late 1800's, large areas have been used for grazing sheep and cattle. The outback also has rich mineral resources, and mining is an important activity.

The outback is famous for its wide variety of unusual wildlife. The region's plants and animals include spinifex grass and eucalyptus and acacia trees; kangaroos and other marsupials; and large flightless birds called emus.

WORLD BOOK map

The Australian outback, according to some people, refers only to those areas with low rainfall, *shown above.* But others define the outback as all thinly populated parts of the continent.

Less than 10 percent of Australia's people live in the outback. But many Australian Aborigines live there, usually in small, isolated communities or on livestock *stations* (ranches). Outback residents lack easy access to health care and education. As a result, they generally have poorer health and fewer career opportunities than people in the cities. A special aviation service called the Royal Flying Doctor Service provides medical treatment to people in remote areas. Also, schools of the air help students in isolated regions communicate with teachers using radio, telephone, and computer equipment.

The word *outback* comes from the phrase "out in the back country." This saying was first used in the 1800's to describe Australian frontier areas where the British colonial governments had little control. Stuart Pearson

Outcault, *OWT kawlt,* **Richard Felton** (1863-1928), was an American cartoonist. He created the first comic strip that gained widespread popularity. This weekly strip, called "Hogan's Alley," first appeared in 1895 in *The New York World,* a New York City newspaper. The strip quickly became an immense success.

The main character of "Hogan's Alley," a boy named Mickey Dugan, wore a long gown that, beginning in early 1896, was colored yellow. As a result, the character became known as the Yellow Kid. Later in 1896, "Hogan's Alley" was renamed "The Yellow Kid." Still later that year, Outcault accepted an enormous salary from the *New York Journal* to draw the strip for it. *The New York World* hired another artist to draw "The Yellow Kid," and the papers began a sensational rivalry. Other newspapers called them the "Yellow Kid journals." The term *yellow journalism,* meaning a highly sensational kind of newspaper writing, was symbolized by "The Yellow Kid" comic strip. Outcault was born on Jan. 14, 1863, in Lancaster, Ohio. Charles P. Green

Outlaw. See Bandit with its list of *Related articles.*

Outline is a short summary of the main topics or principal ideas of a written work or a speech. A good outline serves as a useful tool for a reader or a writer. A reader can outline written material to discover the structure of the author's argument and to determine its strengths and weaknesses.

A writer uses an outline primarily to organize ideas about a subject. The procedure for making such an outline is the same, whether the outline is short and simple or long and complicated. First, list the important points about the subject. Next, classify the items on the list into meaningful groups. Then decide on a method of organizing the groups to present the information clearly and effectively. For example, move from the least important to the most important points or from arguments in favor of a position to arguments against it.

A formal outline may take the form of a *topic outline* or a *sentence outline.* A topic outline summarizes the chief topics and subtopics of the piece in brief phrases. A sentence outline uses complete sentences for each topic and subtopic. Most formal outlines have a thesis statement that identifies the argument or subject of the outline, followed by topic headings and indented subheadings.

Here is an example of a topic outline:

Thesis statement: There are better reasons for not buying a car than for buying one.

I. Reasons for buying a car
- A. Convenience
- B. Status

II. Reasons for not buying a car
- A. Inconvenience
  - 1. High cost of fuel
  - 2. Increasingly crowded roads
  - 3. Parking a growing problem
    - a. Urban areas unpredictable
    - b. Weather unpredictable
- B. Hazards
  - 1. Highway systems inadequate
  - 2. Possibility of accidents
- C. Poor financial investment
  - 1. Initial investment
    - a. High taxes
    - b. High interest rates
  - 2. Continuing investment
    - a. Fuel
    - b. Equipment
    - c. Maintenance
    - d. Fees to government agencies

Other examples of topic outlines may be found in *World Book* at the end of such articles as **United Kingdom, Bird,** and **American literature.** The **Public speaking** article uses a sentence outline. William E. Coles, Jr.

Outrigger is either of two kinds of boats or two kinds of boat devices. In the Indian and Pacific oceans, an outrigger is a float attached to certain rowing canoes. The canoes are also called outriggers. The float is a long log that runs parallel to the boat and is linked to it by a frame. The float acts as a counterbalance to prevent the canoe from tipping over. A canoe that has two floats, one on each side, is called a *double outrigger.*

In the United States, *outrigger* refers to brackets that extend from the sides of certain small, narrow racing boats called *shells.* The brackets support the oars. The boats that have such brackets are sometimes called outriggers. Octavia N. Cubbins

Outward Bound is an international educational organization that provides challenging wilderness experiences as courses of study. These experiences are intended to contribute to the self-discovery and personal growth of the participants.

Outward Bound offers courses to anyone more than 14 years old and in good health. Most of the courses last from 21 to 26 days and include such activities as backpacking, rock climbing, canoeing, sailing, and cross-country skiing. A small group of people take a course together. Each person, working with the others, must solve various problems in an unfamiliar wilderness environment. Outward Bound believes that dealing with these problems increases a person's self-confidence, self-awareness, and appreciation of others.

The first Outward Bound school was established in 1941 in Aberdovey, Wales, near Aberystwyth. Kurt Hahn, a German educator, founded it as a survival program for British sailors during World War II. The organization's first school in the United States was started in 1962 near Aspen, Colorado. Outward Bound has schools in more than 50 countries, including seven in the United States. Its U.S. headquarters are in Garrison, New York.

Ouzel. See **Dipper.**

Ovarian cancer is uncontrolled multiplication of cells of the *ovaries,* a pair of female sex organs that store and release eggs. The ovaries also secrete *estrogens* and *progesterone,* the female sex hormones. Ovarian cancer occurs most often in women over age 60. The disease is more common among women in developed countries and relatively rare among women in Asia and many Third World countries. A high fat diet, early onset of menstruation, late menopause, never being pregnant, and having a close relative with the disease are all factors that may increase an individual's risk of developing ovarian cancer.

In the early stages of ovarian cancer, when the chance for successful treatment is greatest, the disease causes few or no symptoms. By the time symptoms develop, the cancer is often in a more advanced stage. Symptoms of ovarian cancer include discomfort or a feeling of fullness in the abdomen, loss of appetite, and unusual vaginal bleeding.

If ovarian cancer is suspected, doctors may begin by performing a blood test. Cancers of the ovary may produce a protein called *CA 125,* which can be measured in the blood. Elevated levels of CA 125 occur in about 80 percent of cases of ovarian cancer. In order to make a definite diagnosis, however, physicians must perform a procedure called a *biopsy.* In a biopsy, a surgeon removes a sample of ovary tissue. Experts then examine the tissue with a microscope, looking for cancer cells. If the biopsy reveals cancer, doctors may order additional tests to determine the extent of the disease. These tests include computed tomography (CT) scans of the abdomen and pelvis, and X rays of the chest and other organs.

The treatment for ovarian cancer usually starts with surgical removal of the ovaries and nearby tissues, including the fallopian tubes and often the uterus. The pa-

tient may also receive *chemotherapy* (drugs that kill cancer cells). Patients whose cancer has not spread have an excellent chance of being cured. Physicians often monitor the level of CA 125 in the blood of patients to detect any recurrence of the cancer. Marc B. Garnick

Ovary, *OH vuhr ee,* is either of a pair of female sex organs that store and release eggs. The ovaries also secrete *estrogens* and *progesterone,* the female sex hormones. The human ovary is oval in shape and about the size of an unshelled walnut. One ovary is located on each side of the uterus, at the base of the abdomen.

At birth, each ovary contains about 400,000 immature eggs. About 400 of these eggs will mature and be released during a woman's childbearing years. During the first half of each menstrual cycle, one of the eggs matures. Also during this time, the ovaries release estrogens, which cause the lining of the uterus to thicken in preparation for pregnancy. *Ovulation* (the release of the mature egg) occurs about midway through the menstrual cycle.

After ovulation, the ovary that released the egg secretes progesterone, which maintains the uterine lining, as well as estrogens. If the egg is fertilized, a pregnancy begins. The ovary and *placenta*—an organ that develops early in pregnancy—secrete progesterone and other hormones, and the menstrual cycle stops until after the baby has been born. If the egg is not fertilized, the ovary stops producing progesterone about 14 days after ovulation. The egg and the uterine lining then pass out of the body during menstruation.

Between the ages of 45 and 55, most women stop menstruating and enter a period called *menopause.* The ovaries gradually stop functioning and shrink to about the size of a pea. Lois Kazmier Halstead

Oven. See **Range; Cooking** (Methods; History).

Ovenbird is a common American bird that belongs to the family of warblers. The ovenbird looks like a small thrush. It is about 6 inches (15 centimeters) long and has a brownish olive-green back, dull orange crown, and a white breast spotted with black. Its song sounds like the word *teacher,* repeated with increasing loudness. The ovenbird is often called the *teacher bird.*

WORLD BOOK illustration by Trevor Boyer, Linden Artists Ltd.

The ovenbird is a common North American warbler.

The ovenbird nests from Oklahoma to Georgia, and north to Manitoba and Labrador. Its name comes from the shape of its nest, which looks somewhat like an old-fashioned rounded oven. The ovenbird hides its nest on the forest floor. It lays four to six white eggs, speckled with cinnamon-brown. It eats mostly insects.

Sandra L. Vehrencamp

Scientific classification. The ovenbird belongs to the tribe Parulini in the subfamily Emberizinae, family Fringillidae. Its scientific name is *Seiurus aurocapillus.*

See also **Warbler.**

Overeaters Anonymous is an organization for people whose eating habits disrupt their lives or threaten their health. Overeaters Anonymous uses the term *compulsive overeating* to describe many types of eating problems. For example, some members overeat regularly. Others eat too much, then starve themselves or try to eliminate the excess food from their bodies by vomiting or using laxatives. The organization has members in every weight category, from underweight to overweight.

Overeaters Anonymous considers compulsive overeating an illness that can be managed. Members follow a recovery program adapted from Alcoholics Anonymous. This program encourages personal change through applying spiritual principles to life. Members gain support for their personal commitment by attending as many meetings as they wish. At meetings, members provide one another with fellowship, caring, acceptance, and practical advice. The organization's head office is in Rio Rancho, New Mexico.

Critically reviewed by Overeaters Anonymous

Overture, *OH vuhr chur,* is an instrumental composition that introduces a longer musical work, especially an opera. Some overtures, called *concert overtures,* are always performed as independent compositions.

The first overture was written in the 1660's by the French composer Jean-Baptiste Lully. Lully opened his operas and ballets with *French overtures,* which were short pieces consisting of two sections. The first section was slow, and the second lively. The second section of the overture often ended with a brief return to the slow tempo.

In the 1690's, Alessandro Scarlatti, an Italian composer, developed the *Italian overture,* also called the *sinfonia.* It consisted of three movements, of which the first was lively and written in the sonata form (see **Sonata**). The second was slow, and the third extremely fast. The Italian overture had an important role in the development of the symphony.

Overtures were revolutionized during the 1700's by the German-born Christoph Willibald Gluck and by Wolfgang Amadeus Mozart of Austria. Gluck became the first major composer to use an overture to put the audience in the proper mood for an opera. Previously, the overture had no direct connection with the opera that followed it. Mozart continued Gluck's ideas and established the overture as a single movement. The overtures written by Mozart served as models for overtures to future operas.

During the 1800's, opera overtures were often performed separately at concerts. These performances inspired composers to write concert overtures. Most of these concert overtures were short pieces that musical-

ly told a story or set a mood. Popular concert overtures include the "1812" (1880) by Peter Ilich Tchaikovsky of Russia and the *Academic Festival* (1881) by Johannes Brahms of Germany. During the 1900's, many concert overtures were written to be performed by school orchestras and bands.

The concert overtures composed by Felix Mendelssohn of Germany during the 1820's and 1830's led to the development of the *symphonic poem* in the mid-1800's (see **Symphonic poem**). Another German composer, Richard Wagner, avoided the traditional overture in his operas of the mid-1800's. Instead, Wagner used an orchestral piece called a *prelude* that led directly into the first scene of an opera. Many later composers used neither an overture nor a prelude in their operas.

R. M. Longyear

Ovid, *AHV ihd* (43 B.C.-A.D. 17?), was a great Roman poet. He became best known for his witty and sophisticated love poems.

Perhaps Ovid's most famous work is the *Art of Love,* which is a kind of manual in verse on how to find and keep a lover. It consists of three books, two addressed to men and one to women, and all written in a humorous, satirical style.

Ovid believed that the *Metamorphoses* was his greatest work. It is a narrative poem beginning with the creation of the world and ending in Ovid's time. The poem describes the adventures and love affairs of deities and heroes, with more than 200 tales taken from Greek and Roman legends and myths. Many of the stories involve a *metamorphosis* (transformation), such as the transformation of a woman into a bird. For information about some of the stories, see **Arethusa; Narcissus; Pygmalion;** and **Pyramus and Thisbe.**

Ovid's other poems include the *Heroides (Letters of Heroines)* and the unfinished *Fasti (The Calendar).* The *Heroides* consists of 21 imaginary letters between famous women of mythology and their husbands or lovers. The *Fasti* deals with Roman religious festivals and customs and anniversaries of historical events.

Ovid was born on March 20, 43 B.C., in Sulmona, Italy. His full name was Publius Ovidius Naso. In A.D. 8, Emperor Augustus banished Ovid to an isolated fishing village on the Black Sea. Ovid wrote many poems pleading to return to Rome. But his pleas were ignored, and he died in exile. Elaine Fantham

See also **Latin literature** (The Augustan Age).

Oviparous animal, *oh VIHP uhr uhs,* is an animal that reproduces by means of fertilized eggs that develop outside of the mother's body. In *viviparous* animals, eggs are fertilized and develop inside the parent. Most *vertebrates* (animals with backbones) are oviparous, although there are exceptions. For example, certain types of fish, sharks, lizards, and snakes, and all mammals except for the platypus and the echidna, are viviparous.

George B. Johnson

See also **Viviparous animal.**

Oviraptor, *OH vuh RAP tuhr,* was a small meat-eating dinosaur that resembled an ostrich. It lived in what is now central Asia between 90 million and 65 million years ago.

The dinosaur grew about 6 feet (1.8 meters) long. In many individuals, a bony crest crowned the top of the head. Although *Oviraptor* was a meat-eater, it had a beaked mouth with no teeth. Only a bony peg in the roof of its mouth could have served to stab or crush food. The dinosaur ran swiftly on long hind legs, and it could grasp prey with the large claws on its forelimbs.

Oviraptor was discovered in the 1920's. It received its name, which means *egg robber,* because people believed it primarily ate the eggs of other dinosaurs. Today, however, scientists are uncertain about *Oviraptor's* diet. The dinosaur probably ate shellfish, or possibly small reptiles or eggs.

In 1993, fossil hunters found a nearly complete skeleton of a female *Oviraptor* lying on top of its nest of eggs. This fossil was preserved in exactly the same position as that of a modern bird. The *Oviraptor* sat in the middle of its ring of eggs to keep them warm and protected. This discovery suggested that dinosaurs took better care of their young than previously believed. It also strengthened the view that birds are closely related to certain meat-eating dinosaurs. David B. Weishampel

Owen, Robert (1771-1858), was a Welsh-born social reformer. He tried to prove as a businessman that it was good business to think of the employees' welfare. He set up the famous New Harmony community in Indiana in 1825. Owen also pioneered in cooperative movements (see **Cooperative** [History]).

Owen was part owner and the head of the New Lanark cotton mills in Scotland in 1799. The Industrial Revolution had begun, and machines were replacing home sewing and weaving. New factories were rarely built with the comfort of the workers in mind. Wages were low, and women and children were not treated with consideration.

Owen organized a model community. Instead of employing children, he built schools for them. He kept his mills in good repair and tried to take care of his laborers' needs. His successful mills impressed many visitors.

New Harmony. Owen wrote on the subject of proper social conditions and tried to interest the British government in building "villages of cooperation." He thought these villages ought to be partly agricultural and partly industrial. He made up his mind to show they could succeed. He then bought the town of Harmonie, Indiana, and renamed it New Harmony. There he attempted to create a *utopia* (perfect society).

Owen believed in equal opportunity for all. His ideas in education were influenced by Johann Pestalozzi, a Swiss educator. Owen opposed mere book learning. He believed children also could be taught "correct ideas" by surrounding them with good examples. Owen lost popularity with some people because he held antireligious views.

Many of New Harmony's residents eventually gave up Owen's principles. In 1827, the community failed, and Owen returned to England.

© Hulton/Archive

Robert Owen

Cooperatives. Owen retired from business to concentrate on his social theories. He lived in London in 1828. There, trades unions became interested

in his "villages of cooperation." In 1833, Owen helped organize the Grand National Consolidated Trades Union. It had over 500,000 members. The movement tried to reorganize industry into cooperatives. The government and manufacturers opposed it, and by 1834, the union had collapsed. Owen continued to write and agitate for government aid. Although his plans were not accepted, his ideas influenced all later cooperative movements.

Owen was born on May 4, 1771, in Newtown, Wales. He left school when he was 9 to work as a cotton spinner. Owen's son Robert Dale Owen became a well-known social theorist. David L. Anderson

See also **Kindergarten** (History); **New Harmony; Pestalozzi, Johann H.**

Owen, Robert Dale (1801-1877), was a social theorist and an American legislator. He worked with his father, social reformer Robert Owen, in model communities in Scotland (at New Lanark) and in the United States (at New Harmony, Indiana). He edited the New Harmony *Gazette* with Frances Wright. When the New Harmony community failed in 1827, Owen moved to New York City. He and Frances Wright edited the *Free Enquirer* and tried to organize the Workingmen's Party in 1829 in New York.

Owen returned to Indiana in 1832. He served in the state legislature from 1836 to 1839 and from 1851 to 1852. He was a member of the U.S. House of Representatives from 1843 to 1847. He served as minister to Naples from 1854 to 1858. Owen championed emancipation for black slaves and influenced President Abraham Lincoln's views. He was a freethinker in religion and a pioneer in advocating birth control and universal education. Owen was born on Nov. 9, 1801, in Glasgow, Scotland.

David L. Anderson

See also **New Harmony; Owen, Robert.**

Owen, Ruth Bryan (1885-1954), was the first American woman chosen to represent the United States in another country. She served as U.S. minister to Denmark from 1933 to 1936. The United States did not have an ambassador to Denmark at the time. The first woman to serve as a U.S. ambassador to a foreign country was Eugenie Anderson, when she became ambassador to Denmark in 1949.

Ruth Bryan Owen

Owen was born on Oct. 2, 1885, in Jacksonville, Illinois, the oldest daughter of the well-known statesman, William Jennings Bryan. She served as a Democrat from Florida in the U.S. House of Representatives from 1929 to 1933. Owen served as alternate U.S. representative to the United Nations General Assembly in 1949. Alonzo L. Hamby

Owens, Jesse (1913-1980), was an American track-and-field star. His performances during the mid-1930's in college and in the Olympic Games made him one of the most famous athletes in sports history.

Owens won four gold medals at the 1936 Summer Olympic Games in Berlin, Germany. He won the 100-meter and 200-meter races and the broad jump (now called the long jump), and he was a member of the winning American 400-meter relay team. He set Olympic records in the 200-meter race and in the broad jump. The performance of Owens, who was black, was embarrassing to Adolf Hitler, the ruler of Germany. Hitler and his followers were hoping that German athletes would prove that the *Aryans*—a term they used for Germans and certain other peoples of northern Europe—were superior to all other peoples.

United Press Int.

Jesse Owens

Owens was born on Sept. 12, 1913, in Oakville, Alabama, near Danville. His given and family name was James Cleveland Owens. His nickname, Jesse, came from his initials, J. C. Owens was the son of a sharecropper. At the age of 7, he moved with his family to Cleveland. Owens excelled in track and field while attending Ohio State University from 1933 to 1936. At a college meet in Ann Arbor, Michigan, in 1935, he broke three world records and tied a fourth within 45 minutes. Owens set seven world records during his career.

Owens eventually went into the public relations business. He worked in community service, especially youth work. Owens traveled widely, giving many speeches that supported clean living, fair play, and patriotism. Owens believed that athletic competition could help solve racial and political problems. William F. Reed

Owensboro (54,067; met. area pop. 91,545), lies in western Kentucky, on the south bank of the Ohio River (see **Kentucky** [political map]). Factories there make automotive frames, chemicals, electrical goods, food products, furniture, liquor, and tobacco products. The city is the home of Brescia University, Kentucky Wesleyan College, and Owensboro Community College.

Owensboro was founded in the late 1790's as Yellow Banks and later renamed in honor of Colonel Abraham Owen, who died in the 1811 Battle of Tippecanoe. The city was incorporated in 1817. It is the seat of Daviess County. Owensboro's government is headed by a manager and a commission. Keith Lawrence

Owl is a type of bird that usually lives alone and hunts for food at night. The owl has been called the "night watchman of our gardens" because it eats harmful rodents at night. Although it is a bird of prey—that is, a bird that kills and eats other animals—it is not thought to be closely related to other birds of prey.

Scientists have identified about 145 species of owls. Owls live throughout the tropical, temperate, and subarctic regions of the world, and they can be found on many oceanic islands.

The smallest species of owl is the tiny *elf owl* of the southwestern United States and western Mexico. It measures about 6 inches (15 centimeters) long. The largest species is the *great gray owl,* which lives in the deep woods of Canada and Alaska as far north as trees grow. It measures about 30 inches (76 centimeters) long and

has a wingspread of 54 to 60 inches (137 to 152 centimeters).

Appearance. A person can recognize any owl at once by its large, broad head with a saucer-shaped ruff of feathers around the eyes. This ruff is called the *facial disk.* It serves to reflect sound to the owl's ear openings. In some species, the facial disk and the ear openings are very large. The eyes of most owls are large and are directed forward, unlike the eyes of most birds. For this reason, owls can watch an object with both eyes at the same time. Like people, they have binocular vision. But unlike people, owls cannot move their eyes in their sockets. Thus, they must move their heads to watch a moving object. Owls have long lashes on their upper eyelids, which they can close over the eyes. Owls' eyes make them look wise, and so the owl has long been a symbol of wisdom. The ancient Greeks believed the owl was sacred to Athena, their goddess of wisdom. Actually, blue jays, crows, jackdaws, and many other birds are probably smarter than owls.

Owls have short, thick bodies; strong, hooked beaks; and powerful feet with sharp claws called *talons.* Some owls have tufts of feathers on their heads. The tufts are often called "ears" or "horns." The feathers of owls are long, soft, and fluffy, and often make the birds seem larger than they are. The plumage is usually dull-colored, so that the bird may blend in with its surroundings.

Way of life. Owls can fly fairly fast. Their feathers muffle the swishing sound that most birds make when they fly. An owl can swoop down on its prey unheard. Some owls can see well enough in the daytime to hunt by day as well as by night. Other owls hunt only at night. Most night-hunting owls have keen vision in the dark. However, some owls have such sensitive hearing that they rely very little on vision. These owls can locate and catch mice, voles, and other small mammals in total darkness by listening to the rustling noise the animals make running through leaves on the forest floor.

Owls eat mostly mammals. The larger owls catch rabbits and squirrels, and the smaller ones catch many mice, rats, and shrews. Owls usually capture their food alive, but now and then they pick up animals that have been recently killed along highways. Some owls also hunt a few birds and insects. Other owls have been known to take fish from shallow waters. Like hawks, owls tear large prey into pieces when they eat it. But if the prey is small enough, they swallow it whole. They later cough up pellets of bones, fur, scales, and feathers, which they cannot digest. These pellets can be found under their nests and roosting places.

Owls are among the most useful birds to farmers. They destroy harmful rodents, such as voles and rats, and also rabbits, which often damage crops. They seldom take poultry, which are usually asleep and inside when owls come out to hunt.

Owls do not build elaborate nests. Their nests are usually old nests of hawks or crows, or crude structures in hollow trees, caves, underground burrows, barns, deserted houses, or belfries. Most female owls lay 3 or 4 eggs, but some lay as few as 1 or as many as 12 eggs. The eggs are nearly round and are white tinged with buff or blue.

Both male and female owls help care for their eggs and young. Young owls have a covering of thick white down. They stay in the nest for 10 to 12 weeks. The larger owls defend the nests against intruders, including people. They sometimes injure people by striking with their sharp talons.

Important owls. There are two families of owls: *barn owls* and *typical owls.* There are 10 species of barn owl. They live in most places except the colder regions. The *common barn owl* lives on all of the continents except Antarctica. In North America, it ranges from the latitude of southern British Columbia and southern Ontario south to Central America. The common barn owl is about 18 inches (46 centimeters) long. This owl is sometimes called the *monkey-faced owl* because its heart-shaped face, beady eyes, and amusing actions seem like those of a monkey. The common barn owl usually nests in a cave or hollow tree. It also may nest in a belfry or the dark places in a barn, which gives it its name.

Typical owls account for about 135 species. The *great horned owl* lives in many places throughout North America. It is common in the forests of the eastern and northern parts of the continent, and among cliffs and canyons of the dry regions in the West. It grows 2 feet (61 centimeters) long and is the only large owl of North America that has tufts of feathers on its head. Like other owls, it is heard more often than seen. It sounds like a barking dog in the distance—*whoo, hoo-hoo, whoo, whoo.*

The great horned owl has been known to kill and eat poultry. However, it helps prevent damage to crops by feeding on rabbits. The great horned owl chooses old crow or hawk nests in which to lay its eggs. Both males and females sit on the eggs at different times. The young great horned owls cannot fly until they are 9 to 10 weeks old.

The *barred owl* lives chiefly in woodlands in the eastern half of North America, from Canada south to Mexico. It is a bit smaller than the great horned owl and has no ear tufts. Brownish-gray bars run across its breast and the length of its belly. The barred owl deserves the name hoot owl more than any other. It gives a series of eight or more loud hoots, the last one ending with an *ah: whoo, whoo, whoo, whoo—whoo, whoo, whoo, whoo-ah.*

The best-known of the small owls are the *screech owls.* These owls measure about 10 inches (25 centimeters) long and are the only small owls with ear tufts. They eat mostly large insects. Most screech owls have from four to six young.

The *eastern screech owl* lives in woodlands east of the Rocky Mountains, from northern Canada to Mexico. Eastern screech owls may be reddish or grayish in color. These owls like to spend the day in hollow trees and to nest there. They may live in a birdhouse if it has a single compartment and an opening 3 inches (8 centimeters) or more across. They often use the trees along city streets and in parks. Eastern screech owls may give no signs that they are around until night. Then they give weird trembling calls and hollow whistles that run up and down the musical scale. Superstitious people think these sounds mean that death or disaster is near. Eastern screech owls eat mostly mice and other small rodents, insects, and sometimes birds.

The adult male *snowy owl* is usually pure white, al-

Some kinds of owls

Owls are good hunters. They see and hear well and can fly almost noiselessly. Many owls build their nests in hollow trees. Others nest on ledges of cliffs or in burrows in the ground. Owls are helpful to people because they eat mice, rats, and other pests.

James R. Fisher, DRK

though it may have brown spots. It measures about 20 inches (51 centimeters) in length. The snowy owl breeds in the Arctic. It may move south in winter, sometimes as far as the Gulf of Mexico.

The *long-eared owl* is another woodland species. It nests in temperate regions of North America, Europe, Asia, and northern Africa. In North America, it flies as far south as Florida for the winter. The long-eared owl grows to about 16 inches (30 centimeters) long. The owl's ear tufts are close together, and it has lengthwise streaks on the breast.

The *northern saw-whet owl* also lives in the woods. Its name comes from its rasping call. In the course of the year, this bird makes its home from Alaska and Nova Scotia south to Mexico. The saw-whet is often tame and can be captured by hand.

Several kinds of owls live in open country and hunt by day as well as night. The *short-eared owl* is about the size of the long-eared owl. It is buff colored all over with many brown streaks. The ear tufts are so short that they are not noticeable. The owl nests in the northern regions of North America, Europe, and Asia, but moves south in the winter. The owl also nests in the southern part of South America. It lives mostly on prairies, meadows, and marshes, and nests on the ground. The *burrowing owl* nests in the ground like a ground squirrel. This owl has long legs that help it walk about, and it can see well in daylight. Burrowing owls often live near colonies of prairie dogs because they frequently use old prairie dog burrows as nesting sites.

Scientific classification. Owls belong to one of two families, the barn owl family, Tytonidae, or the typical owl family, Strigidae. The scientific name for the common barn owl is *Tyto alba.* The barred owl is *Strix varia;* the eastern screech owl, *Otus asio;* the long-eared owl, *Asio otus;* the northern saw-whet owl, *Aegolius acadicus,* and the short-eared owl, *Asio flammeus.*

Owyhee Dam, *oh WY hee,* is one of the larger concrete arch gravity dams in the world. It lies on the Owyhee River in Oregon, about 11 miles (18 kilometers) southwest of Adrian, Ore., near the Idaho state line. The dam is 417 feet (127 meters) high and 830 feet (253 meters) long. It can store about 1.1 million acre-feet (1.4 billion cubic meters) of water. It forms a reservoir 52 miles (84 kilometers) long which stores water for irrigating about 16,000 acres (6,470 hectares) of land. This dam was built by engineers of the United States Bureau of Reclamation. It was completed in 1932 at a cost of $6,671,000.

Larry W. Mays

Ox. Oxen include domestic cattle, water buffalo, bison, musk oxen, brahman, yak, banteng, and other members of the bovine family. Most oxen first came from Asia and Europe. The musk ox and bison are natives of North America. South America, Australia, and Madagascar have no native oxen.

Oxen have heavy bodies, long tails, and divided hoofs, and they chew their cud. Their smooth horns stand out from the side of the head, and are curved.

Domestic oxen give meat, milk, and leather. Domestic oxen are very powerful work animals, and they serve as beasts of burden in some parts of the world.

Scientific classification. The different kinds of oxen belong to the bovid family, Bovidae. Domestic cattle are *Bos taurus.*

Oxalic acid, *ahk SAL ihk,* is a strong organic acid found in many vegetables and other plants. It occurs abundantly as its potassium salt in the sap of dock and other plants in the oxalis and rumex plant groups. It is found in spinach, rhubarb, tomatoes, grapes, and sweet potatoes. Oxalic acid is also produced in the body. It has been known since early times.

Industry uses oxalic acid in processing textiles, bleaching straw hats, and removing paint and varnish. It is widely used in chemistry as an analytical reagent. Oxalic acid forms substances called *complexes* with various metals, especially iron. For this reason, it is also used as a rust and scale remover.

The acid is prepared commercially by heating sodium formate with sodium hydroxide or by bubbling carbon monoxide gas into a concentrated sodium hydroxide solution.

Oxalic acid occurs as clear, colorless crystals, soluble in water. It is highly poisonous if swallowed. Its chemical formula is $(COOH)_2 \cdot 2H_2O$, and it melts at 101.5 °C (215 °F). This formula is the dihydrate form, as shown by the two water molecules. When heated to 212 °F (100 °C), the crystals lose the water and have the formula $(COOH)_2$ (see **Hydrate**). Roger D. Barry

See also **Acid; Oxalis.**

Oxalis, *AHK suh lihs,* is the name of a large group of plants that grow chiefly in South Africa and South America. There are about 850 species of oxalis. Many species grow as weeds. However, some species are cultivated as ornamental plants and are grown in hanging baskets, window gardens, or rock gardens.

Most kinds of oxalis grow from bulbs, from rootlike *rhizomes,* or from thickened underground stems called *tubers.* They have showy flowers that may be white or a variety of pastel colors. The leaves are shaped somewhat like clover leaves. Both the leaves and flowers close up at night. The leaves taste sour because they

E. R. Degginger

An oxalis has clover-shaped leaves and colorful blossoms. The leaves and the flowers close up at night.

contain *oxalic acid.* The acid is so named because it comes from the oxalis plant. The leaves of some kinds of oxalis can be used in salads. One species of oxalis is cultivated in South America for its edible tubers.

August A. De Hertogh

Scientific classification. Oxalis belong to the wood-sorrel family, Oxalidaceae. They make up the genus *Oxalis.*

Oxbow lake is a crescent-shaped lake that forms when a river channel is cut off from the main stream. Such a lake forms when a river changes its course to a more direct path to the sea. The river leaves deposits of earth at either end of the curve, and these deposits eventually separate it from the main stream. Oxbow lakes are often rather shallow. They may become filled with sediments

An oxbow lake, *center,* was once a part of the river in the foreground. Deposits of earth have cut it off from the main stream.

from river floods and decayed vegetation, and so disappear. Many oxbow lakes are found in Louisiana, Arkansas, and Mississippi along the Mississippi River and some of its slow-moving branches. J. M. Coleman

Oxen. See Ox.

Oxenstierna, *UK suhn SHAIR na,* **Axel Gustafsson** (1583-1654), a Swedish statesman, was friend and adviser to King Gustavus Adolphus. Oxenstierna's brilliance as a statesman helped the king achieve great military victories. As chancellor, Oxenstierna directed Sweden's political affairs from 1612 until his death. This period marked Sweden's greatest influence in Europe.

Oxenstierna carried out important diplomatic missions for Gustavus Adolphus during the Thirty Years' War (1618-1648), a struggle between Roman Catholics and Protestants. After Gustavus died in battle in 1632, Oxenstierna directed Sweden's foreign affairs and provided vital leadership throughout the war. From 1636 to 1644, he headed the *regency* (temporary ruling group) that ruled Sweden during Queen Christina's childhood. Oxenstierna was born in Fåno, Sweden.

Theodore S. Hamerow

Oxford, England (pop. 115,000), is the seat of Oxford University. The university, which began to develop in the 1100's, is the oldest British university (see **Oxford University**). The city lies between the rivers Thames and Cherwell, about 50 miles (80 kilometers) northwest of London (see **England** [political map]).

The original center of the city was probably a home for nuns that was founded in the 700's. The home was on the present site of the cathedral at Oxford University. Oxford is now an important industrial center, with automobile factories on the outskirts of the city.

Peter R. Mounfield

Oxford Movement is the name given to a revival in the Church of England that began in 1833 at Oxford. A powerful sermon was preached by John Keble (1792-1866), who tried to show the people the evils that were threatening the church because of their indifference and ignorance. Two leaders joined Keble in the Oxford Movement. One was the brilliant John Henry Newman, and the other was the learned Edward B. Pusey (1800-1882).

These leaders preached and wrote for a number of years, seeking to impress on the people that the church was "more than a merely human institution; that it had privileges, sacraments, a ministry ordained by Christ; that it was a matter of the highest obligation to remain united to the Church."

The leaders of the Oxford Movement wrote a series of essays called "Tracts for the Times." These essays were widely read and the movement grew. But in 1841 Newman wrote a tract which was so decidedly Catholic that the Anglican bishops condemned it. In 1845, Newman joined the Roman Catholic Church, and was eventually made a cardinal.

John Keble and Edward B. Pusey continued the work of the Oxford Movement, and new leaders took it up. A notable book, called *Lux Mundi* (*Light of the World*), edited by Charles Gore, afterward Bishop of Oxford, was published in 1889. It created a great stir throughout the Anglican Communion.

The Oxford Movement had great influence upon the Anglican world, including the Episcopal Church in the United States. It revived faith in the church as the divine society, not to be controlled by the state. It made the office of the pastor more important. The movement increased the importance of tradition and the sacraments. It extended the work of the church among the poor in larger cities. In general, it also awakened church and laity to a broader view of their power and duty.

Peter W. Williams

See also **Church of England; Newman, John Henry Cardinal; Wilberforce, Samuel.**

Oxford University is the oldest university in the United Kingdom and one of the world's most famous institutions of higher learning. Oxford University started to develop during the 1100's. It is in Oxford, England, about 50 miles (80 kilometers) northwest of London.

The university has over 13,000 students. It consists of 35 colleges, plus 5 *private halls* established by various religious groups. Three of the 5 private halls are for men only. Of the colleges, St. Hilda's is for women, and the rest are for men and women. The coeducational colleges include All Souls, Christ Church, Jesus, Lady Margaret Hall, Magdalen (pronounced *MAWD lihn*), Nuffield, St. John's, Somerville, and Trinity.

At Oxford, each college is a corporate body distinct from the university and is governed by its own head and *fellows.* Most fellows are college instructors called *tu-*

tors, and the rest are university professors, readers, and lecturers. Each college manages its own buildings and property, elects its own fellows, and selects and admits its own undergraduate students. The university provides some libraries, laboratories, and other facilities, but the colleges take primary responsibility for the teaching and well-being of their students.

Educational program. Each student at Oxford is assigned to a tutor, who supervises the student's course of study, primarily through *tutorials.* Tutorials are weekly meetings of one or two students with their tutor. Students may see other tutors for specialized instruction. They may also attend lectures given by university teachers. Students choose which lectures to attend on the basis of their own special interests and on the advice of their tutor.

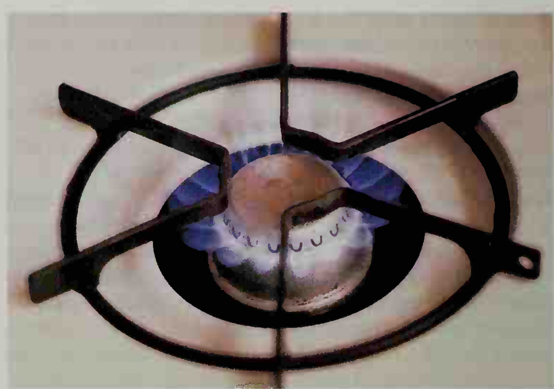
The university, not the individual colleges, grants degrees. The first degree in the arts or sciences is the Bachelor of Arts with honors. Oxford also grants higher degrees, diplomas, and certificates in a wide variety of subjects.

The Rhodes scholarship program enables students from the United States, Canada, and many other nations to study at Oxford for a minimum of two years (see **Rhodes scholarship**). The British government grants Marshall scholarships to citizens of the United States for study at Oxford and other universities that are located in Britain.

History. During the 1100's, a university gradually developed from a number of schools in the city of Oxford. Its development was aided by a break in relations between England and France in 1167. Hostility between the two nations prevented English students from attending the University of Paris, and many of them went to Oxford instead. The university received its first official recognition in 1214.

The three oldest Oxford colleges—University, Balliol, and Merton—date from the 1200's. Twelve more colleges were founded between 1300 and 1555. The first colleges for women were established during the late 1800's. The university did not grant degrees to women until 1920. P. A. McGinley

See also **Architecture** (Gothic revival; picture); **Bodleian Library; Europe** (picture).



Oxidation, *AHK suh DAY shuhn,* is a chemical reaction in which a substance loses electrons. The term originally referred to any chemical process in which a substance combines with oxygen. This definition of oxidation was formulated by chemists before they discovered that some reactions of this kind could occur without oxygen.

The electrons released during oxidation must be captured by another substance. Thus, oxidation is always accompanied by a reaction called *reduction,* in which a substance gains electrons. The combined transfer of electrons is often called a *redox process.* See **Reduction.**

Oxidation can be demonstrated by heating iron and sulfur together. In this case, each neutral iron atom (Fe) loses two electrons and becomes an iron ion (Fe^{2+}). The chemical equation for the oxidation of iron can be written:

$$Fe \rightarrow Fe^{2+} + 2e$$

The electrons released during oxidation are immediately picked up by sulfur atoms, resulting in the formation of sulfide ions (S^{2-}). These sulfide ions combine with the iron ions to form the compound iron sulfide (FeS).

WORLD BOOK photo by Dan Miller

Oxidation with oxygen occurs when oxygen combines with another substance. In a gas flame, *above,* oxygen combines rapidly with the carbon and hydrogen in methane, producing carbon dioxide gas and water vapor.

Alice Dole

Rust can result from oxidation with oxygen. Metal rusts, *above,* when iron combines slowly with oxygen and water.

The rusting of iron is a common example of the original meaning of oxidation. Iron combines with oxygen in the presence of moisture to form rust. Another example is the formation of such air pollutants as nitrogen oxides and sulfur oxides. Nitrogen oxides are produced when oxygen combines with nitrogen in hot, fuel-burning automobile engines. Sulfur oxides form when oxygen reacts with sulfur in coal-burning furnaces.

Oxidation also occurs inside the human body when food molecules combine with inhaled oxygen to slowly produce carbon dioxide, water, and energy. The combustion of natural gas and other fossil fuels is a form of rapid oxidation. Cathleen J. Hapeman

Antioxidant	Fire
Combustion	Oxide
Corrosion	Rust

Oxide, *AHK syd,* is a chemical compound of oxygen with some other element. Oxides are commonly formed when the elements are oxidized. For example, burning the carbon present in coal or wood gives carbon dioxide (CO_2) and carbon monoxide (CO). Burning is rapid

oxidation. Carbon dioxide is also formed by slow oxidation processes in animal cells, and it is exhaled from the lungs. The rusting of iron is slow oxidation. Rust contains ferric oxide (Fe_2O_3).

Metallic oxides combine with water to form basic hydroxides, while nonmetallic oxides with water form oxygen acids. The oxides of sulfur and nitrogen are used to form sulfuric and nitric acids.

Sulfur dioxide and nitrogen oxides pollute the air when given off by automobiles, by factories, and by power plants that burn coal or oil. They also mix with moisture in the air to form sulfuric and nitric acids, which fall as *acid rain* (see **Acid rain**). Acid rain damages plants, wildlife, and certain building structures.

Calcium oxide is *quicklime* (CaO). When mixed with water it forms the *slaked lime* used in whitewash and plaster. Sand, which is important in glassmaking, is one form of *silicon dioxide,* called silica (SiO_2). Other forms of silicon dioxide are quartz, onyx, and opal.

Cathleen J. Hapeman

Oxidizer. See **Rocket** (Rocket propellant; Liquid-propellant rockets).

Oxnam, G. Bromley (1891-1963), was a bishop of the Methodist Church. He served as bishop of the Washington, D.C., area from 1952 to 1960, when he retired. Oxnam's books and speeches emphasized his liberal social beliefs. They favor justice for laborers and equal rights for all classes.

Garfield Bromley Oxnam was born in Sonora, California. Oxnam was ordained a Methodist minister in 1916. He taught at the Boston University of Theology from 1927 to 1928. Oxnam served as president of DePauw University in Greencastle, Indiana, from 1928 to 1936. He was bishop of the Omaha area from 1936 to 1940, of the Boston area from 1940 to 1944, and of the New York area from 1944 to 1952. Charles H. Lippy

Oxyacetylene. See **Acetylene.**

Oxygen is a life-supporting gas and a chemical element. Nearly all living things need oxygen to stay alive. Oxygen combines with other chemicals in plant and animal cells to produce energy needed for life processes. Oxygen is also needed to make most fuels burn. During the burning process, oxygen combines with the fuel in a chemical reaction. Heat is released during the burning process.

Oxygen is one of the most plentiful chemical elements on the earth. It makes up about a fifth of the volume of air. Nitrogen makes up most of the other four-fifths. Oxygen is also found in the earth's crust and in water. This oxygen is not pure, but is combined with other elements. On the average, 100 pounds of the earth's crust contains about 47 pounds of oxygen. Nearly half of the weight of most rocks and minerals is oxygen. Every 100 pounds of water contains about 89 pounds of oxygen. Hydrogen makes up the other 11 pounds of water.

Chemical properties. Oxygen has an atomic number of 8 and an atomic weight of 15.9994. Its chemical symbol is O. Ordinary oxygen molecules, such as those that make up about 20 per cent of the atmosphere, have two oxygen atoms bonded together. This ordinary oxygen, O_2, is colorless, odorless, and tasteless. Oxygen molecules that have three oxygen atoms make up a gas called *ozone,* O_3. Oxygen combines with many other elements, forming compounds called *oxides* (see **Oxide**).

Ordinary oxygen changes to a pale blue liquid when cooled to its boiling point, −182.962 °C at atmospheric pressure. Oxygen liquefies at a higher temperature when the pressure is increased. At a pressure of 730 pounds per square inch (51 kilograms per square centimeter), oxygen liquefies at −118.8 °C. These values of temperature and pressure are oxygen's *critical temperature and pressure.* It is impossible to liquefy oxygen at a higher temperature at any pressure. Liquid oxygen is magnetic and can be held between the poles of a strong magnet. It freezes at −218.4 °C.

How oxygen supports life. Only a few kinds of living things, including certain germs, can live without *free* (chemically uncombined) oxygen, O_2. Human beings and the other land animals get oxygen from the air. Fish and most other water animals get dissolved oxygen from water.

Free oxygen enters a person's bloodstream through the lungs. It enters a fish's bloodstream through the gills. The blood carries oxygen to the cells of the body. In the cells, oxygen combines with chemicals obtained from food. Energy produced during this process makes it possible for each cell to perform its function in the body. Carbon dioxide is produced in the cells as a waste product (see **Respiration**).

Some people believe that breathing pure oxygen will lead to an early death. They think the body's cells will use oxygen too fast, causing a person to die of exhaustion. But in certain situations, breathing pure oxygen may be necessary. For example, pilots who fly at high altitudes, where the air is too thin to supply enough oxygen, breathe from tanks of pure oxygen.

Plant cells use oxygen in much the same way that animal cells do. Plant cells also make oxygen in the process of *photosynthesis.* During this process, the cells use the energy of sunlight to make sugar from carbon dioxide and water. Oxygen is produced as a by-product, and is released into the atmosphere. Scientists believe that all of the air's oxygen has been formed from water by this process over billions of years.

Other uses of oxygen. Oxygen has many uses in industry. Some steel is manufactured by the *basic oxygen process.* In this process, a stream of high-pressure oxygen blasts down on melted pig iron and burns out impurities. Welders mix oxygen with fuel in their torches to produce an extremely hot flame with a temperature of about 6000 °F (3300 °C).

Liquid oxygen, called *LOX,* is used in rockets propelled by liquid fuels. LOX combines with various fuels, including kerosene and liquid hydrogen, to produce the rocket's *thrust* (pushing force). LOX is also mixed with other fuels to make explosives for blasting.

Making oxygen. Most commercial oxygen is distilled from liquid air. During the distillation process, the nitrogen boils before the oxygen does, because nitrogen has a lower boiling point. As the nitrogen boils away, the liquid air is left with a greater concentration of oxygen. Commercial oxygen is stored in steel tanks at a pressure of about 2,000 pounds per square inch (140 kilograms per square centimeter), more than a hundred times the pressure of the atmosphere.

Small amounts of oxygen can be made by heating po-

tassium chlorate. A little manganese dioxide added to the potassium chlorate speeds up the formation of oxygen.

History. Oxygen was discovered by two chemists working independently. They were Carl Scheele of Sweden and Joseph Priestley of England. Scheele's laboratory notes show that he prepared oxygen in the early 1770's by heating various compounds, including saltpeter and mercuric oxide. Scheele's experiments were not published until 1777. Priestley, however, had published his experiments with oxygen in 1775 and published further observations concerning the gas in 1777. He described how he prepared oxygen in 1774 by heating mercuric oxide.

Scheele called oxygen *fire air.* Priestley called it *dephlogisticated air.* In 1779, the French chemist Antoine Lavoisier named the gas *oxygen.* The word means *acid producer.* Lavoisier and others had found that oxygen is a part of several acids. Lavoisier incorrectly reasoned that oxygen is needed to make all acids. He combined the Greek words *oxys* (meaning *sharp* or *acid*) and *gignomai* (meaning *produce*) to form the French word *oxygene.* This word is *oxygen* in English. Frank C. Andrews

Oxygen tent is a device that has been used in medicine for patients who require more oxygen than is normally contained in the air. Oxygen tents were once used extensively to treat oxygen deficiencies in infants and children. Physicians seldom use oxygen tents today.

Oxygen tents are made of plastic or other material through which oxygen cannot pass. Oxygen enters the tent through a hose. Some tents are dome-shaped hoods large enough to completely cover an infant. Others can cover an entire bed.

Newer methods of administering oxygen allow doctors and nurses to reach the patient more easily. Oxygen may be given through tubes inserted into the nostrils, or through a mask placed over the nose and mouth. Newborns may receive oxygen through a plexiglass hood placed over the head. Patients who have severe difficulty breathing may need machines called *respirators* (see **Respirator**). People with carbon monoxide poisoning may be placed in a *hyperbaric chamber,* an airtight compartment in which oxygen is provided at pressures greater than atmospheric pressure. Gerald B. Merenstein

Oyster is a type of shellfish that provides an important source of food and pearls. The soft, edible body of an oyster is protected inside a hard, two-piece shell, which is usually irregular in shape. An oyster spends all except the first few weeks of its life attached to rocks and other hard surfaces on the ocean bottom. Oysters are found in relatively calm waters of mild to tropical coastal oceans, where they often form large reefs.

People began eating oysters thousands of years ago. About 100 B.C., the ancient Romans raised oysters on "farms" along the coast of Italy. Later, Roman settlers in England collected oysters along the coast. In winter, they placed the shellfish in cloth bags filled with ice and snow and sent them to Rome. Today, oyster farms are common along parts of the United States and European coasts.

Oysters—like clams, scallops, and some other shellfish—are a type of *mollusk,* a group of soft-bodied animals that have no bones. Oysters are called *bivalve* (two valve) mollusks because their shell is made up of two parts called *valves.*

There are several different groups of oysters. One family of oysters includes pearl oysters, which produce high-quality pearls, and wing oysters. The oysters most often eaten by human beings belong to the family known as true oysters. They are the most abundant and well-known family and are found worldwide. This article chiefly deals with true oysters.

The body of an oyster

Shell. The valves of an oyster's shell are held together by an elastic ligament at the hinge. One valve is deeper, larger, and thicker than the other. This large valve is the one that the animal normally fastens to the ocean bottom.

The elastic ligament usually keeps the valves slightly apart. A strong muscle called an *adductor* closes the shell. When threatened or during long periods out of the water, oysters close their valves tightly. They can live with their shell closed for several weeks.

An oyster's shell is made of a hard, chalky material called *calcium carbonate.* The shell is produced by a skinlike organ called the *mantle,* which lines the inside of the shell. The mantle takes minerals from the food the oyster eats and uses them to produce the shell. Because the mantle makes shell in cycles, periods without shell growth leave a line. The distinct shell lines can be used like the rings of a tree to estimate the age of an oyster. The shell grows as long as the oyster's body grows.

The inside of the shell is white with colored highlights. The shell of a pearl oyster is lined with a smooth, shiny substance called *mother-of-pearl.* A scar inside the shell indicates where the adductor muscle was attached.

Sometimes a tiny piece of grit or other foreign substance can work its way between the mantle and the shell, irritating the mantle. The irritation stimulates the production of a pearl. Shell material is evenly laid down around the particle to stop the irritation. In this way, a pearl is formed. Pearl oysters can produce high-quality pearls and are the primary source of pearls. True oysters rarely produce pearls. When they do, the pearls are dull in color, irregular in shape, and of little value.

Body organs. An oyster, like all bivalves, does not have a head. A pair of W-shaped gills is located beneath the mantle. The oyster uses its gills, which are covered with fine, hairlike *cilia,* to breathe and to trap small food particles. Water flow created by the cilia brings tiny, single-celled plantlike organisms called *phytoplankton* toward the gills. The cilia direct the food to the mouth. The food then moves into the oyster's stomach and final digestion takes place in the digestive gland.

The oyster's heart pumps blood to all parts of its body. A pair of kidneys removes chemical wastes.

An oyster has a simple nervous system made up of a few nerve bundles and connecting nerves. An oyster does not have eyes. However, it does have two rows of sensitive *tentacles* (feelers) along the mantle edge that can sense changes in light, chemicals in the water, and

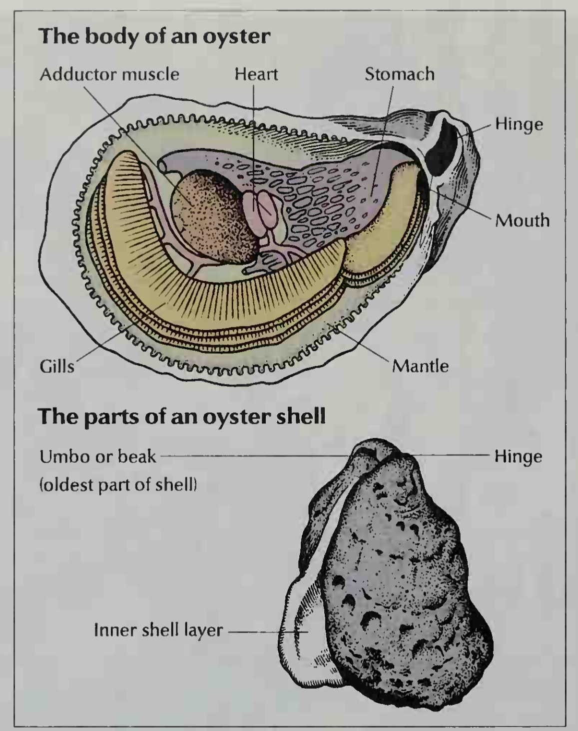
Oysters fasten their shells to rocks or other hard objects on the ocean bottom. Most species live in shallow coastal waters.

water currents. Any change will cause the tentacles to *contract* (become smaller). In response, the adductor muscle quickly closes the shell against possible danger.

The life of an oyster

Many kinds of oysters are *hermaphrodites* (pronounced *hur MAF ruh dyts*)—that is, animals with both male and female reproductive organs. Certain oysters begin their life as males but later develop into females. Other kinds alternate between male and female several times during their lives. During the female stage, various oysters can produce as many as 500 million eggs each year. Male oysters release sperm, which unite with and fertilize the eggs. In many oysters, the eggs are fertilized after the female releases them into the water. In others, the sperm enter the female's body to fertilize the eggs.



Young. The earliest part of an oyster's life is spent drifting in water as part of the mass of tiny organisms called *plankton.* An oyster larva develops from the fertilized egg. After about 24 hours, the larva is called a *veliger (VEE luh juhr).* Veligers use their cilia to move. A tiny bivalve shell is visible.

Veligers remain floating in the water for about two weeks. During this time, the animal continues to develop and forms a muscular "foot" that extends between the valves. The animal is now called a *pediveliger (PEHD uh VEE luh juhr).* The foot is used to test different surfaces as the oyster searches for an appropriate site to settle. An oyster usually chooses a hard surface, such as a rock or the shell of another animal. It then attaches itself permanently to the surface using cement produced by its body. Most pediveligers settle with adult oysters, and together they often form crowded *beds* (groups) in coastal inlets.

Young oysters grow quickly. They lose their foot shortly after they settle. A month-old oyster is about the size of a pea. A year-old oyster is approximately 1 inch (2.5 centimeters) in diameter. Oysters usually grow at a rate of an inch per year for three or four years. After this time, their growth rate slows. Some North American oysters grow as large as 14 inches (36 centimeters). Most oysters live about 6 years, but some can survive more than 20 years.

Enemies. An oyster has many enemies and no defense except its shell. Diseases caused by various viruses and *protozoa* (single-celled organisms) can kill millions of oysters in a single year. Most newly hatched oysters are eaten by fish.

Once settled, even adult oysters fall prey to many animals. Starfish use their tube feet to pull at the oyster's valves, which eventually causes the adductor muscle to weaken and the shell to open slightly. The starfish then eats the soft oyster meat. Many crabs with powerful claws and some fish with strong jaws are able to crack

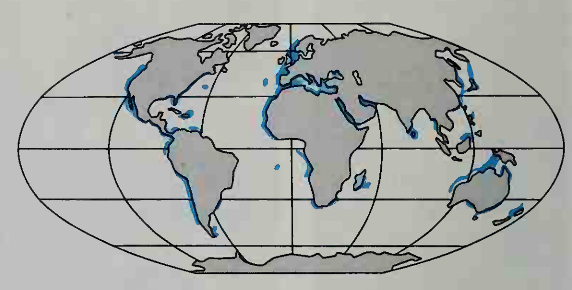
the shells of small oysters. An oyster-drill snail uses a combination of glandular chemicals and filelike tongue to make a hole in an oyster's shell. Once the hole is made, the snail sucks out the oyster meat. Some birds, such as the oystercatcher, can pry an oyster's shell apart with their strong beaks.

People are the greatest enemies to oysters. They collect and eat millions of oysters each year. Overfishing and pollution have reduced the stock of oysters.

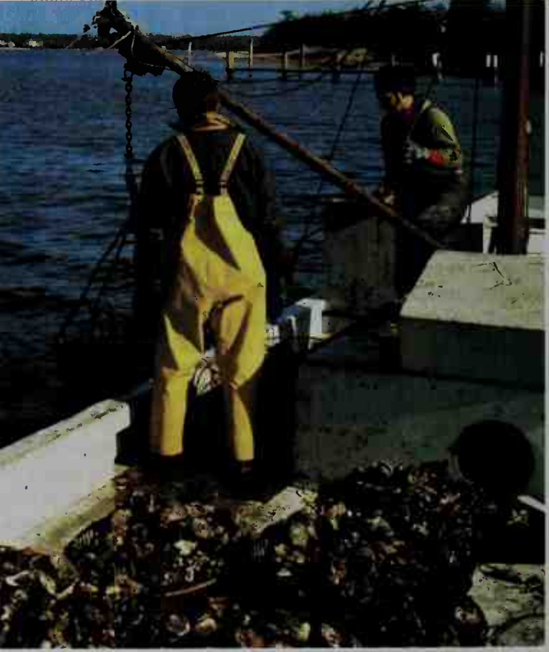


The oyster industry

Oyster farming. The popularity of oysters as food—and the threat to their natural populations—has led to the growth of oyster farming. Most oyster farms are established in shallow, quiet coastal waters where there is a firm ocean bottom. Shifting sand or mud can cover and smother oysters. Floats mark a farmed area. Oyster farmers place old shells or tiles on the bottom to act as *cultch,* a surface to which the young oysters can attach themselves. Farmers often buy seed oysters to "plant" in the farming areas. Workers harvest the crop when the oysters are 2 to 4 years old and 2 to 4 inches (5 to 10 centimeters) in diameter.

Many oysters raised for market come from commercial oyster farms. Large oyster-farming centers include those along the southwest coast of France and the west coast of the United States. Oyster farmers raise and gather the shellfish along the entire coast of the United States. Louisiana, Maryland, Virginia, and Washington are the leading oyster-producing states. In Canada, the provinces of British Columbia and Prince Edward Island produce the most oysters. South Korea, Japan, the United States, and France are the leading oyster-producing countries.

Where oysters are found



The blue areas of the map show the parts of the world where edible oysters are found. The map includes oyster farm areas.

Oyster harvesting is heaviest during fall and winter in most regions. Farmers use long tongs to collect oysters in shallow waters. In deeper waters, they gather the oysters with *dredges,* which are nets attached to metal frames. The dredges are attached to a boat by a line and dragged along the bottom.

Oysters are sold either in their shells or unshelled. Workers called *shuckers* remove the shell from the oyster. A shucker forces the valves apart and then cuts the adductor muscle. The workers remove the meat from the opened shell and pack the meat for shipment.

Oyster meat. People eat oysters fried, broiled, *scalloped* (baked in sauce), and prepared many other ways. Oysters are rich in protein and in several minerals and vitamins. But the U.S. Food and Drug Administration advises that people with diabetes, weakened immune systems, or other medical conditions should avoid eating raw oysters. People once believed that oysters were un-

Oystercatcher is the name of a family of wading birds that live on seacoasts. The name comes from the bird's sharp, chisel-shaped bill. The oystercatcher uses its bill to open the shells of such mollusks as mussels and oysters, and to pry limpets from rocks.

WORLD BOOK illustration by Trevor Boyer, Linden Artists Ltd.

The oystercatcher uses its sharp bill to open mollusks.

The *American oystercatcher* lives on the Atlantic coast from the northern United States to Argentina, and on the Pacific coast from Lower California to Chile. It is smoky-brown with white underparts and a black head and neck. The *American black oystercatcher* lives on the Pacific coast from Alaska to Lower California. The *common oystercatcher* lives in Europe, Asia, Africa, and Australia. Females lay three or four eggs among pebbles.

George L. Hunt, Jr.

Scientific classification. Oystercatchers make up the oystercatcher family, Haematopodidae. The American oystercatcher is *Haematopus palliatus.*

Ozark Mountains, *OH zahrk,* are a range of hills extending from southern Illinois across Missouri and into Arkansas and Oklahoma. The Ozarks rise from 1,500 to 2,300 feet (457 to 701 meters) above sea level. Their highest peaks are the Boston Mountains of Arkansas. The Ozarks are part of the Ozark region, which also includes areas of flatland. The region covers about 40,000 square miles (100,000 square kilometers). The hills are covered with timber. There are many caves in the areas where the hills are made of limestone. The Ozarks of southeastern Missouri contain the most important lead mines in the United States. Mines in the Ozarks also produce iron and barite. The raising of beef cattle is the most important agricultural activity over most of the Ozark region. Farmers raise dairy cattle on the Springfield Plateau in southwest Missouri. Crops grown in the Ozark region include apples, grapes, peaches, and wheat. Tourism is a major source of income in many parts of the region.

Ozawa, *oh ZAH wah,* **Seiji,** *SAY jee* (1935-), is one of the outstanding orchestra conductors of his time. He established his reputation with a broad range of music, including that of many modern Japanese composers.

Ozawa was born on Sept. 1, 1935, in Hoten, in northeastern China. He went to Europe in 1959 and studied with the Austrian conductor Herbert von Karajan in West Berlin. There, Leonard Bernstein, conductor of the New York Philharmonic Orchestra, observed Ozawa and named him one of the orchestra's three assistant conductors for the 1961-1962 season. Bernstein recalled him as sole assistant conductor for the 1964-1965 season. Ozawa was the Toronto Symphony's conductor from 1965 to 1969 and the San Francisco Symphony's music director from 1968 to 1976. He served as artistic and music director of the Boston Symphony from 1973 to 2002. In 2002, Ozawa became director of the Vienna State Opera. Charles H. Webb

Ozick, Cynthia (1928-), is an American author whose works consistently address fundamental questions of Jewish life. Ozick often incorporates Jewish myth and lore into modern circumstances in her novels, short stories, and essays. Her major themes include the shadow of the Holocaust over Jewish identity, the tensions between heritage and assimilation among Jewish immigrants, and the moral significance of storytelling.

Ozick believes "that stories ought to judge and interpret the world." The influence of the American author Henry James appears in Ozick's specific, deliberate attention to fiction as a forum for social and philosophical ideas. Ozick has written the novels *Trust* (1966), *The Cannibal Galaxy* (1983), and *The Messiah of Stockholm* (1987). Her short fiction has been collected in *The Pagan Rabbi* (1971), *Bloodshed* (1976), *Levitation* (1982), and *The Shawl* (1989). Ozick also writes about her concerns with the civilizing responsibilities of literature in the essays collected in *Art and Ardor* (1983), *Metaphor and Memory* (1989), *What Henry James Knew* (1993), *Fame and Folly* (1996), and *The Puttermesser Papers* (1997). A collection of autobiographical essays was published as *Quarrel & Quandry* (2000). Ozick was born on April 17, 1928, in New York City. Arthur M. Saltzman

Ozone is a gas that is present in small amounts in Earth's atmosphere. In the *troposphere* (the lowest level of the atmosphere), ozone is a pollutant. It can harm plant and animal tissues, and it can damage rubber and plastic. Ozone in the *stratosphere* (the layer above the troposphere) blocks harmful ultraviolet rays from the sun, protecting life on Earth. Every spring in the Southern Hemisphere since the late 1970's, scientists have observed a depletion of the ozone layer over Antarctica. The region of decreased ozone is called the *ozone hole.*

Ozone is related to the oxygen molecules that sustain life. An oxygen molecule has two oxygen atoms and the chemical formula O_2; an ozone molecule has three oxygen atoms and the formula O_3. Pure ozone is a pale blue gas. The word *ozone* comes from a Greek word meaning *to smell,* reflecting ozone's sharp, irritating odor.

Ozone occurs naturally through *photochemical reactions* and by *electrical discharges.* In photochemical reactions in the stratosphere, ultraviolet rays from the sun strike oxygen molecules, breaking each molecule into two oxygen atoms. The oxygen atoms combine with other oxygen molecules, forming ozone. Electrical discharges include lightning and sparks from motors. Such discharges can break up oxygen molecules, leading to ozone formation. Near Earth's surface, reactions between such gases as nitrogen oxides and hydrocarbons create ozone and other ingredients of a dangerous pollutant called *photochemical smog.*

Commercial applications of ozone include the bleaching of pulp in paper mills and the purification of water. Manufacturers produce ozone by creating electrical discharges in a machine.

Ozone's *relative molecular mass* (formerly called *molecular weight*)—that is, its amount of matter compared to that of the most common form of carbon—is 47.998. The German chemist Christian Friedrich Schönbein discovered ozone in 1840. Linnea M. Avallone

Ozone hole is a region of the atmosphere over Antarctica where a protective layer of ozone gas, a form of oxygen, becomes less concentrated every spring. The ozone layer blocks harmful ultraviolet rays from the sun, protecting life on Earth.

The ozone layer is roughly 10 miles (16 kilometers) thick. The bottom of the layer is about 6 miles (10 kilometers) above the North and South poles. When the gas becomes less concentrated, those dimensions remain about the same, but the number of ozone molecules in the layer decreases. Scientists say that the layer is *depleted.*

Scientists monitoring the atmosphere over Antarctica first noticed ozone depletion in the late 1970's. In 1985, researchers led by the British atmospheric scientist Joseph C. Farman showed that the ozone hole had grown since the 1960's. That is, over the years, the area of low concentrations of ozone had become larger. In addition, the ozone concentrations had become smaller.

A combination of cold weather and chemical activity creates an ozone hole every year. The cold weather creates ice surfaces on which certain chemical reactions can take place. The chemical activity begins when chemicals called *chlorofluorocarbons* (CFC's) break apart, creating molecules that take part in the reactions.

Most of Antarctica receives little or no sunshine from April through August, so the air becomes extremely cold. In addition, a powerful wind known as the *polar jet* prevents the cold air from mixing with warmer air to the north. As a result, ice clouds form in the ozone layer.

CFC molecules rise to the upper atmosphere, where ultraviolet rays break them up into smaller molecules. The smaller molecules, in turn, take part in chemical reactions on ice particles in the clouds. Those reactions create molecules that destroy ozone in the presence of sunlight.

Between August and October of each year, the number of ozone molecules in the ozone layer over Antarctica decreases by about two-thirds. The reactions that deplete the layer stop around the end of November—late spring in Antarctica. The polar jet also weakens, helping to return ozone concentration to normal.

Ozone depletion also occurs over the Arctic. However, depletion there is usually less severe because Arctic air is not as cold as Antarctic air.

CFC's do not occur in nature. Instead, they are industrially produced. They were once widely used as refrigerants and as propellants in aerosol spray cans. By international agreement, most countries have halted the production of CFC's. But an ozone hole occurs every year because of CFC molecules that remain in the atmosphere. Linnea M. Avallone
